11. M. *piperita*. Pepper Mint. Sm. Fl. Brit. n. 4. Engl. Bot. t. 687. Hudſ. 251. Woodv. Med. Bot. t. 169. Sole Menth. t. 7, 8, and 24. Ehrh. Pl. Off. 216. Willd. n. 13. (M. spicis brevioribus et habitioribus, foliis Menthæ fuscæ, sapore fervido piperis; Raii Syn. 234. t. 10. f. 2.)—Leaves stalked, ovate, smoothish. Spikes obtuse, interrupted in their lower part. Calyx very smooth at the base.—Native of watery places in various parts of England, but it seems not to have been found wild any where else. In gardens it is every where cultivated, for the sake of its valuable medicinal properties, which are of a stimulating or stomachic kind, and exist in great perfection in the essential oil and distilled water. It appears by the Linnæan herbarium, and we think also by the Mat. Med. of Bergius, 516, though his description unfortunately omits what would absolutely decide the question, that the Pepper Mint cultivated in Sweden is not our's, but a high-flavoured variety of *M. hirsuta*, which, even in the old Linnæan specimen, still retains the taste of real Pepper Mint. Its *calyx* is entirely clothed with ascending hairs, the *flower-stalks* with deflexed ones, the essential characters of *M. hirsuta;* whereas the *piperita* has the *calyx-teeth* only hairy, the lower part of the *calyx*, and that of the *stalks*, being always remarkably smooth and polished. Hence it appears why Linnæus reckoned his *piperita* among the capitate species. Our's is truly spiked, though the spikes vary in length, and are usually blunter than in the *sylvestris* and *rotundifolia*. Mr. Sole's plates well display the two extremes, but we can easily trace one variety into the other.

The *stem* of *M. piperita* is generally two or three feet high, purplish, with some scattered deflexed hairs, and numerous opposite branches. *Leaves* on stalks of a moderate length, ovate, acute, more or less elongated, and varying from one to three inches in length, sharply serrated; dark green and nearly smooth above; paler beneath, with many, parallel, whitish or purplish, hairy veins. The *spikes* are thick, with lanceolate, fringed, long-pointed *bracteas;* one or two of their lower whorls often very distant. *Flower-stalks* sometimes a little hairy in their upper part. *Calyx* as above described, its teeth sharp, mostly purple. *Corolla* purplish, smooth, longer than the *stamens*.—The flavour of the whole herb is pungent, highly aromatic, leaving a coolness in the mouth, like camphor, and finally a disagreeable bitterness. We have gathered, truly wild, in the romantic dale of Bonsall, near Matlock, the precise Pepper Mint of the gardens, in its highest perfection, with elongated spikes; which is of rare occurrence in a wild state.

12. M. *crispa*. Curled Mint. Linn. Sp. Pl. 805. Berg. Mat. Med. 513. Ehrh. Pl. Off. 206. Riv. Monop. Irr. t. 50. (M. n. 230; Hall. Hist. v. 1. 100. M. crispa danica; Moris. sect. 11. t. 6. f. 5.)—Leaves sessile, heart-shaped, wavy, strongly toothed. Spikes capitate, blunt. Teeth of the calyx, and top of the flower-stalks slightly hairy.—Native of Siberia, according to Linnæus. Haller considered it as merely the outcast of gardens in Switzerland. With us it is only seen in a cultivated state, and that but rarely. The stems are three or four feet high, rather bluntly quadrangular, clothed with a few hairs curved downward, but little branched, leafy. *Leaves* numerous, nearly or quite sessile, heart-shaped, somewhat pointed, short and very broad, wavy and plaited, with very strong, twisted, crowded, acute, marginal teeth; nearly smooth above; slightly hairy beneath; the veins all radiating, as it were, from the lower part of the mid-rib. *Spikes* usually short, capitate, and very blunt; sometimes more elongated and tapering, as in the plate of Rivinus. *Bracteas* broad, recurved. *Flower-stalks* smooth, except a roughness, or slight hairiness, at the very summit. *Calyx* ribbed, tumid at the base, contracted a little higher up, smooth, except a few marginal hairs on the long and sharp teeth. *Corolla* smooth, purplish, rather longer than the stamens.—This is most akin in foliage to the exotic variety of *M. viridis* above-mentioned; nor do their *calyces* or *flower-stalks* much differ. We are by no means certain that it ought not likewise to be considered as a form of *viridis*. The original *crispa* of Sp. Pl. ed. 1, is no other than *rotundifolia*, which is also the *crispa* of Jacquin. As the specimen came from Siberia, it seems to have caused Linnæus to attribute that *habitat* to the species, which thus proves erroneous. Roth says the true *crispa*, which by his description he seems to understand, is found in watery places near Rübeland in Hercynia.—*M. dentata*, Willd. n. 15, seems by his own suggestion, as well as the description, to be a whorled variety of this.

13. M. *odorata*. Bergamot Mint. Sm. Fl. Brit. n. 5. Engl. Bot. t. 1025. Sole Menth. t. 9. (M. citrata; Ehrh. Beitr. fasc. 7. 150. Willd. n. 13. M. rubra; Mill. Dict. ed. 8. n. 9, with a false description, as mentioned under *M. viridis*.)—Leaves stalked, heart-shaped, naked on both sides. Spikes capitate, very blunt. Calyx and flower-stalks perfectly smooth.—Native of watery places in Cheshire and North Wales. *Sole*. Willdenow thinks it may possibly be wild in the Palatinate. In gardens it is often preserved, for the sake of its fine scent, resembling that of the Bergamot Orange, being more powerful than *Monarda didyma*. The whole *herb* often assumes a dark purplish hue, in which it agrees with *piperita;* but it differs from all the Mints known to us, at least all that otherwise approach it, in being perfectly destitute of hairiness throughout. The *leaves* are broad, short, and heart-shaped. *Inflorescence* more truly capitate than in any variety of the Pepper Mint, and agreeing with the capitate state of *M. hirsuta*, n. 14, from which the uniformly smooth *flower-stalks* and *calyx* always keep it very distinct.

14. M. *hirsuta*. Hairy Mint. Sm. Fl. Brit. 616.

α, with short round terminal heads. M. hirsuta; Linn. Mant. 81. Sm. Tr. of L. Soc. v. 5. 193. Hudſ. ed. 1. 223. Engl. Bot. t. 447. (M. aquatica; Hudſ. 252, α and β. Sole Menth. t. 10, 11. M. aquatica, sive Sisymbrium; Raii Syn. 233. Ger. em. 684. M. palustris spicata; Riv. Monop. Irr. t. 49. M. Sisymbrium dicta hirsuta, glomerulis ac foliis minoribus ac rotundioribus; Dill. in Raii Syn. 233. t. 10. f. 1. M. piperita; Linn. Sp. Pl. 805. Berg. Mat. Med. 516. Origanum vulgare; Fl. Dan. t. 638!)

β, with a more elongated terminal head, or blunt spike. M. hirsuta δ and ε. Fl. Brit. 617. (M. palustris; Sole Menth. t. 6. M. paludosa; ibid. t. 22. Menthastri aquatici genus hirsutum, spicâ latiore; Bauh. Hist. v. 3. p. 2. 222. Raii Syn. 234. M. minus; Ger. em. 685.)

γ, with

γ, with whorled flowers. M. hirsuta ζ—θ; Fl. Brit. 617. (M. sativa; Linn. Sp. Pl. 805, excluding the synonyms. Sm. Tr. of L. Soc. v. 5. 199. Engl. Bot. t. 448. M. rivalis β, γ, and δ; Sole Menth. 45.)

Leaves stalked, ovate. Flowers capitate or whorled. Calyx entirely clothed with hairs curved upwards. Flower-stalks rough with deflexed hairs.—Common in watery places throughout Europe. This is the most variable species of the whole. It is often purplish; always more or less hairy, and in general remarkably so; the hairs of the *stem, branches*, and *flower-stalks* all curved downward, those of the *foot-stalks, leaves*, and especially those which clothe the *calyx*, all turned forward or upward. The direction of the pubescence never varies, though its quantity is extremely variable. We have a wild specimen, which to the naked eye looks nearly as smooth as the *odorata* last described, but which is, indeed, minutely hairy, especially the *calyx* and *stalks*. The root that bore this, being transplanted into a neighbouring garden, produced, the following year, a plant as hairy as any variety we have seen. The smell of the present species is likewise changeable. In general it is pungent and aromatic, much like Spear Mint, but sometimes acquires the flavour of Pepper Mint, or of Camphor, and occasionally a very sweet odour, like Frankincense Thyme, very lasting in specimens seventy years old, and which is now and then found in the, usually fetid, *M. arvensis*. The *stems* are upright, mostly branched, in the manner of *M. odorata*. *Leaves* stalked, ovate, rather acute, but sometimes blunt, serrated, very variable in size; their veins strong and parallel. *Flowers* purplish; in the first variety, α, capitate, like those of *odorata*, with one or two dense, distant, stalked, axillary whorls below; in β, so many whorls terminate the stem or branches as to form a bluntish spike, still accompanied by a distant whorl, or rather a pair of stalked axillary heads, underneath; this has been made a species by most authors, but it has all the essential characters of α, into which we have observed it to change, even in a wild state, according to changes in the moisture of the soil; this is the *palustris* of Sole, t. 6; his *paludosa*, t. 22, has the whorls sessile, and more numerous, so as more nearly to resemble a properly whorled mint, which plants of this kind, from Mr. Sole, have completely become in our garden; in γ, which like α varies in size, hairiness, colour, and flavour, the inflorescence is entirely whorled throughout. It is not without repeated observations on these plants in their wild state, and long cultivation of them in two different gardens, one wet, the other dry, that we have been decided in considering these different forms of inflorescence, in the *M. hirsuta*, as constituting no specific distinction. We have indeed specimens which shew the change from α to γ. This is a point nevertheless which theoretical botanists find difficult to allow, and which nothing but great experience can establish. See a similar instance mentioned at the end of our 12th species.

15. M. *acutifolia*. Fragrant Sharp-leaved Mint. Fl. Brit. n. 7. Engl. Bot. t. 2415. (M. verticillata; Mill. Dict. ed. 8. n. 17.)—Flowers whorled. Leaves ovato-lanceolate, tapering at each end. Calyx hairy all over. Hairs of the flower-stalks spreading.—The only specimen we have ever seen, was gathered by Rand, at the side of the river Medway, in Kent. Miller says the plant grew between Rochester and Chatham, where Mr. Sowerby has sought it in vain. We doubt its being distinct from *M. hirsuta*, but the much more spreading hairs of the *flower-stalks*, first induced us to think it more than a variety. The very sweet scent, like frankincense thyme, agrees with a variety above-mentioned of *hirsuta*, nor perhaps can the tapering bases of the *leaves* be thought of more importance, as the foliage of the latter species is acknowledged to vary much. The *whorls* are all quite sessile. *Calyx* clothed with ascending hairs, especially at the base, by which this plant is essentially distinguished from *rubra*, n. 17, while the hairy *flower-stalks* distinguish it from the following.

16. M. *canadensis*. Canadian Mint. Linn. Sp. Pl. 806. Ait. Hort. Kew. n. 13.—Flowers whorled. Leaves ovato-lanceolate, tapering at each end. Footstalks twice as long as the whorls. Calyx hairy all over. Flower-stalks quite smooth.—Gathered in Canada by Kalm. It was sent in 1801, by the late Mr. Masson, to Kew garden, where it lives in the open air, flowering in July. No figure of this species has yet appeared. It is more nearly allied to our *acutifolia*, than to the *arvensis*, with which Linnæus compares it. The long slender *footstalks*, sharply serrated and more lanceolate *leaves*, and the perfectly smooth and naked *flower-stalks*, are its discriminating characters. The *calyx* is hairy all over, with more erect hairs than in *arvensis*. The *whorls* are accompanied by long linear *bracteas*.

This should seem to be *M. borealis* of Michaux, Boreal-Amer. v. 2. 2; while his *tenuis* appears to be our small American variety of *viridis*, mentioned under that species; but having seen no specimens, we decline a positive reference to his work.

17. M. *rubra*. Tall Red Mint. Tr. of L. Soc. v. 5. 205. Engl. Bot. t. 1413. (M. sativa; Sole Menth. t. 21. M. verticillata; Raii Syn. 232. Riv. Monop. Irr. t. 48. f. 1. M. sativa rubra; Ger. em. 680. M. pratensis; Sole Menth. t. 17. (See Tr. of L. Soc. v. 5. 275.)—Flowers whorled. Leaves ovate. Stem upright, zigzag. Flower-stalks and lower part of the calyx very smooth; teeth hairy. Found about ditches, wet hedges, and the borders of rivers, not unfrequently, in England. Foreign writers seem unacquainted with this, which is the tallest and handsomest of our Mints, rising to the height of four, five, or six feet, with a red, wavy, usually smooth *stem*, bearing few and short branches. *Leaves* ovate, stalked, of a dark shining green, often very broad, with strong serratures; the upper ones small and short. *Whorls* numerous, stalked, of many large purplish-red *flowers*, with linear fringed *bracteas*. *Calyx* tubular, dotted with numerous resinous points, quite smooth, like the *flower-stalks*, except the teeth, which are always more or less furnished with upright hairs. The whole plant has a strong aromatic scent, especially in a dry soil. We have seen it kept in country gardens, and called Heart Mint, from its supposed cordial qualities. The Rev. Mr. Williams has observed this species in Shropshire, acquiring the peculiar scent of *M. arvensis*, of which we know no other instance.

18. M. *gentilis*. Bushy Red Mint. Linn. Sp. Pl. 805. Engl. Bot. t. 2118. (M. rubra; Sole Menth. t. 18. M. rivalis α; ibid. t. 20. M. variegata; ibid. t. 19. M. arvensis verticillata versicolor; Moris. sect. 11. t. 7. f. 5.)—Flowers whorled. Leaves ovate. Stem very much branched and spreading. Flower-stalks and base of the calyx smooth.—In watery waste places, but not common. We have it from North Wales, Shropshire, and Somersetshire. Linnæus says it grows in the south of Europe, and Dr. Sibthorp found what he took for this species, and judged to be the Ἡδύοσμος ἄγριος of Dioscorides, frequent among stubble in Greece, at the end of autumn; but there being no specimen in his herbarium, we cannot be certain of what he intended. This differs widely from the last in having a low, bushy, much-branched *stem*. The whole plant is rather hairy, and on a dry soil pleasantly aromatic. *Leaves* paler, less shining, and more elongated than in *rubra*, as well as more uniform in shape; their veins whitish underneath.

neath. *Whorls* not quite fessile. *Bracteas* lanceolate, various in size. *Flower-stalks* round, purple, for the most part very smooth. Upper part of the *calyx* more or less rough, with ascending hairs; base smooth; the whole sprinkled with resinous dots. *Corolla* pale purple, generally as long as the stamens.—The variety with blotches of yellow on the *leaves*, (Sole's t. 10, figured also in Morison,) when cultivated in a dry gravelly soil, is much improved in scent, and undergoes other changes; the *whorls* often become elevated on long leafy stalks, and the *flower-stalks* rough with deflexed hairs.

19. M. *gracilis*. Narrow-leaved Mint. Sole Menth. t. 16. Fl. Brit. n. 10. (M. gentilis; Engl Bot. t. 449. Sole Menth. t. 15. M. hortensis verticillata, ocymi odore; Moris. sect. 11. t. 7. f. 1.)—Flowers whorled. Leaves lanceolate, nearly sessile. Stem much branched, erect. Flower-stalks and base of the calyx very smooth.—On commons and waste ground, chiefly in watery places. The variety smelling like Basil, *gentilis* of Sole, is said by that author to be "frequent in ditches and waste places, near towns and villages, but scarcely wild." We have seen it in gardens only, where it is sometimes kept for its scent, resembling Basil, or the perfume of the Muscat Grape; but this favour is not so constant in the living plant, nor so permanent in the dry one, as many others met with in this genus. The ordinary *M. gracilis* has the strong lasting scent of *viridis*, not of the finest kind. The whole *herb* is a little hairy. *Stem* erect, twelve or eighteen inches high, much branched about the middle, leafy, rough, and reddish. *Leaves* uniform, lanceolate, acute, sharply serrated, tapering much at the base, but hardly stalked, bright green, slightly clothed with short hairs. *Whorls* generally sessile, with lanceolate hairy *bracteas*. *Flower-stalks* round, purple, uniformly and perfectly smooth. *Calyx* tubular, somewhat bell-shaped, purple, with resinous dots; very smooth and naked at the base; furrowed upwards, and clothed towards the top, especially its taper-teeth, with white upright hairs. *Corolla* purplish, bearded at the extremity, longer than the *stamens*.—The Basil-scented variety has deflexed *leaves*; the lower ones ovate; the floral ones often so small, that it assumes the aspect of a spiked mint. Had we not found it by culture extremely variable in these characters, while the *flowers* constantly agree with the true *gracilis*, we might have been tempted to consider this variety a distinct species.

20. M. *arvensis*. Corn Mint. Linn. Sp. Pl. 806. Hudf. 253. Fl. Brit. n. 11. Engl. Bot. t. 2119 Sole Menth. t. 12. Ehrh. Pl. Off. 416. Fl. Dan. t. 512. (M. arvensis verticillata procumbens; Moris. sect. 11. t. 7. f. 5. Calamintha aquatica; Ger. em. 684. M. præcox; Sole Menth. t. 13.)—Flowers whorled. Leaves ovate. Stem much branched, diffuse. Calyx bell-shaped, clothed all over with horizontal hairs.—Frequent in corn-fields where water stagnates in winter, especially on a sandy or gravelly soil. It is often a troublesome weed, because of the widely-creeping nature of the *root*, and its turgid fleshy shoots, well calculated to retain life in a soil that fluctuates as to humidity. The *stems* are mostly diffuse, and much branched. *Leaves* ovate, inclining to elliptical, obtuse, pale, clothed with rather rigid prominent hairs. *Flower-stalks* shortish, round, generally smooth, sometimes furnished with a few spreading, or slightly deflexed, hairs. *Calyx* shorter, more bell-shaped, and more broadly toothed than in any of the foregoing, and essentially characterised by being clothed all over with horizontally spreading hairs. *Flowers* reddish-lilac, externally hairy.

This species is readily known by its peculiar scent, justly compared to that of blue mouldy cheese, and which Haller says he could not endure. The dried specimens strongly retain it. The neat, elliptical, smoother *leaves* of Mr. Sole's *præcox*, and its earlier time of flowering, indicate somewhat of a specific difference, but culture and repeated observations have not confirmed it. *M. austriaca*, Jacq. Austr. t. 530. Willd. n. 18, is with great probability suspected by the latter author to be a variety of *arvensis*. Mr. Winch has sent us from Northumberland an ascending unbranched specimen of *arvensis*, very like Jacquin's figure; but having seen no Austrian specimen, we can decide nothing on the subject. The hairs of the *calyx* and *flower-stalks*, which nobody has properly described or figured, must settle the matter in dispute. Jacquin's plate bears a great resemblance to the *præcox*. A variety of *arvensis*, with the flavour of Basil, is the *gentilis* of Mill. Dict. ed. 8. n. 15.

21. M. *agrestis*. Rugged Field Mint. Sole Menth. t. 14. Engl. Bot. t. 2120. (M. arvensis *β*; Fl. Brit. 624. Tr. of Linn. Soc. v. 5. 213; 216.)—Flowers whorled. Leaves somewhat heart-shaped, strongly serrated, rugose. Stem erect. Calyx bell-shaped, clothed all over with horizontal hairs.—Observed by Mr. Sole in corn-fields and neglected gardens in Somersetshire. Mr. Borrer finds it very common in Sussex. We have been induced, in the 30th vol. of Engl. Bot. to agree with Mr. Sole in separating this plant from *arvensis*, on account of its upright *stem*, and roundish-heart-shaped, rugged, dark, strongly serrated *leaves*, which give it a peculiarly coarse and harsh aspect; all which marks our cultivated and abundantly increasing specimens have now retained for thirteen years without the least variation. The parts of the *flower*, and the scent of the whole *herb*, accord entirely with the *arvensis*.

22. M. *Pulegium*. Common Penny-royal. Linn. Sp. Pl. 807. Woodv. Med. Bot. t. 171. Sole Menth. t. 23. Engl. Bot. t. 1026. (Pulegium; Fuchs. Hist. 198. Riv. Monop. Irr. t. 23. f. 1. Bruns. Herb. v. 1. 227. P. regium; Ger. em. 671.)—Flowers whorled. Leaves ovate. Stem prostrate. Flower-stalks downy. Calyx hairy all over, with fringed teeth.—Native of watery places in various parts of Europe. This is much smaller than any of the preceding, and is known by its prostrate *stems*; small, downy, stalked, ovate, reflexed *leaves*, sparingly serrated; and numerous dense whorls of purplish, sometimes white, *flowers*, without *bracteas*. The *flower-stalks* are always densely clothed with fine short prominent hairs or down. *Calyx* less densely clothed, either with hairs of the same length, or, as is most commonly the case, with longer and more bristly hairs, a little ascending: its teeth fringed with bristles; its mouth closed with hairs. *Corolla* twice the length of the calyx, very hairy externally, shorter than the *stamens*. The broadest segment of the *corolla* is decidedly cloven, as it ought to be in *Mentha*. Some botanists thought they found it otherwise, and on that ground were disposed to separate *Pulegium* as a genus.

The flavour of Penny-royal is peculiarly strong, resembling *Thymus Nepeta*, Fl. Brit., but not confined to these plants. Some *Cunilæ* and *Satureja* have the same scent.

Some old authors distinguished from this the Mentha aquatica, pulegium mas dicta; Tournef. Inst. 190. Pulegium latifolium alterum; Bauh. Pin. 222. P. mas; Ger. em. 671.—This is said to differ in having an erect stem. We have carefully examined a specimen in Sherard's herbarium, and have been inclined to make it a distinct species, the *leaves* being broad and nearly smooth, and the hairs of the *calyx* rather more long and bristly than in any British varieties of *Pulegium*. Still as we perceive gradations among the latter, we prefer leaving the matter as we find it, till living specimens fall in our way. About the following we have less doubt.

23. M.

23. M. *tomentosa*. Downy Penny-royal. (M. aquatica tomentosa minima; Tourn. Inst. 190. Pulegium tomentosum minimum; Bocc. Sic. 40. t. 41. f. 2.)—Flowers whorled. Leaves ovate, hairy. Stem ascending. Flower-stalks densely clothed with horizontal hairs. Calyx covered with long loosely-spreading hairs.—Native of Sicily. We have it from Algiers, sent by the late Monf. Brouffonet. Its appearance is altogether much more hairy or shaggy than any variety of *Pulegium;* the mouth of the *calyx* is entirely closed with wool rather than hair, and the hairy covering of the *flower-stalks* is remarkable for its great length and density. If these marks be accidental, we know no other instance of the kind among *Menthæ*, yet we confess them rather differences in degree, than in direction, of the pubescence.

24. M. *cervina*. Hyssop-leaved Mint. Linn. Sp. Pl. 807. Willd. n. 21. (M. n. 222; Hall. Hist. v. 1. 98. Pulegium angustifolium; Moris. sect. 11. t. 7. f. 7. Riv. Monop. Irr. t. 23. f. 2. Ger. em. 672.)—Flowers whorled. Bracteas palmate. Leaves linear. Calyx and flower-stalks smooth.—Native of the south of France. A most distinct and remarkable species. The whole *plant* is smooth, larger than *Pulegium*, with which it nearly agrees in flavour and qualities. *Stem* ascending, slightly quadrangular, not much branched. *Leaves* sessile, linear, keeled, nearly or quite entire; their under side copiously dotted. *Whorls* large, dense, many-flowered, each accompanied by a pair of broad, rigid, ribbed, palmate *bracteas*. *Calyx* tubular, ribbed, with short spinous teeth. *Corolla* twice as long as the calyx. *Stamens* prominent.

Two Linnæan species remain to be noticed. These are—*M. exigua;* Linn. Sp. Pl. 806 Sm. Plant. Ic. ex Herb. Linn. t. 38. This is shewn in Tr. of Linn. Soc. v. 3. 18, to be the same plant as *Cunila pulegioides* of Linnæus, and is therefore struck out of the present genus.

M. *perilloides*. Linn. Syst. Veg. ed. 13. 445. (Ocymum frutescens; Linn. Sp. Pl. 832.)—This is indeed distinct from *Perilla ocymoides*, with which some have been disposed to confound it; but so little like a *Mentha*, that it does not concern our present subject; neither is the original specimen sufficient to determine its genus. S.

MENTHA *canariensis* and *plumosa*. See BYSTROPOGON.

MENTHA, in *Gardening*, comprehends plants of the hardy herbaceous perennial kind, of which the species cultivated are, the spear-mint (M. viridis); the round-leaved mint (M. rotundifolia); the curled mint (M. crispa); the pepper-mint (M. piperita); the red mint (M. gentilis); the penny-royal (M. pulegium); and the hyssop-leaved mint, or upright penny-royal (M. cervina.)

From the first kind not being so hot to the taste as peppermint, and having a more agreeable flavour than most of the other sorts, it is generally preferred for culinary and other purposes. The leaves and tops are used in spring salads, and eaten as sauce with lamb, and, when dried, in soups, &c.

There are several varieties of it, as, the broad-leafed; the narrow-leafed; the curled-leafed; the variegated-leafed; the silver-striped-leafed; and the gold-striped-leafed.

The fourth species, in its external appearance, corresponds with the first sort, for which it may easily be mistaken; but in that the stem is taller, the leaves have scarcely any petioles, and are narrower in proportion to their length, the spikes are longer and composed of more whorls.

In the fifth sort there is a variety with the scent of basil; the orange-scented mint; the gold-striped orange mint; the yellow-orange mint; and the reddish-orange mint.

And the sixth species varies with a white flower, and with the stems erect, nearly a foot high: the leaves longer and narrower: the whorls of flowers much larger, the stamens longer than the corolla: this is Spanish penny-royal, which has almost superseded the other sort; the stems being more erect, it is easier to tie in bunches, and it comes earlier to flower, and has a brighter appearance,

In the seventh sort there is a variety with white flowers, growing taller than the common one with purple flowers, which is by some preferred to the sixth sort for medicinal use, and called Hart's penny-royal.

Method of Culture in the Mint Kind.—All these plants may be increased with facility by young offset plants or shoots, or by parting their roots, and planting them out in the spring, or by planting cuttings during any of the summer months in a moist soil. After the cuttings are planted, when the season is dry, they should be often watered until they have taken root; when they require no further care, but to be kept clean from weeds. The best method is to plant them in beds about four feet wide, allowing a path about two feet broad between them, to water, weed, and cut the plants; being set four or five inches or more distant in the rows, as the plants spread much at their roots; on which account the beds should not stand longer than three years before planting them again, as by that time the roots become so closely matted, as to rot and decay each other when they are suffered to stand longer.

With regard to the general culture it is that of clearing them from weeds in spring and summer, cutting down all the remaining stalks annually in autumn; removing all weeds; digging the alleys, and spreading a little of the earth over the beds. Plantations thus formed will afford several cuttings every summer, when only wanted young for use, for culinary purposes; but when for drying to keep in winter, or green for distilling or medicinal use, the plants should generally be suffered to stand until nearly full grown, and they are just coming into flower; which being then cut down close, the roots send up another crop fit for cutting again in the beginning of autumn, or towards Michaelmas; each general cutting being always made as close to the ground as it possibly can be done.

Method of forcing Mint on Hot-beds.—Where it is much wanted for salads in the winter and early spring seasons, a hot-bed should be made for this purpose, any time after November till the spring, about two feet thick of dung, covering it with garden frames and glasses, or with mats on arched sticks, which should then be earthed over with rich mould, six inches thick; when a quantity of roots should be taken up from a bed and planted pretty close together upon the surface of the bed, moulding them over an inch deep with fine earth, putting on the lights, or other coverings, keeping them close in the nights and in bad weather, but admitting fresh air in mild weather. The plants soon come up, when fresh air should be admitted in fine weather, and moderate waterings should be given, and they will soon be ready to have their young green tops gathered for use. When the plants are two or three inches high, they are ready for being cropped, after which they presently break out again, and fresh shoots rise from the bottom; so that the same bed furnishes fresh supplies a long time; two beds, made at different times, being generally sufficient for the whole winter use. In this way mint may be obtained young and green from the time that in the natural ground it goes off in autumn until it comes in again in the spring season.

Young mint shoots may also be procured by planting some roots thick in large pots, and placing them in a hot-house,

houſe, as they quickly ſhoot and furniſh plants of young green mint in ſuch ſituations.

Where this practice is much attended to, ſmall freſh plantations ſhould be made annually in the open ground for the purpoſe of furniſhing a ſufficiency of roots, proper for taking up at forcing time without diſturbing thoſe of the principal crops.

Method of Culture in the Pennyroyal Kinds.—Theſe may be increaſed in the ſame manner as above, and alſo by their creeping ſtems, which ſhould be cut off and planted out in freſh beds, allowing at leaſt a foot diſtance every way. The young ſhoots planted in the ſpring in the ſame way alſo take root like the other ſorts. The proper time for this work is in the early autumn, that the plants may be well rooted before winter.

It is found that in this way the plants are much ſtronger, and produce larger crops than when planted out in the ſpring. When the roots remain ſo cloſe as is generally the caſe, they are apt to rot in the winter ſeaſon. They ſucceed beſt in a moiſt ſtrong ſoil.

It may be noticed that ſome of the ſpecies and varieties may be introduced in the borders and other parts of pleaſure grounds, for ornament and variety with good effect.

Mentha, in the *Materia Medica*. Several ſpecies of this genus have ſome claims on our notice under this head. The *Mentha piperita*, or "pepper-mint," has a more penetrating ſmell than any of the other mints, and a much ſtronger and warmer taſte, pungent like pepper, ſinking as it were into the tongue, and followed by a ſenſation of coldneſs. By maceration, or infuſion, it readily and ſtrongly impregnates both water and ſpirit with its virtue. On diſtillation with water, it yields a conſiderable quantity of eſſential oil of a pale greeniſh-yellow colour, growing of a darker colour by age, very light, ſubtile, poſſeſſing in a high degree the ſpecific ſmell and penetrating pungency of pepper-mint. According to Dr. Cullen, rectification is particularly neceſſary and proper for this eſſential oil. What has been called eſſence of pepper-mint is, in his opinion, no other than the rectified oil, diſſolved in ſpirit of wine. Rectified ſpirit, drawn with a gentle heat from the tincture made in that menſtruum, brings over little of the virtue of the herb, nearly all its pungency and warmth remaining concentrated in the extract. This plant, it is obſerved, yields camphor. Its ſtomachic, antiſpaſmodic, and carminative qualities render it uſeful in flatulent colics, hyſterical affections, retchings, and other dyſpeptic ſymptoms, acting as a cordial, and often producing immediate relief. Its officinal preparations are an eſſential oil, a ſimple water, and a ſpirit. The water is prepared by pouring on, *e.g.* a pound and half of pepper-mint, ſo much water, that, after the diſtillation, a ſufficiency may remain to prevent empyreuma; and diſtilling over a gallon. The ſpirit of pepper-mint is obtained by macerating, for 24 hours, a pound and half of pepper-mint dried in a gallon of proof ſpirit, with water ſufficient to prevent empyreuma, and diſtilling a gallon by a gentle fire.

Mentha viridis, or *ſativa*, "ſpear-mint," is not ſo warm to the taſte as pepper-mint, but having a more agreeable flavour, it is preferred for culinary uſes, and more generally cultivated in our gardens. Many virtues are aſcribed by the ancients to mint, but the particular ſpecies is not aſcertained. This, however, is of no great importance in a medical view, as the virtues of all reſide in the aromatic flavour, which is common to the whole genus. On drying, the leaves loſe about three-fourths of their weight, without ſuffering much loſs of their ſmell or taſte; nor is the ſmell ſoon diſſipated by moderate warmth, or impaired on keeping. Cold water, by maceration for ſix or eight hours on the dry herb, and warm water in a ſhorter time, become richly impregnated with its flavour. By diſtillation, a pound and a half of the dry leaves communicate a ſtrong impregnation to a gallon of water: the diſtilled water proves rather more elegant, if drawn from the freſh plant in the proportion of ten pints from three pounds. Along with the aqueous fluid an eſſential oil diſtils, of a pale yellowiſh colour, changing to a red, in quantity near one ounce from ten pounds of the freſh herb in flower, ſmelling and taſting ſtrongly of the mint, but ſomewhat leſs agreeable than the herb itſelf. Dry mint, digeſted in rectified ſpirit, either in the cold or with a gentle warmth, gives out readily its peculiar taſte and ſmell, without imparting the groſſer and more ungrateful matter, though the digeſtion be long continued. The tincture appears by day-light of a fine dark green, by candle-light of a dark red colour: a tincture extracted from the remaining mint by freſh ſpirit, appears in both lights green: the colour of both tinctures changes, in keeping, to a brown. On gentle diſtillation, with proof ſpirit, the ſpirituous portion which riſes at firſt diſcovers little flavour of the mint; but as ſoon as the watery part begins to diſtil, the virtues of the mint come over plentifully with it. Hence the ſpiritus menthæ ſativæ, P. L., which is prepared by drawing off a gallon of proof ſpirit from a pound and a half of the dried plant, proves ſtrongly impregnated with the mint.

To ſpear-mint are to be aſcribed the ſame medicinal qualities which we have noticed of pepper-mint; but the different preparations of the former, though more pleaſant, are perhaps leſs efficacious. It contains much eſſential oil, but of an odour ſomewhat leſs agreeable than that of lavender or marjoram. It is therefore leſs employed as a cephalic; but it acts very powerfully on the parts to which it is immediately applied, and therefore conſiderably on the ſtomach, invigorating all its functions. It acts eſpecially as an antiſpaſmodic, and therefore relieves pains and cholic depending upon ſpaſm. It will alſo ſtop vomiting, depending upon ſuch a cauſe; but there are many caſes of vomiting in which it is of no ſervice: and in theſe caſes, anywiſe depending upon inflammatory irritation in the ſtomach itſelf, or in other parts of the body, it aggravates the diſeaſe, and increaſes the vomiting. Practitioners have thought, and we think juſtly, that the infuſion of mint in warm water agrees better with the ſtomach than the diſtilled water, which is often ſomewhat empyreumatic.

Lewis obſerves, that it is ſaid by ſome to prevent the coagulation of milk; and hence it has been recommended to be uſed along with milk diets, and even in cataplaſms and fomentations for reſolving coagulated milk in the breaſts. Upon experiment, the curd of milk, digeſted in a ſtrong infuſion of mint, could not be perceived to be any otherwiſe affected than by common water; but milk, in which mint leaves were ſet to macerate, did not coagulate near ſo ſoon as an equal quantity of the ſame milk kept by itſelf.

The officinal preparations of ſpear-mint are an eſſential oil, a conſerve, a ſimple water, and a ſpirit. Lewis M. M. Cullen M. M. Woodville Med. Bot.

The ſpear-mint water, aqua menthæ viridis of the London Pharmacopeia, is prepared by pouring on a pound and half of ſpear-mint ſo much water, that, after the diſtillation, enough may remain to prevent empyreuma; and diſtilling over a gallon. The ſpirit, ſpiritus menthæ viridis, is obtained by macerating, for 24 hours, a pound and half of dried ſpear-mint in a gallon of proof ſpirit, with water ſufficient to prevent empyreuma, and diſtilling a gallon by a gentle fire.

Mentha Pulegium, "Penny-royal mint," has a warm pungent flavour, somewhat similar to mint, but more acrid, and less agreeable both in smell and taste. Its active principle is an essential oil, of a more volatile nature than that of mint, coming over hastily with water at the beginning of the distillation, and rising also in great part with highly-rectified spirit; in taste very pungent, and of a strong smell; when newly drawn, of a yellowish colour, with a cast of green; by age turning brownish.

The pulegium certainly possesses the general properties of the other mints: it is supposed, however, to be of less efficacy as a stomachic, but more useful as a carminative and emmenagogue, and is more commonly employed in hysterical affections. We are told by Boyle, and others, that it has been successfully used in the hooping-cough; but the chief purpose to which it has long been administered is promoting the uterine evacuation. With this intention, Haller recommends an infusion of the herb with steel, in white wine, which he never knew to fail of success. However, in the opinion of Dr. Cullen, mint is in every respect a more effectual remedy than penny-royal; and nothing but the neglect of all attempts to establish principles could have made physicians think of this as a peculiar medicine different from the other species: and conformably to this remark, it may be observed, that this plant is less frequently used now than formerly.

Its officinal preparations are a simple water, a spirit, and an essential oil. Lewis M. M. Cullen M. M. Woodville Med. Bot.

Aqua pulegii, "Penny-royal water," is prepared by pouring on a pound and half of penny-royal so much water, that, after distillation, enough may remain to prevent empyreuma, and distilling over a gallon. The "spirit of penny-royal" is obtained by macerating, for 24 hours, a pound and half of dried penny-royal in a gallon of proof spirit, with water sufficient to prevent empyreuma, and distilling a gallon by a gentle fire. The water which distils over with the oils of pepper-mint, spear-mint, and penny-royal, is to be kept for use. Lond. Pharmac. 1809.

MENTI Levator, in *Anatomy*, a small muscle in the chin. It is described with the muscles of the lower lip, in the article Deglutition.

MENTOLE, in *Geography*, a town of the island of Ceylon, on the west coast; 80 miles W.N.W. of Trincomaly. N. lat. 9° 1′. E. long. 80° 3′.

MENTON, a town of France, in the department of the Maritime Alps, and chief place of a canton, in the district of Monaco; 6 miles N.E. of Monaco. The place contains 3289, and the canton 4383 inhabitants, on a territory of 60 kilometres, in 4 communes.

MENTOS, a town of Louisiana, on the Akansas; 150 miles S.W. of New Madrid. N. lat. 35° 27′. W. long. 92° 40′.

MENTUM, in *Anatomy*, the lower part of the face, beneath the mouth; which we otherwise distinguish by the name of *chin*.

MENTZ, or Mayence, *Archbishopric of*, in *Geography*, formerly an electoral principality of Germany, in which, besides corn, are breeds of cattle, fine garden fruits, and excellent wines, particularly those Rhenish wines that are furnished by the Rheingau: good salt is also manufactured here, and it has here and there iron mines. In the Mentz portion of the Berg-Strazza is found plenty of almonds, chesnuts, and filberds. The lower part of the Eichsfeld yields corn in sufficient abundance, together with large quantities of flax and tobacco. The principal rivers are the Rhine, the Maine, the Jaxt, and the Lahn. In the whole of the electoral countries of Mentz, comprehended within this circle, were 41 cities and 21 boroughs. Eichsfeld is now annexed to the kingdom of Westphalia. In the upper Eichsfeld are manufactures of serge and linen; and in the lower, tobacco and flax are cultivated. In the archbishopric are some woollen and other manufactures; and a considerable trade is carried on in wines. From Berg-Strazza are exported almonds, chesnuts, nuts, and nut-wood. The countries lying on the Rhine and on the Maine have, ever since the Reformation, been subject to the elector of Mentz, and maintained their attachment to the Roman Catholic faith. It was in the year 751 that the bishopric of Mentz was fully established as an archbishopric, which was first administered by S. Boniface; and with the archbishopric, the first in Germany, the dignity of elector was inseparably connected. In 1802, at the settlement of the indemnities, in consequence of the ascendency gained by the French in Germany, all that part of the diocese which lay on the right of the Maine, was given to the prince of Nassau-Usingen, except the bailiwick of Aschaffenburg. It was then determined that the electoral title should from that time be elector of Aschaffenburg, and count of Wetzlar; that he should still continue arch-chancellor of the empire, and hold his office at Ratisbon, with some abbies, and other indemnities, so as to yield an annual revenue of a million of florins. His jurisdiction, as metropolitan of the German church, was to extend all over Germany, except the Prussian states.

Mentz, or *Mayence*, formerly capital of the above-mentioned electorate and archbishopric of Germany, but by the treaty of Campo Formio, 1797, a city of France, chief place of a district, and capital of the department of Mont-Tonnerre, situated at the conflux of the Rhine and Maine; bearing in Latin the appellation of "Moguntium." It was considered as a barrier fortress of the empire. The city is large and populous, but consists, for the most part, of narrow streets and old-fashioned houses, intermixed with some fine buildings, a considerable palace, and a magnificent cathedral. Before the revolution, it contained seven parish churches, six monasteries, and five nunneries, with a charter-house and two other nunneries near the city, and also six hospitals. The university was founded by Charlemagne in 800, and established in 1482 by the archbishop Diether. It has undergone many revolutions, and frequently changed its masters, until in 1792 it was taken by the French; but in the following year it was retaken. By the peace between the emperor and the French it was surrendered to the latter, who took possession of it. The number of inhabitants is reckoned at 21,400, and those of its canton 21,615, in two communes. N. lat. 49° 58′. E. long. 8° 14′.

MENTZELIA, in *Botany*, named by Plumier in honour of Dr. Christian Mentzel, Counsellor and Physician to the Elector of Brandenburg, who published, in 1682, in folio, an Index of the names of plants in various languages, accompanied by a small catalogue of rare plants, with plates. He wrote also some papers in the Ephemerides Acad. Nat. Curios. on geological subjects, and died in 1701, aged 79. Plum. Gen. 40. Linn. Gen. 270. Schreb. 360. Willd. Sp. Pl. v. 2. 1175. Mart. Mill. Dict. v. 3. Jacq. Amer. 164. Ait. Hort. Kew. ed. 2. v. 3. 302. Juss. 321. Lamarck Illustr. t. 425.—Class and order, *Polyandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Onagræ*, Juss.

Gen. Ch. *Cal.* Perianth superior, spreading, deciduous, of five, lanceolate, concave, pointed leaves. *Cor.* Petals five, obovate, pointed, spreading, a little longer than the calyx. *Stam.* Filaments numerous (about thirty), the length of the calyx, erect, the outer ones membranous in the upper part; anthers roundish. *Pist.* Germen inferior,

 cylindrical,

cylindrical, long; ſtyle thread-ſhaped, as long as the ſtamens; ſtigma ſimple, obtuſe. *Peric.* Capſule cylindrical, long, of one cell, three-valved at top. *Seeds* about ſix, oblong, angulated.

Eſſ. Ch. Calyx of five leaves. Petals five. Capſule inferior, cylindrical, many-ſeeded.

1. M. *aſpera.* Linn. Sp. Pl. 735. (M. foliis et fructibus aſperis; Plum. Ic. 167. t. 174. f. 1.)—Stem branched. Flowers axillary. Petals notched, obtuſe.—A native of South America, and the Weſt Indies, very common among the buſhes in all the dry ſavannahs about Kingſton, Jamaica. It flowers in the gardens during July and Auguſt. *Root* annual. Whole herb clothed with rigid, partly hooked briſtles. *Stem* round, branched, leafy. *Leaves* on longiſh ſtalks, oblong, ſomewhat haſtate, acute, unequally and coarſely ſerrated *Flowers* axillary, ſolitary, nearly ſeſſile, yellow. The germen and calyx very briſtly.

2. M. *hiſpida.* Willd. n. 2. (M. aſpera; Cavan. Ic. v. 1. 51. t. 70.)—Stem forked. Flowers ſolitary, at the forks of the ſtem. Petals entire, acutely pointed.—A native of Mexico. This differs from the laſt in having the *leaves* more ovate, *flowers* principally from the forks of the ſtem, with a much ſhorter and ovate *germen*, and longer leaves of the *calyx*. Willdenow alſo points out the above difference of the petals.

This genus is very nearly allied in habit as well as character to Loosa (ſee that article); indeed ſo much are they alike, that we greatly ſuſpect they muſt be one genus, for which *Mentzelia*, being the oldeſt name, ought to remain, and the other ambiguous appellation would be happily ſuperſeded.

MENU, in *Biography*, is the name of a very celebrated law-giver among the Hindoos. Sir William Jones tranſlated his code from the original Sanſcrit; and it is in the hands of the public, under the title of "Inſtitutes of Hindoo Law, or the Ordinances of Menu." The work compriſes, in 12 chapters and 2685 verſes, the Indian ſyſtem of duties, religious and civil, and is held in the greateſt reverence by all claſſes of Hindoos; ſo much ſo, that ſhould a ſeries of Brahmans omit, for three generations, the reading of Menu, their ſacerdotal claſs would, as they aſſert, be forfeited. They muſt, however, explain it only to their pupils of the three higheſt claſſes: and to enſure a greater degree of reverence for its ſanctity, it is underſtood that a Brahman, duly pious, would not, on any conſideration, read it on a forbidden day of the moon, or until after the performance of certain ceremonies preſcribed in the code. The learned tranſlator, from internal evidence, aſcribes the date of the Inſtitutes, in their preſent form, to a period ſo far back as 880 years before Chriſt. Whether Menu, or Menus in the nominative, and Menos in an oblique caſe, was the ſame perſonage with Minos, he leaves others to determine; but he evidently inclines to that opinion, though, with his characteriſtic modeſty, he forbears any pointed expreſſion of it. He recogniſes a ſtrong reſemblance, though obſcured and faded by time, between the Menu of the Hindoos, with his divine bull, or the emblem of abſtract juſtice, and the Mneues of Egypt, with his companion or ſymbol Apis: and though he duly guards himſelf and his readers againſt the deluſions of etymological conjecture, he ſtates Minos and Mneues, or Mneuis, to be merely Greek terminations, and that the crude noun is compoſed of the ſame radical letters in Greek and Sanſcrit. "And if," he continues in his preface, "Minos, the ſon of Jupiter, whom the Cretans, from national vanity, might have made a native of their own iſland, was really the ſame perſon with Menu, the ſon of Brahma, we have the good fortune to reſtore, by means of Indian literature, the moſt celebrated ſyſtem of heathen juriſprudence." The fables of the Hindoos, as to the antiquity and origin of the laws of Menu, are in their uſual ſtyle of extravagance. They firmly believe them to have been promulgated in the beginning of time by Menu, ſon or grandſon of Brahma, or, in plain language, the firſt of created beings; and not the eldeſt only, but the holieſt of legiſlators.

Menu is highly honoured by name in the Véda itſelf, where it is declared, that "whatever Menu pronounced was a medicine for the ſoul itſelf;" and it is aſſerted by a high authority among the Hindoos, "that Menu held the firſt rank among legiſlators, becauſe he had expreſſed in his code the whole ſenſe of the Véda; that no code was approved, which contradicted Menu; that other ſaſtras, and treatiſes on grammar or logic, retained ſplendour only ſo long as Menu, who taught the way to juſt wealth, to virtue, and to final happineſs, was not ſeen in competition with them." It has been alſo authoritatively aſſerted, that "the *Véda*, with its *Angas*, or the ſix compoſitions deduced from it, the revealed ſyſtem of medicine, the *Puranas*, or ſacred hiſtories, and the code of Menu, were four works of ſupreme authority, which ought never to be ſhaken by arguments merely human." It is the general opinion of the Pandits, that Brahma taught his laws to Menu in 100,000 verſes, which Menu explained to the world in the very words of the book tranſlated by ſir William Jones. It was afterwards abridged to 12,000 verſes, and ſubſequently to 4000; but at preſent they conſiſt only of 2685 verſes. Of the numerous gloſſes or comments on Menu, that of Cullucá Bhatta is moſt highly commended by ſir William Jones, who has implicitly followed his text and interpretation.

The work, as preſented to the European reader by ſir William Jones, contains abundance of curious matter, extremely intereſting both to ſpeculative lawyers and to antiquaries; with many beauties, and with many blemiſhes, which cannot be juſtified or palliated. It is a ſyſtem of deſpotiſm and prieſtcraft, both indeed limited by law, but artfully conſpiring to give mutual ſupport, though with mutual checks: it abounds with ſtrange conceits in metaphyſics and natural philoſophy, with idle ſuperſtitions, and with a ſcheme of theology moſt obſcurely figurative, and conſequently liable to dangerous miſconceptions; with minute and childiſh formalities; with ceremonies generally abſurd, and often ridiculous. The puniſhments denounced are partial and fanciful; for ſome crimes dreadfully cruel, for others reprehenſibly ſlight: and the morals even, though rigid enough on the whole, are, in one or two inſtances, (as in the caſe of light oaths and of pious perjury,) unaccountably relaxed. Nevertheleſs, a ſpirit of ſublime devotion, of benevolence to mankind, and of amiable tenderneſs to all ſentient creatures, pervades the whole work. Some doubt, however, has been entertained with regard to the ſublimity of the devotion, and the amiable tenderneſs of feeling, aſcribed by ſir William Jones to this ſpecimen of the Hindoo writings; and it has been alleged, that the general character of the devotion of the Hindoos is that of a debaſing ſuperſtition, and that their tenderneſs for animals is chiefly ſuperſtition and weakneſs, derived from their doctrine of tranſmigration. The ſtyle of it has a certain auſtere majeſty that ſounds like the language of legiſlation, and extorts a reſpectful awe. The ſentiments of independence on all beings but God, and the harſh admonitions, even to kings, are truly noble. Whatever opinion, in ſhort, may be formed of Menu and his laws, in a country happily enlightened by ſound philoſophy and the only true revelation, it ought to be remembered that thoſe laws are actually revered as the word

word of the Moſt High, by nations of great importance to the political and commercial intereſts of Europe, and particularly by many millions of Hindoo ſubjects, whoſe well directed induſtry adds largely to the wealth of Britain, and who aſk no more in return than protection for their perſons and places of abode, juſtice in their temporal concerns, indulgence to the prejudices of their old religion, and the benefit of thoſe laws which they have been taught to believe ſacred, and which alone they can poſſibly comprehend. See Preface to ſir William Jones's tranſlation of the "Inſtitutes of Menu," in his Works, vol. vii. p. 75, &c. 8vo. (See GENTOOS.) For an extended account of its incomparable tranſlator, ſee our article JONES, *Sir* WILLIAM.

The Hindoos have, however, ſeven holy perſons diſtinguiſhed by the common denomination of Menu, whoſe names we ſhall preſently give; but the firſt and laſt only demand any particular notice. The name is derived from the Sanſcrit root *men,* or *man,* to underſtand or think; and it ſignifies, as all the Pandits agree, *intelligent,* particularly in the doctrines of the Veda, or a thinking being: hence *menes, mens,* and *mind,* alſo *man,* both in Gothic and Engliſh. If in the firſt Menu we recogniſe Adam, our great progenitor; ſo in the ſeventh we find Noah, the great reſtorer of our ſpecies. Here follow their names: 1. Swayambhuva, meaning the ſon of the Self-exiſtent; a name applied by different ſects to the peculiar object of their adoration. 2. Swarocheſha. 3. Uttama. 4. Tamaſa. 5. Raivata. 6. Chakſuſha. 7. Satyavrata. In the time of the laſt, the general deluge occurred. See MATSYAVATARA and ILA, alſo SWAYAMBHUVA and SATYAVRATA.

Although *ſeven* Menus are uſually referred to in Hindoo books, that preciſe number is not always given. In the tenth lecture of the Gita, (ſee MAHABARAT,) "the four Menus" are mentioned; and fourteen are ſpoken of in the Siva-purana. It ſeems, indeed, a generic term for *wiſdom.* Mr. Wilford (Af. Ref. vol. v.) thinks it likely that the ſeven Menus, the ſeven Brahmadicas, and the ſeven Riſhis, (ſee RISHI,) are the ſame, and make only ſo many individuals, firſt called Brahmadicas, or children of Brahma, created for the purpoſe of ſupplying the world with inhabitants. Having fulfilled this miſſion, they became ſovereigns, or Menus, who, when far advanced in years, withdrew from the world to ſolitary places to prepare for death; as, according to the Puranas, was the general practice of mankind in the early ages; and became Riſhis, or holy penitents, who, by their ſalutary counſels and the example of their auſterities, pointed out the paths of virtue and rectitude to mankind. There are ſtill much confuſion and contradiction in the accounts of the perſon and characters of theſe holy perſons, of whom many particulars occur in Moor's Hindoo Pantheon.

MENUET, Fr., MINUET, Engl., the name of a muſical movement in triple time of three crotchets or three quavers in a bar, which is the guide to a graceful dance in the ſloweſt time of any movement that is danced off the ſtage at public or private balls, ſince the louvre has totally loſt its favour.

The minuet, according to Broſſard, had its origin in Poitou. The melody of the minuet is uſually divided into two parts, or ſtrains, conſiſting of eight bars each, of which the firſt ends on the fifth of the key, and the ſecond on the key note.

There is ſo much dignity and grace in this dance, that it is to be lamented it has ceaſed to be a part of education, and to be diſcontinued at private balls and aſſemblies where elegance and decorum uſed to be obſerved. In learning the ſteps and figure of the minuet, other things neceſſary in poliſhed ſociety uſed to be taught; ſuch as the bow, the curtſey, the entrance into a room and departure from it with eaſe and grace, the preſenting to or receiving from a ſuperior; indeed the whole carriage of the perſon uſed to be regulated in learning the minuet, in a manner not, as we can diſcover, included in the Scotch ſtep or Iriſh lilt, the cotillon, or the waltz. Thoſe who never had the courage or intention to exhibit their perſons in a ball-room, public or private, have been diſcovered to have learned to dance by ſtanding ſtill or walking in the ſtreet, as a peaſant diſcovers himſelf to have been drilled in the ſame ſituations.

MENUF, or MENOUF, in *Geography,* a town of Egypt, and chief place of a diſtrict, ſeated near a canal, which was formerly navigable, but has ceaſed to be ſo in conſequence of a dyke raiſed for reſtraining the inundations of the Nile in that branch of it which runs to Damietta. The canal ſurrounds the walls of the town from S. to W. The houſes are mean and the ſtreets narrow and crooked; nor has it many remains of antiquity. In its vicinity are no gardens, ſo that it is ſupplied with fruit and vegetables from a diſtance; but the land is well cultivated and produces wheat, barley, maize, lentils and lupines. The cultivation of maize from ſeed-time to harveſt occupies 70 or 80 days. The animals employed in huſbandry are oxen, buffaloes, camels, aſſes, and a few horſes. Menuf, during the inundation, is ſurrounded with water, but it does not long continue. It is ſheltered from the S., and being open to the N. and N.W., it is kept moderately cool. The number of inhabitants is about 5000; 22 miles N.N.W. of Cairo.

MENUFIE, or MENOUFIE, the diſtrict of which Menuf is the capital, on the S. part of the Delta, between the E. and W. branches of the Nile.

MENUGAT, a town of Aſiatic Turkey, in the province of Caramania, on a river of the ſame name, which runs into the gulf of Satalia; 21 miles W. of Alanieh.

MENYANTHES, in *Botany,* according to Linnæus, is derived from μην, *a month,* and ανθος, *a flower,* becauſe the plant continues in bloſſom about that period of time. *M. trifoliata* is undoubtedly the μινυανθες of Theophraſtus and *Minyanthes* of Pliny, becauſe thoſe authors deſcribe it as having ternate leaves and ornamental flowers. Buckbean. Linn. Gen. 82. Schreb. 107. Willd. Sp. Pl. v. 1. 810. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 225. Prod. Fl. Græc. p. 1. 128. Ait. Hort. Kew. ed. 2. v. 1. 312. Tournef. t. 15. Juſſ. 98. Lamarck Illuſtr. t. 100. Gærtn. t. 114. Claſs and order, *Pentandria Monogynia.* Nat. Ord. *Preciæ,* Linn. *Lyſimachiæ,* Juſſ. *Gentianæ,* Ventenat.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, five-cleft, erect, permanent. *Cor.* of one petal, funnel-ſhaped; tube cylindrically funnel-ſhaped, ſhort; limb cloven below the middle into five, ſpreading, recurved, obtuſe, more or leſs hairy ſegments. *Stam.* Filaments five, awl-ſhaped, ſhort; anthers acute, cloven at the baſe, erect. *Piſt.* Germen ſuperior, conical; ſtyle cylindrical, exactly as long as the corolla; ſtigma cloven, compreſſed. *Peric.* Capſule ovate, enveloped by the calyx, of one cell. *Seeds* numerous, ovate, ſmall.

Eſſ. Ch. Corolla hairy. Stigma cloven. Capſule of one cell.

1. M. *nymphæoides.* Fringed Buckbean. Leſſer Yellow Water Lily. Linn. Sp. Pl. 207. Engl. Bot. t. 217. Fl. Dan. t. 339.—Leaves heart ſhaped, entire, waved. Corolla ciliated. Found occaſionally in rivers and lakes, though by no means ſo common a plant with us as in the ſtill canals of Holland. It flowers from June to Auguſt. *Root* perennial, long and ſtringy *Stems* very long, round, bearing leaves and flowers towards their ſummits. *Leaves* oppoſite, ſimple,

fimple, on ftalks, floating, heart-fhaped or roundifh, wavy, fmooth. *Flowers* axillary, crowded together, on ftalks, expanding at noon, of a golden colour, fringed at the margin. Dr. Smith obferves, that the leaves of this plant, like thofe of the *Nymphæa*, perfpire fo quickly as to become dry in a few hours, though at firft fo fucculent. Some authors have thought from the corolla being ciliated, not hairy, that *M. nymphæoides* fhould be referred to another genus. But as Juffieu, whofe authority upon fuch a point is very great, has not feparated this from *M. trifoliata*, and as *M. indica* and *ovata* feem to connect the two, we think with Dr. Smith they may fafely remain as they are.

2. M. *ovata*. Oval-leaved Buckbean. Linn. Suppl. 133. Willd. n. 2. (M. capenfis; Thunb. Prod. 34. Villarfia ovata; Vent. Choix de Plantes, t. 9.)—Leaves ovate, on long ftalks. Stem panicled. An aquatic of the Cape, flowering in May and June. Linnæus obferves that this fpecies has the habit of an *Alifma*, but the flower of a *Menyanthes*. *Root* fibrous. *Stems* few, about two feet high and the thicknefs of a quill, ftraight, cylindrical, fometimes naked and like ftraws, more frequently furnifhed with three or four leaves, fimple, fmooth, bright green. *Leaves* obtufe, generally quite entire, nerved, fmooth, of a bright green colour and bitter flavour. *Flowers* on ftalks, bracteated, of a fine yellow or citron colour, without fmell.

3. M. *indica*. Indian Buckbean. Linn. Sp. Pl. 207. Bot. Mag. t. 658.—Leaves heart-fhaped, fomewhat notched. Flowers on fimple ftalks. Corolla internally hairy. Native of the Cape, flowering nearly through the fummer. *Root* fibrous. *Stems* floating, branched. *Leaves* peltate, bright green on one fide, dark ruffet on the other. *Flowers* forming a lax umbel, placed on the ftem juft below the leaf, of a bright yellow colour, looking as if covered with filver froft.

4. M. *criftata*. Crefted Buckbean, or Antara-Jamara of the Telingas. Roxb. Coromandel. v. 2. 3. t. 105.—Leaves heart-fhaped, wavy. Flowers on fimple ftalks. Corolla with an elevated crefted rib.—A native of banks, or pools of frefh water, in the Eaft Indies, where it floats, often not reaching the bottom with its roots. Flowering time the wet and cold feafon.—*Roots* annual, fibrous. *Stems* numerous, much fpreading. *Leaves* on fhort ftalks, fmooth; green above with a purplifh tinge. *Flowers* in a loofe umbel, not hairy, of a pure white colour, about an inch in diameter. Rheede defcribes the laft fpecies as having ten ftamens. We fufpect the prefent, which has alfo ten, though five are imperfect, is what fir William Jones defcribed in his felect Indian plants, calling it *Cumuda*, or delight of the water, which feems to be a general name for beautiful aquatic flowers.

5. M. *exaltata*. Tall Buckbean. Soland. MSS. and Herb. Banks. Ait. Hort. Kew. ed. 2. v. 1. 312. Bot. Mag. t. 1029.—Leaves roundifh-heart-fhaped, fomewhat peltate, flightly crenate. *Stem* panicled. A native of New South Wales, where it was difcovered by fir Jofeph Banks. It flowers from November to February, being kept in a ciftern near the glafs in a bark-ftove. This is a larger plant than any of the preceding, with a tall, panicled, many-flowered *ftem*. The *leaves* are heart-fhaped, veiny and wavy. *Flowers* deep yellow, their petals toothed at the edge, and bearded on the upper fide at the bafe. Dr. Sims remarks that it is nearly allied to *M. ovata*, and fhould immediately precede that fpecies.

6. M. *trifoliata*. Common Buckbean, or Marfh Trefoil. Linn. Sp. Pl. 208. Engl. Bot. t. 495. Curt. Lond. fafc. 4. t. 17—Leaves ternate. Corolla extremely hairy on the upper fide. This elegant plant is common in boggy, marfhy fituations, and flowers in June or July. *Root* perennial, formed of fpreading fcyons, black. *Stem* leafy, fpreading horizontally, branched. *Leaves* ternate, on ftalks, toothed and flightly folded at the edge. *Flowers* in fpikes, bracteated, on ftalks, of a beautiful flefh-colour, hairy and very thickly fet on the upper fide with flefhy obtufe fibres. *Style* prominent. The whole herb is bitter, powerfully inducing perfpiration. Dr. Smith remarks that "an infufion of it was long ago recommended for the rheumatifm, and has been a popular medicine in England. It has alfo been given for the gout, fcurvy, ague, catarrh and dropfy, a formidable lift of diforders: if it has any right to fuch celebrity, it muft act as a powerful tonic."

7. M. *hydrophyllum*. Water-leaf Buckbean. Loureir. Cochinch. 105. Mart. Mill. Dict. v. 3—Leaves heart-fhaped, entire. Flowers axillary, crowded together. A native of fwamps in Cochinchina. This plant is confidered by the authors above quoted as forming a connecting link between *Menyanthes* and *Hydrophyllum*. The *ftem* is thread-fhaped and creeping. *Leaves* fmooth, on ftalks, fcattered, few in number. *Flowers* white, on long ftalks.

MENYANTHES *Trifoliata*, *Water-trefoil*, or *Buck-bean*, in the *Materia Medica*. The whole plant is fo extremely bitter, that in fome countries it is ufed for hops in the preparation of malt-liquor; and yet Linnæus obferves, that the poorer people in Lapland make a bread of the powdered roots mixed with meal, acknowledging at the fame time that it is a very unpalatable food. The blacknefs manifefted by adding a folution of green vitriol to the juice, or to a ftrong infufion of the leaves of buckbean, is a fufficient teft of its aftringency; while a drachm of the powdered leaves feldom fails to open the body, or produce vomiting; fo that in common with the tonic properties of a bitter, it feems farther to poffefs a confiderable fhare of medicinal activity: we can therefore more eafily credit the reports of its fuccefs in a great number of chronic difeafes mentioned by various authors, as fcurvy, dropfy, jaundice, afthma, periodical headaches, intermittents, hypochondriafis, cachexia, obftructio menfium, rheumatifm, fcrophula, worms, gout. Dr. Boerhaave was relieved in the laft mentioned complaint by drinking the juice mixed with whey; and Dr. Alfton tells us, that "this plant had remarkable effects in the gout, in keeping off 'the paroxyfms;' but adds, "though not to the patient's advantage."

In confirmation of the good effects of water trefoil in dropfies, we are told that fheep, when forced to eat it, are cured of the rot (oves tabidæ); yet as we have but few and imperfect proofs of its diuretic powers, this fact will be confidered of little weight.

Bergius confines the ufes of this plant to fcorbutus, leucophlegmatia, arthritis, rheumatifmus, cacoethes, and this fpecification is ftill farther contracted by later writers on the materia medica. In Lewis's Mat. Med. (by Mr. Aikin) it is faid, that the leaves of buckbean "have of late years come into common ufe as an alterative and aperient, in impurities of the humours, and fome hydropic and rheumatic cafes;" and as an active and eccoprotic bitter, we fhould fuppofe them not ill adapted to fupply the want of bile in the *primæ viæ*, and thus infer their ufe in protracted jaundice, and other biliary obftructions. Dr. Cullen has "had feveral inftances of their good effects in fome cutaneous difeafes of the herpetic and feemingly cancerous kind."

The leaves may be given in powder from ℈i to ℈ij for a dofe two or three times a day, but a ftrong infufion of them is perhaps preferable, and with delicate ftomachs it may be neceffary to conjoin a grateful aromatic: they impart their properties both to watery and fpirituous menftrua, and an extract

extract is ordered to be prepared from them in the Ph. Dan. p. 171. "Efficax et frequentis commodique usus." Murray. Lewis Mat. Med. Cullen Mat. Med. Woodville Med. Bot.

MENZABANO, in *Geography*, a town of Italy, on the river Mincio, famous for a battle fought here between the French and the Austrians, on the 28th of December 1801, in which, after a very obstinate and sanguinary contest, the former were victorious, and took 8000 prisoners.

MENZALE', called by Strabo (lib. xvii.) and the Arabian authors *Tanis* (which see), a large lake, separated from the Mediterranean, to which it is parallel, by a slip of land, about 60 miles in length and from 2 to 12 in breadth; filled and occasionally overflowed by the waters of the Nile. During the inundation the water is fresh, and becomes salt as the river returns into its bed; a circumstance which was observed in the time of the caliphs. The Nile, says the geographer of Nubia, overflowing its banks at the summer solstice, the canals which discharge themselves into lake Tanis, render its waters fresh; and the sea, flowing into it, in its turn, makes them salt. In this lake are islands with buildings in them like barns; but they are only accessible in boats. About 1200 boats, each of which pays annually 40 livres to the Pacha's renter, are constantly employed in fishing on the lake. The quality of the water gives to the fish a white flesh and a fine delicate flavour. They supply Damietta at a cheap rate. As the lake has several communications with the Nile and the Mediterranean, and being full of islands, reeds, herbs, and insects, it is abundantly stocked with fish. Two thousand persons are annually employed in the fishery, and thousands of birds constantly feed upon the fish without occasioning any perceptible diminution. The waters are covered with wild geese, ducks, teals, plovers, and ibises; and various other birds of large size and beautiful plumage. The islands in this lake are for the most part uninhabited, except Matarieh; and of course are uncultivated. Menzalé communicates with the sea by two mouths, *viz.* Dibé and Eumené Fareggi, which are the Mendesian and Tanitic mouths of the ancients; each mouth is shut towards the sea with a bar or bank, forming the part of a circle. The tongue of land, separating the lake from the sea, extends, with only four interruptions in its whole length, from Damietta to Tineh. The length of the lake from N.W. to S.E. is 43,000 fathoms, and its breadth from 12,000 to 26,000.—Also, a town of Egypt, situated near the lake to which it gives name; 20 miles S.S.E. of Damietta. N. lat. 31° 3'. E. long. 32°.

MENZALINSK, a town of Russia, in the government of Upha; 132 miles W.N.W. of Upha. N. lat. 55° 16'. E. long. 52° 14'.

MENZIESIA, in *Botany*, so named many years ago, by the writer of this, in the *Plantarum Icones ex Herb. Linn. fasc.* 3, in honour of his much-valued friend Mr. Archibald Menzies, F. L. S. This gentleman, in his voyage round the world with captain Vancouver, collected many rare and nondescript plants, particularly on the western coasts of New Holland and of North America. He also discovered, near Dusky bay in New Zeeland, the richest collection of *Jungermanniæ* that was ever, perhaps, made by any one person.—Sm. Plant. Ic. 56. Willd. Sp. Pl. v. 2. 355. Michaux Boreal-Amer. v. 1. 235. Juss. in Annal. du Muf. v. 1. 55. Ait. Hort. Kew. ed. 2. v. 2. 360. Swartz Tr. of Linn. Soc. v. 10. 375. Engl. Bot. v. 35. 2469. Lamarck Dict. v. 4. 115. Illustr. t. 285. Class and order, *Octandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Rhododendra*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, more or less deeply four or five-cleft, permanent. *Cor.* of one petal, inflated, nearly ovate, deciduous; its limb spreading, in four or five small, spreading, equal segments. *Stam.* Filaments eight or ten, thread-shaped, equal, shorter than the corolla, inserted into the receptacle; anthers erect, oblong, simple, two-lobed at the base, opening by two pores at the top. *Pist.* Germen superior, roundish-oblong, furrowed; style angular, erect, rather longer than the stamens; stigma obtuse, with four or five small lobes. *Peric.* Capsules elliptic-oblong, with four or five furrows, and as many valves and cells, opening from the top downward, the partitions double, formed of the inflexed margins of the valves. *Seeds* numerous, small, oblong, more or less pointed, affixed to the ribs of the large central column.

Eff. Ch. Calyx of one leaf, four or five-cleft. Corolla of one petal, inflated. Filaments inserted into the receptacle. Capsule superior, of four or five cells, the partitions from the inflexed margins of the valves.

1. M. *ferruginea*. Rusty-flowered Menziesia. Sm. Plant. Ic. t. 56.—Calyx very slightly four-lobed. Leaves obovato-lanceolate, finely serrated; smooth beneath.—Gathered by Mr. Menzies, very copiously, in 1787 and 1788, on the west coast of North America. The *stem* is shrubby, two or three feet high, determinately branched, spreading, round, smooth, the pale *bark* scaling off in long strips; *branches* leafy, hairy when young, springing from the same buds as the flowers, the scales composing which are ovate and fringed. *Leaves* alternate, crowded towards the tops of the branches, stalked, spreading, obovate, inclining to lanceolate, one and a half or two inches long, three-fourths of an inch broad, obtuse, tipped with a gland, finely serrated, fringed, membranous, flat, veiny; green and besprinkled with white depressed hairs above; pale and smooth beneath, except a few hairs, or flat narrow scales, on the ribs; deciduous. *Footstalks* short, winged. *Stipulas* none. *Flowers* from the buds of the last season, five or more together, on simple stalks, about an inch long, covered with viscid hairs, and drooping. *Calyx* small and flat, very slightly four-lobed, or rather waved at the edge, fringed. *Corolla* ovate, one-third of an inch long, the border four-cleft, slightly expanded, altogether (as appears by Mr. Menzies's drawing and description) of a rusty hue. *Stamens* eight. *Capsule* smooth, dark brown externally, pale within.

2. M. *globularis*. Pale-flowered Menziesia. Salis. Parad. t. 44. Ait. Hort. Kew. n. 1. (M. Smithii; Michaux Boreal-Amer. v. 1. 235.)—Calyx in four rounded lobes. Leaves obovate, nearly entire; glaucous and downy beneath.—Native of South Carolina, according to Salisbury and Lyon. Of this we know nothing but from the works quoted, by which it appears to differ from the foregoing, besides the above specific characters, in having a more globose *corolla*, pale yellow with red streaks. The *flowers* are octandrous and four-cleft, as in *M. ferruginea*. Michaux mistook this for the original species; and having no information of the specific name, gave one of his own. The above writers copy his error of the press.

3. M. *polifolia*. Irish Menziesia. Juss. in Ann. du Muf. v. 1. 55. Ait. n. 2. (Erica Daboeci; Sm. Fl. Brit. 420. Engl. Bot. t. 35. Willd. Sp. Pl. v. 2. 383. Andromeda Daboecia; Linn. Syst. Veg. ed. 13. 338.)—Calyx in four deep segments. Flowers racemose. Leaves ovate; very densely downy and snow-white beneath.—Native of hills in Spain and Ireland, on a boggy soil. Mr. Lambert found it abundant on Croagh Patrick in the county of Mayo, and Dr. Wade in the district of Cunnemara, county of Galway. In gardens it is often cultivated for ornament, amongst American and other flowering shrubs which thrive in bog earth,

earth, flowering from June to September. The *ſtems* are ſhrubby, buſhy, a foot and a half high, with many upright, ſimple, leafy branches, at length decumbent and ſpreading. *Leaves* numerous, ſtalked, generally alternate, now and then oppoſite, or three together, ovate, entire, ſlightly revolute; dark green, ſhining, and ſomewhat hairy above; ſnow-white, with denſe cottony down beneath, their ſmooth red rib vaniſhing about the middle. There are axillary tufts of numerous ſmall leaves beſides. *Flowers* four-cleft, octandrous, large, purpliſh-red, ovate, with four obtuſe angles, drooping in a long, looſe, inclining, bracteated cluſter; the ſtalks and calyx red, hairy, and viſcid. *Capſule* ſmall and roundiſh, with partitions from the inflexed margin of the valves, which is never the caſe with a real *Andromeda*. Hence this plant was retained in *Erica* in Fl. Brit. according to the original opinion of Linnæus, who was chiefly led by number in the parts of fructification. M. de Juſſieu however, who always much approved this genus of *Menzieſia*, has reinforced it with the preſent ſpecies, as Dr. Swartz has done with the two following.

4. M. *cærulea*. Scottiſh Menzieſia. Swartz Tr. of Linn. Soc. v. 10. 377. t. 30. f. A. Engl. Bot. t. 2469. (Andromeda cærulea; Linn. Sp. Pl. 563. Fl. Lapp. ed. 2. 133. t. 1. f. 5. Lapl. Tour. v. 1. 272. Fl. Dan. t. 57. A. taxifolia; Pall. Roſſ. v. 1. p. 2. 54. t. 72. f. 2. Erica cærulea; Willd. Sp. Pl. v. 2. 393.)—Calyx in five deep acute ſegments. Corolla ovate. Flower-ſtalks terminal, aggregate, ſimple. Leaves ſcattered, numerous, linear, obtuſe, finely ſerrated.—Native of turfy ſtony mountainous heaths in Lapland, Norway, ſome part of Siberia, and alſo in the moſt northern parts of America. It has lately been diſcovered at Aviemore in Strathſpey, as well as in the remote weſtern iſles of Shiant. This is a more humble *ſhrub* than the laſt, with the habit of an *Empetrum*, and diſtinguiſhed from all the foregoing ſpecies, by its narrow crowded *leaves*, like thoſe of a heath, moderately ſpreading in every direction. They are almoſt linear, about half an inch long, rather ſhining above, finely toothed at the edge; their rib downy underneath. *Flower-ſtalks* four or five at the top of ſome of the branches, at firſt perfectly terminal, but the branch gradually ſhoots beyond them; each is about an inch and a half long, ſimple, rough with red glandular hairs, drooping gracefully at the top, and bearing one large ovate *flower* of a pale blueiſh or livid red; the *calyx* in five deep acute ſegments. On turning to Pallas's *Flora Roſſica*, we find he did not alter the ſpecific name to *taxifolia*, from want of underſtanding the true meaning of *cærulea*, but becauſe the *corolla* occaſionally varies to fleſh-colour or to white; but theſe changes are frequent, and do not authorize ſuch a meaſure.

5. M. *empetriformis*. Bell-flowered Menzieſia. Sm. Tr. of Linn. Soc. v. 10. 380.—Calyx in five deep obtuſe ſegments. Corolla bell-ſhaped. Flower-ſtalks terminal, aggregate, ſimple. Leaves ſcattered, linear, obtuſe, finely ſerrated; concave beneath.—Gathered by Mr. Menzies on the weſt coaſt of North America, near Nootka Sound. A much taller plant than the laſt, with leſs crowded *leaves*, which are concave beneath, with a ſmooth rib; their upper ſurface ſhining; the margin fringed with briſtly ſerratures. The *flower-ſtalks* are crowded in like manner about the tops of the branches, but in greater number. *Calyx* not above half ſo long, with five blunt, thin-edged, deep, convex ſegments. *Corolla* ſmaller, bell-ſhaped, with five ſpreading, ovate, marginal ſegments, and not contracted at the mouth. *Capſule* almoſt globular, dark brown, beſprinkled with reſinous dots.

6. M. *Bryantha*. Moſſy Menzieſia. Swartz Tr. of Linn. Soc. v. 10. 378. t. 30. f. B. (Andromeda Bryantha; Linn. Mant. 238. A. Bryanthus; Pall. Roſſ. v. 1. p. 2. 57. t. 73. f. 1. Bryanthus; Gmel. Sib. v. 4. 133. t. 57. f. 3. Erica Bryantha; Willd. Sp. Pl. v. 2. 386.)—Calyx in four deep acute ſegments. Corolla bell-ſhaped, in four deep ſegments. Flower-ſtalks terminal, corymboſe. Leaves ſcattered, elliptic-oblong, toothed; convex beneath.—Gathered by Steller, on moſſy rocks in Kamtſchatka, flowering in July. This elegant little *ſhrub* is much ſmaller than any of the reſt, clothing the ground with its long trailing branching *ſtems*; and the ſmall, oblong, numerous *leaves* give it a moſs-like aſpect. The *flowers* grow four or five together in a ſmall, corymboſe, bracteated cluſter, on a long terminal ſtalk. The *calyx* and *ſtamens* are red. *Corolla* white, divided below the middle into four ſegments. Pallas ſays it has ſometimes five or ſix diviſions, and that the *ſtamens* are equal to them in number; but he muſt mean that they are twice as numerous, which indeed his figure expreſſes, and which is the caſe in the whole genus. The *capſule* is nearly globular, with four furrows. We have ſeen no ſpecimen.

Theſe are all the ſpecies of *Menzieſia* hitherto eſtabliſhed. Willdenow ſuggeſts, Sp. Pl. v. 2. 610, that the *Andromeda octandra*, Swartz Ind. Occ. 840, may belong to this genus; but Swartz deſcribes the corolla as permanent, and though he does not deſcribe the fruit, in a manner to aſſiſt us in this enquiry, we muſt preſume he did not overlook this plant of his own, while ſeeking for *Menzieſiæ* amongſt *Andromedæ*.

MENZIL, in *Geography*, a town of Africa, in the kingdom of Tunis, anciently called "Zæta;" 4 miles S.S.W. of Suſa.

MENZINI, Benedetto, in *Biography*, an eminent Italian poet, was born at Florence of indigent parents in 1646. He was taken at an early period into the houſe of Gianvincenzo Salviati, who gave him the means of cultivating his talents. He was ſoon diſtinguiſhed for eloquence, and opened a ſchool of rhetoric. By the advice of the celebrated Redi he turned his efforts to Italian poetry, and in 1674 publiſhed a volume of poems, dedicated to the grand duke Coſmo III., and in 1679 he publiſhed a treatiſe, entitled "Conſtruzione irregolare della Lingua Toſcana," and in the following year he appeared before the public with a volume of lyric poems, by which he obtained great reputation. In 1685 he accepted an invitation from queen Chriſtina of Sweden, then reſident at Rome, who gave him a very favourable reception, and admitted him into her academy. He had now leiſure to purſue his ſtudies, but the death of the queen in 1689 obliged him to ſeek a maintenance by writing for other perſons, particularly ſermons for the clergy who were unable to compoſe their own diſcourſes. He at length received from pope Innocent XII. an office in the church of St. Angelo, in Peſchiera; and in 1701 he was nominated coadjutor in the chair of eloquence at the college of the Sapienza at Rome. He died, according to one account, in 1704, but according to another in 1708. He wrote almoſt every kind of Italian poetry, but in anacreontic ſongs, in paſtoral ſonnets, elegies, and ſacred hymns, he has few equals, and perhaps no ſuperior; and in Italian ſatires none can compare with him. All the works of Menzini were collected and publiſhed at Florence, in four volumes, in the year 1731. Of theſe the firſt contains his lyric poems: the ſecond his miſcellaneous pieces: the third his Italian proſe; and the fourth his Latin compoſitions. He was a member of the academy Della Cruſca, and his works have been conſidered as belonging to the golden age of the language.

MEOLA, in *Geography*, a town of Italy, in the Treviſan; 11 miles E. of Trevigio.

MEPHITIS, or Mephitical *Exhalation*, denotes a poiſonous

poisonous and noxious steam issuing out of the earth. See DAMP, *Mephitic* AIR, and AZOTE. See also EFFLUVIA, and GROTTO *del Cani*.

MEPHITIS, in *Mythology*, is a name given to Juno, because she is supposed to preside over stinking exhalations, or corrupted and noxious air; and hence it was used to signify such noxious air itself. Servius, upon the passage in Virgil (Æn. vii) "Sævamque exhalat opaca Mephitim," says, that this goddess may possibly be Juno taken for the air, because it is by means of the air that bad smells are communicated. According to Scaliger, the word is Etruscan, and derived from the Syrians, with whom it signified any stinking smell. Juno had a temple among the Hirpines under this appellation.

MEPPEL, in *Geography*, a town of Holland, in the department of Overissel, seated on the Walt Aa; 24 miles W. of Covorden.

MEPPEN, a town and fortress of Germany, in the bishopric of Munster, at the conflux of the Hase and Embs; 52 miles N. of Munster. N. lat. 52° 43′. E. long. 7° 26′.

MEQUINENZA, a town of Spain, in the kingdom of Aragon, at the conflux of the Segre, the Cinea, and the Ebro; anciently called "Octogesa" and "Ictosa;" defended by a castle, and once the see of a bishop; 16 miles S.S.W. of Lerida.

MEQUINEZ, an imperial city of Morocco, greatly embellished and enlarged by Muley Ishmael, and the metropolis of the north. It is situated at the extremity of Beni-Hassen, 80 leagues N. of Morocco, and 20 leagues E. of Sallee and the sea. Maknassa, the founder of this city, built it at the bottom of a valley, but Muley Ishmael made it much larger, by building on the plain to the west. The city is surrounded by vallies and eminences highly cultivated, ornamented with gardens, and plantations of olive-trees, and watered by a variety of streams, so that the fruits and vegetables are of an excellent flavour. The winter is disagreeable on account of the quantity of mud which then accumulates in the city and its environs, because the streets are not paved, and the soil is clay. Mequinez is encompassed with walls: and the palace is fortified with two bastions, in which was formerly some small artillery. The Brebes have often conspired against the tyranny of its rulers; and on the western side are still seen some walls of circumvallation, six feet in height, which were probably only intrenchments for the infantry, as the attacks of the Brebes were sudden and momentary incursions, which did not require any long defence. In Mequinez, as well as in Morocco, there is a quarter walled in and guarded for the Jews. The houses are handsomer here than in that of Morocco; the Jews are more numerous, and derive greater profit from their industry, because the Moors of Mequinez are richer, and as they are nearer, they have greater intercourse with Europe than those of the Southern provinces. Contiguous to the quarter of the Jews, is another, inclosed with walls, but now in ruins, called the Negro town, built by Muley Ishmael for the families of his black soldiers; but of this the walls only remain. At the extremity of the city, on the S.E. side, is the emperor's palace, which is a very extensive building, including several gardens, well laid out and watered by abundant streams. In the centre is a large garden, surrounded by a spacious gallery supported by columns, which maintains a communication between the apartments. Those of the women are large, and terminate in a common chamber, built on a causeway that divides the great garden, where the women may look out at the window through an iron lattice. In passing from one apartment to another, we meet at intervals with regular courts, paved with squares of black and white marble. In the middle of these courts is a marble bason, on which is raised a round shell; in the centre of this is a fountain that plays into the bason. There are many other fountains that supply water for the numerous ablutions of the Mahometans. At Mequinez, as well as at Fez, they make a kind of glazed tiles, similar to what we call Dutch tiles, of various colours; which are used to pave their rooms and face their walls, and give to their houses an air of neatness and coolness, not occurring in other towns of the empire. The Moors of Mequinez are much more affable and engaging than those of the southern provinces; and the women are extremely handsome, being very fair, with fine black eyes, and beautiful teeth. They are sometimes seen walking on the terrace; but when a Moor appears, they immediately retire. At Mequinez, as well as at Morocco, there is a hospitium, or convent, of Spanish Recollects, founded more than 100 years ago by the munificence of the kings of Spain, for the benefit and spiritual comfort of the Christian captives. These convents are much respected in the country, both for the exemplary lives of the fathers, and the service they render to the poor, whom they supply with medicines gratis; 35 miles S.W. of Fez. N. lat. 33° 56′. W. long. 5° 50′.

MER, a town of France, in the department of the Loir and Cher, and chief place of a canton, in the district of Blois; 9 miles N.E. of Blois. The place contains 4300, and the canton 10,623 inhabitants, on a territory of 172½ kiliometres, in 12 communes. N. lat. 47° 42′. E. long. 1° 35′.

MER.—*Ouster le Mer.* See OUSTER.

MERA, in *Geography*, a town of Spain, in Galicia, near the sea-coast; 3 miles E. of Corunna.

MERA, in *Hindoo Mythology*, is the fabled wife of Haimavat and mother of Uma, a name and form of Parvati, thus incarnated to become the wife of Siva, and parent, or reputed parent, of Kartikya. (See KARTIKYA.) The stories connected with this fable are very numerous, filling many books in great esteem among the Hindoos. In the thirtieth and following sections of the first kanda, or book, of the Ramayana, it is detailed in a very poetical style how the "great Haimavat, sovereign of mountains, the grand magazine of metallic substances, had two daughters of incomparable beauty, by his wife Mera." Their names were Ganga and Uma. The first (the river Ganges) was yielded in marriage to all the celestials, at their earnest solicitation. Her younger sister, remaining a virgin, became a devotee of extraordinary rigidity, and was at length espoused by Siva, whose frigidity was, however, such as to require much address, on the part of the celestials, to animate him to the due pitch of passion; his nuptials and the consequent production of Kartikya being of great moment. On this occasion it was that Kama, the god of love, artfully placing the beauteous Uma before Siva, while in the graceful act of gathering flowers wherewith to decorate his emblem, the Linga had the audacity to launch an arrow at the dreaded deity. Siva, enraged, reduced Kama to ashes (or, according to some legends, to a mental essence) by a beam of fire, darted from his central eye. This fable is noticed in the article KAMA, and is as often alluded to in Hindoo books as any perhaps in the whole range of their mythological extravagance. In the Siva-purana, the parents of Parvati in this incarnation are named Himachala and Mahina, in other works Himalaya and Mena. (See MENA.) The name of the father, in all cases, being derived from a Sanscrit word meaning snow. Mera is said to be daughter of the mountain Meru; a most fruitful source of mythological tales of wonder and extravagance. See MERU.

MERAB, in *Geography*, a town of Arabia, in the province of Nedsjed; 100 miles N. of Jamama.—Also, a town of Persia, in Khorasan; 45 miles N.E. of Meschid.

MERA-COBIN, a town of Africa, in the kingdom of Adel, on the coast of the Indian sea. N. lat. 8° 10'. E. long. 49° 14'.

MERAN, a town of the Tyrol, of which it was formerly the capital, at the conflux of the Adige and Passer, containing six churches and convents; two miles S.S.E. of Tyrol. N. lat. 46° 38'. E. long. 11° 24'.

MERAT, a town of Hindoostan, in the country of Delhi; 40 miles N. of Delhi. N. lat. 29° 20'. E. long. 78° 6'.

MERATE, a town of Italy, in the department of the Serio; 9 miles W. of Bergamo.

MERATTE, a town of Algiers; 15 miles N. of Tagademt.

MERAUDABAD, or MOORADABAD, a town of Hindoostan, in Oude, once large with a mint, but now decayed; 20 miles N.E. of Sumbul.

MERBAT, a town of Arabia, in the province of Hadramaut, which, as well as Haseh, is only known for the traffic which the inhabitants carry on in incense produced in that neighbourhood; 32 miles N. of Dafar.

MERBES LE-CHATEAU, a town of France, in the department of Jemappe, and chief place of a canton, in the district of Charleroy. The place contains 661, and the canton 6382 inhabitants, on a territory of 122½ kiliometres, in 17 communes.

MERCADAL, the chief town of the Terminos Mercadal in the island of Minorca, situated nearly in the middle of the island on the great road between Mahon and Ciudadella. Its streets are narrow, winding, ill paved and worse repaired. The public edifices consist of the old parish church, which is decaying, and a new one. Its situation is the least salubrious in the whole island. During the extreme heats, the inhabitants are afflicted with obstinate fevers; water is scarce, as the great public cistern is often dry during the summer. The territory of this place is about 5½ leagues in length, and 4½ in breadth. In the same district, about four leagues from Mercadal, is Ferarias, where the English have constructed barracks for 200 soldiers. The territory of Ferarias is five leagues in length and two in breadth. Few of the occupiers are husbandmen, the greater number being employed in hunting, as game is very abundant.

MERCARA, a city of Hindoostan, and residence of the rajah of Coorga; 55 miles W. of Seringapatam.

MERCATI, MICHAEL, in *Biography*, a physician and naturalist, the son of Peter Mercati, a physician of St. Miniato, in Tuscany, was born in April, 1541. After having finished his scholastic education at his native place, he was sent to Pisa, and placed under the tuition of Cesalpini, from whom he derived his taste for the study of nature. Having received his degree of doctor in philosophy and medicine in that university, he went to Rome, where he soon became known to the pope, Pius V., who appointed him superintendant of the botanical garden of the Vatican, at the age of twenty-six. In the following year he obtained the esteem of Ferdinand I., the grand duke of Tuscany, who raised him to the rank of nobility; and soon afterwards the same dignity was conferred upon him by the senate of Rome. He was in great favour with pope Gregory XIII., who honoured him with an appointment about his person, and with his full confidence, as did also his successor Sixtus V., who conferred upon him the honourable office of apostolical prothonotary, and sent him into Poland with cardinal Aldobrandini, that he might enjoy the opportunity of increasing his collections in natural history. During this journey he greatly enriched his mineralogical cabinet, which he had already commenced at Rome. The same cardinal, when elected pope in 1592, under the title of Clement VIII., nominated Mercati his first physician, and had in contemplation higher honours to bestow upon him, when this able physician died, in 1593, in the fifty-third year of his age. His character in private life was universally esteemed, and the regret of the most distinguished persons of Rome followed him to his grave.

Mercati wrote in Italian, at the request of his patron pope Gregory, a work "On the Plague, on the Corruption of the Air, on the Gout, and on Palsy," which was printed at Rome, in 1576, in 4to: and likewise a "Dissertation on the Obelisks of Rome, printed in 1589, 4to. But he is principally remembered for his description of the subjects of natural history, particularly of mineralogy, contained in the museum of the Vatican, which was formed under the auspices of Gregory XIII. and Sixtus V. and was afterwards totally dispersed. He was about to prepare engravings of the principal subjects, when his disease, which terminated his life, interrupted his progress. His manuscript came into the hands of Carlo Dati of Florence, where it remained till the time of Clement XI., who purchased it, and caused it to be splendidly edited by Lancisi, his first physician, in 1717, under the title of "Metallotheca, opus posthumum Authoritate et Munificentia Clementis XI. Pont. Max. è tenebris in lucem eductum; operâ & stud. J. M. Lancisi Archiat. Prat. illustratum," folio. An "Appendix ad Metallothecam" was published in 1719. Eloy Dict. Hist. de la Méd. Gen. Biog.

MERCATOR, GERARD, an eminent Flemish geographer and mathematician, was born at Ruremond, in the year 1512. After he had attained a good degree of classical learning, he studied philosophy at Bois-le-Duc, and removed from thence to Louvain, where he was admitted to the degree of M.A. His studies now laid so fast hold of him, that he frequently forgot the usual periods for refreshment and sleep. At the age of twenty-four he married, and then began to learn the art of engraving. His first production in this way was a description and map of the Holy Land, which he published in 1537, when he was only twenty five years of age. In the year 1541 he made a terrestrial globe, which proved the means of introducing him to the patronage of the emperor Charles V., for whom he executed maps, globes, and a collection of other mathematical instruments. This business was the means of obtaining for him an appointment in the emperor's houshold. About the same time the duke of Juliers and Cleves made him his cosmographer. In 1551, Mercator produced his celestial globe, which was accompanied with a short treatise on the use of that instrument. He now left Louvain, and settled at Duysburg, where he published, at different periods, descriptions and maps of the World, Europe, Germany, France, and the British islands; these he afterwards collected together into an Atlas, to which he prefixed a treatise "On the Creation and Construction of the World." His method of laying down maps, &c. is a projection of the surface of the earth on a plane. (See MAP.) In 1568, Mercator published his "Chronologia" from the beginning of the world to that year, and immediately he gave the public a corrected edition of "The Geographical Tables of Ptolemy." He died of a paralytic stroke in 1594 at a very advanced age, and in the midst of his useful labours, at the same time projecting new works for the improvement of the science of geography. He was author of several other works besides those already noticed.

Of these the principal are as follow, 1. "Ratio scribendarum Literarum Latinarum, quas Italicas cursoriasque vocant:" 2. "De usu Annuli Astronomici:" 3. "Harmonia Evangelistarum." He had a son named Bartholomew, who wrote notes on John Sacrobosco's treatise "De Sphæra Mundi," when he was very young, as he died at the age of eighteen.

Mercator, Nicholas, an eminent astronomer and mathematician, was born in Danish Holstein about the year 1640. He received an excellent education, and his turn for mathematical studies introduced him to public regard and esteem in his country, and facilitated his correspondence with those persons who were eminent in the same sciences, in Denmark, Italy, and England. Receiving an invitation to visit this country, he came, and was so well pleased with the reception he met with, that he spent the remainder of his life in England. He was, soon after his arrival, elected a fellow of the Royal Society, and applied himself very diligently to the improvement of the sciences, but he has been charged with having borrowed the inventions of others, and adopting them as his own; and it appeared upon some occasions that he was not endowed with a very liberal mind in scientific communications. Thus, it had been observed before him, that there was an analogy between a scale of logarithmic tangents and Wright's protraction of the nautical meridian line, which consisted of the sums of the secants, though it did not appear by whom this analogy was first discovered. It seemed, however, that it was first published and introduced into the practice of navigation by Mr. Henry Bond, who mentions this property in an edition of Norwood's "Epitome of Navigation" printed about the year 1645, and he treated of it more fully in an edition of Gunter's works, printed in 1653, where he teaches, from this property, to resolve all cases of Mercator's sailing by the logarithmic tangents, independently of the table of meridional parts. This analogy had been only found to be nearly true by trials, but not demonstrated to be a mathematical property. Such demonstration was probably first discovered by Mercator, who, desirous of making the most advantage of this and another invention in navigation, invited, by a paper in the Philosophical Transactions for June 1666, the public to enter into a wager with him on his ability to prove the truth or falsehood of the supposed analogy. This proposal, not very reputable to a man of science and literature, was not taken up by any one, and Mercator reserved his demonstration: he, however, distinguished himself by many valuable pieces on philosophical and mathematical subjects. Of these we may mention "Cosmographia, sive Descriptio Cœli et Terræ in Circulos, &c.:" "Rationes Mathematicæ subductæ Anno 1653:" "Hypothesis Astronomica nova et consensus ejus cum Observationibus:" "Logarithmotechnia, sive methodus construendi Logarithmos, &c:" "Institutionum Astronomicarum Libri duo." He published also some papers in the Philosophical Transactions.

Mercator's *Chart*, or *Projection*, is a sea-chart, or projection of the surface of the earth in plano.

For the construction, use, advantages, &c. of which, see *Mercator's* Chart.

Mercator's *Sailing*, is that performed loxodromically, by means of Mercator's charts. See *Mercator's* Sailing.

MERCATORUM Festum, among the Romans, a festival kept by the mercantile people on the ides, or 15th of May, in honour of Mercury, to whom they sacrificed a sow; then sprinkling themselves with the water of a fountain, called aqua Mercurii, they prayed the god to prosper their trade.

MERCATUS, or Mercado, Louis, in *Biography*, an eminent physician of the 16th century, was born at Valladolid, in Spain, where he became a medical teacher, and obtained such reputation, as led to wealth and honourable appointments. He was first physician to Philip II. during a period of twenty years; and on the death of that prince, in 1598, was nominated to the same office by his son and successor, Philip III. Mercado lived to the age of 86; but the latter years of his life were rendered painful by the affliction of a stone in the bladder. He was author of a considerable number of works relative to medicine and surgery, written in a better Latin style than most of those composed by the writers of Spain; nevertheless, they are chiefly borrowed from the ancients, and contain nothing that is original. The whole were collected, and printed in three volumes, folio, in 1605, and have been several times reprinted. Eloy Dict. Hist.

MERCED, La, in *Geography*, a town of New Navarre; 90 miles S.W. of Casa Grande.—Also, a town of Chili; 50 miles S.S.W. of St. Yago.

MERCER, a county of Pennsylvania, bounded N. by Crawford, E. by Venango, S.E. by Butler, S. by Beaver, and W. by Ohio state; about 40 miles long, and 27 broad; containing about 642,000 acres, and 3220 inhabitants.—Also, a county of Kentucky, adjoining Woodford, Shelby, and Madison counties: it contains 9242 inhabitants, of whom 2169 are slaves. The chief town is Harrodsburg.

MERCHAB, or Merhab, a fortress of Syria, in the pachalic of Tripoli, on the coast of the Mediterranean, built by the Franks, and long possessed by the knights of St. John; 8 miles N. of Tortosa.

MERCHANT, Mercator, is one who buys and trades in any thing: and as merchandise includes all goods and wares exposed to sale in fairs or markets, so the word merchant formerly extended to all sorts of traders, buyers, and sellers. But every one that buys and sells is not at this day under the denomination of a merchant; only those who traffic in the way of commerce, by importation or exportation, or carry on business by way of barter or exchange, and who make it their living to buy and sell, by a continued assiduity, or frequent negociation in the mystery of merchandising, are esteemed merchants. Those who buy goods, to reduce them by their own art or industry into other forms than they are of, and then to sell them, are artificers, and not merchants. Bankers, and such as deal by exchange, are properly called merchants. Lex. Mercat. on Merch. Com. 23.

The mercantile profession is esteemed noble, and independent. In France, by two arrets of Louis XIV., the one of 1669, the other of 1701, the nobility are allowed to trade, both by land and sea, without derogating from their nobility: and we have frequent instances of merchants ennobled in that country, in regard to the utility of their commerce, and the manufactures they have set up. In Bretagne, even a retail trader does not derogate from nobility.

When the nobles of that province are disposed for commerce, they let their nobility sleep; that is, they do not lose it, but only cease to enjoy the privileges of their noblesse while their commerce continues; and re-assume it on their giving over trade, without any letters or instruments of rehabilitation.

In republics, trading is still more valued; but no where more than in England, where the younger sons and brothers of the best families are frequently bred up to merchandise. Add to this, that many of the Italian princes are the principal merchants of their states; and think it no discredit to make their palaces serve as warehouses; and that many of the kings of Asia, and most of those of the coast of Africa and

and Guinea, traffic with the Europeans, sometimes by their ministers, and sometimes in person.

There are companies of merchants in London for carrying on considerable joint-trade to foreign parts. See Company.

Besides these companies, there are other merchants who are distinguished by the country to which they trade; as Dutch merchants; West India merchants; Canary and Portugal merchants; Italian merchants, who trade to Leghorn, Venice, &c.; French and Spanish merchants.

The law of England, as a commercial country, pays a very particular regard to foreign merchants, in innumerable instances. Thus it is provided by Magna Charta, c. 30, that all merchants, unless beforehand publicly prohibited, shall have safe conduct to depart from, to come into, or tarry in, and to go through England, for the exercise of merchandise, without any unreasonable imposts, except in time of war: and if a war breaks out between us and their country, they shall be attached, if in England, without harm of body or goods, till the king, or his chief justiciary, be informed how our merchants are treated in the land with which we are at war; and if our's are secure in that land, they shall be secure in our's. Upon which Montesquieu remarks, with admiration, that the English have made the protection of foreign merchants one of the articles of their national liberty: and also, that the English know better than any other people upon earth, how to value at the same time these three great advantages, religion, liberty, and commerce. In this respect their disposition is very different from the genius of the Roman people; who, in their manners, their constitution, and even in their laws, treated commerce as a dishonourable employment, and prohibited the exercise of it to persons of birth, rank, or fortune; and equally different from the bigotry of the canonists, who looked on trade as inconsistent with Christianity, and determined at the council of Melfi, under pope Urban II. A.D. 1090, that it was impossible, with a safe conscience, to exercise any traffic, or follow the profession of the law. See Commerce.

If a difference arise between the king and any foreign state, alien merchants are to have forty days notice, or longer time, to sell their effects and leave the kingdom. 27 Ed. III. stat. 2. cap. 17.

The principal qualifications requisite for the profession of a merchant, are, 1. To know how to keep books single or double, *viz.* journals, ledgers, and others. 2. To draw invoices, contracts, charter-parties, policies of assurance, bills of exchange, letters missive, &c. 3. To know the relations between the money, weights, and measures, of several countries. 4. To know the places where the several kinds of merchandise are manufactured, in what manner made, what the materials composed of, and whence; the preparation the materials require before they are wrought; and the merchandises afterwards. 5. The lengths and breadths of stuffs, as silks, wools, hairs, linens, &c.; the regulations of the places where they are manufactured; and their different prices at different seasons. 6. The dyeing and the ingredients for the formation of the different colours. 7. The merchandises that abound or are more rare, in one country than another; their kinds and qualities; and the manner of trafficking in them to the best advantage, whether by land, by sea, or river. 8. The commodities permitted or prohibited, both for the import and export of a state. 9. The price of exchange, according to the course of several places, and what it is that raises or lowers it. 10. The duties to be paid, both at the import and export of wares, according to the usage of the place, the tariffs, regulations, &c. 11. The manner of packing, bailing, and tunning merchandises, to keep them either in magazines, or in voyages, &c. 12. On what terms a merchant vessel may be freighted and insured. 13. The goodness and value of every thing requisite for the construction or refitting of vessels, the prices of woods, cordage, masts, anchors, sails, and other necessaries. 14. The wages ordinarily given captains, officers, and sailors; and the manner of contracting with them. 15. The foreign languages, which may be reduced to four principal ones; *viz.* the Spanish, used almost through all the East, particularly on the coast of Africa, from the Canaries to the Cape of Good Hope; the Italian, used throughout the coasts of the Mediterranean, and many places of the Levant; the Teutonic, or German, used throughout most countries of the North; and the French, which is now become almost universally current. 16. The consular jurisprudence, the laws, customs, companies, colonies, chambers of insurance, consulates in the several countries; and, in general, all the ordinances, regulations, and policies, relating to commerce.

Merchant *Court*, or *Court-Merchant*, a kind of judicatory power, invested in merchants, chosen for that purpose, in several parts of Europe: in order to decide and determine, in a summary way, all differences and litigations among themselves and their dependents.

The affairs of merchants are accompanied with such a variety of circumstances, such new and unusual contingencies, which change and differ in every age, with a multitude of niceties and punctilios; and those again altering, as the customs and usages of countries and states do alter, that it has been found impracticable to make any laws that could extend to all cases: and our law itself does tacitly acknowledge its own imperfection in this case, by allowing the custom of merchants to pass as a kind of law in cases of difficulty. See Custom *of Merchants*.

Merchant, *Law*. See Law.

Merchant, *Tenant per Statute*. See Tenant.

MERCHENLAGE, Merciorum *Lex*, was the law of the people here called the Mercians. Camden, in his Britannia, says, that in the year 1016 this kingdom was divided into three parts; whereof the West Saxons had one, governing it by the laws called West Saxonlage, which contained these nine shires, *viz.* Kent, Sussex, Surrey, Berks, Hampshire, Wilts, Somerset, Dorset, and Devon; the Danes had the second, containing fifteen shires, *i. e.* York, Derby, Nottingham, Leicester, Lincoln, Northampton, Bedford, Bucks, Hertford, Essex, Middlesex, Norfolk, Suffolk, Cambridge, and Huntingdon, which was governed by the laws called Danelage: and the third part was in possession of the Mercians, whose laws were called Merchenlage, and contained eight shires, Gloucester, Worcester, Hereford, Warwick, Oxford, Chester, Salop, Stafford; from which three, king William I. chose the best, and with the other laws ordained them to be the laws of the kingdom. Camd. Brit. p. 94. See Common *Law*.

MERCIER, Bartholomew, in *Biography*, known under the name of the abbé St. Leger, was born at Lyons in 1784. He entered into the religious society of St. Genevieve, of which he became librarian. Louis XV. gave him the abbey of St. Leger of Soissons, of which he was deprived and reduced to indigence in the revolution. He died in 1799. Mercier was a man of erudition, and one of the first bibliographers in Europe. His works are, 1. "Letters on the Bibliography of Debure," 8vo.; 2. "Letters on the true Author of the Political Testament of Cardinal Richelieu;" 3. "Supplement to Marchand's History of Printing," 4to.; 4. "Letſer concerning the Maid of Orleans;" 5. "Diſſertation on the Author of the Book on the Imitation of Jeſus Chriſt (Kempis);" 6. "Notice of a rare Book, entitled 'Pedis Admirandæ,' by J. d'Artis;" 7. "On the Letters attributed to Pope Ganganelli;" 8. "Letters on different rare Editions of the 15th Century;" 8vo. 9. "Library of Romances," tranſlated from the Greek, 2 vols. &c. He was concerned in the Journal de Trevoux, and the Magazine Encyclopédique.

MERCHET. See MARCHET and BOROUGH-*Engliſh*.

MERCKLEIN, GEORGE ABRAHAM, in *Biography*, a learned phyſician, and ſon of a phyſician of the ſame name, was born at Weiſſemburg, in Franconia, in November 1644. His early education was conducted by his father; but he was afterwards ſent to the univerſities of Nuremberg and Wittemberg, and thence to that of Padua, which was then in the higheſt reputation; he returned, however, to Altorf, where he took his doctor's degree in 1670. He ſucceeded his father, in 1683, in the office of phyſician to the Teutonic order of the houſe of Nuremberg, and was ſubſequently appointed firſt phyſician to two princes palatine, who were grand maſters of this order. He paſſed a life of great activity, and is ſaid to have brought on a conſumption by the extreme ardour with which he purſued his occupations, which terminated his life in April 1702, at the age of fifty-eight. Mercklein was admitted a member of the Academy Naturæ Curioſorum, under the title of Chiron I., and communicated many memoirs on medical ſubjects, which were publiſhed in their Ephemerides. He was alſo author and editor of the following works. "Tractatio Medica curioſa de ortu et occaſu Transfuſionis ſanguinis," Nuremberg, 1679, 1715, in which he gives a hiſtory of this invention, and expreſſes forcibly his diſapprobation of the practice, which he calls cruel and dangerous. "Joſephi Pandolphini à Monte Martiano Tractatus de Ventoſitatis Spinæ, ſæviſſimo Morbo," ibid. 1674. "Lindenius renovatus," an augmented edition of the work of J. Ant. Vander Linden, "De Scriptis Medicis," in two volumes 4to., 1686, and "Sylloge Caſuum Medicorum Incantationi vulgò adſcribi ſolitorum, maximèque præ cæteris memorabilium," ibid. 1698, 1715, 4to.: a curious ſubject, but treated with too little diſcrimination between real and ſuppoſititious facts. Eloy Dict. Hiſt. Gen. Biog.

MERCŒUR, in *Geography*, a town of France, in the department of the Correze, and chief place of a canton, in the diſtrict of Tulles; 18 miles S. of Tulles. The place contains 825, and the canton 6971 inhabitants, on a territory of 225 kiliometres, in 11 communes.

MERCURIAL, ſomething that conſiſts of, or bears a relation to mercury, or quickſilver.

We ſay alſo, a mercurial perſon, to denote a perſon of a briſk, volatile complexion; ſuch perſons being ſuppoſed by aſtrologers to be under the more immediate influence of the planet Mercury. We ſay, mercurial fumes, mercurial ſpirits, &c. with reference to the mineral mercury.

MERCURIAL *Level*. See LEVEL.

MERCURIAL *Medicines*. See MERCURIALS.

MERCURIAL *Phoſphorus*, *Pump*, *Salivation*, *Thermometer*. See the ſubſtantives.

MERCURIAL *Unguents*, *Frictions*, &c. See SALIVATION.

MERCURIAL *Waters*. See WATER.

MERCURIALS, medicines compoſed or prepared of mercury, or quickſilver. See MERCURY in the *Materia Medica*.

MERCURIALI, GIROLAMO, in *Biography*, a learned and eminent phyſician, was born at Forli, in Romagna, in September 1530. The places at which he received his education are not accurately known, but probably were Bologna and Padua, at the latter of which he is ſaid to have received his doctor's degree; but ſome aſſert, that he graduated at Venice in 1555. He ſettled in the practice of his profeſſion at his native town, and at the age of 32 was delegated on ſome public buſineſs to pope Pius IV., at Rome. He evinced ſo much talent, and acquired ſo much eſteem at the pontifical court, eſpecially with cardinal Alexander Farneſe, that he was honoured with the citizenſhip of Rome, and was ſtrongly invited to reſide there. The opportunities which the public libraries and collections of antiquities in that metropolis preſented for the purſuit of his favourite ſtudies, led him to accept the invitation; and during his abode there, he not only employed himſelf in his profeſſional concerns, but ſtudied the claſſical literature, and the monuments of antiquity with great ardour. The reſult of theſe reſearches was a learned and elegant work, which acquired him much celebrity in the literary world, and which was firſt publiſhed at Venice in 1569, under the title of "De Arte Gymnaſticâ Libri ſex," 4to. It was many times reprinted. It is rather to be regarded as a philological than a medical performance; ſince, while it throws much light on the private life and cuſtoms of the ancients, its reaſonings and precepts are almoſt wholly derived from their ſchools. The reputation of this work brought him an invitation, in the ſame year, to the firſt medical chair in the univerſity of Padua, which he accepted, and was ſucceſſor to Anthony Francanzano, a man of ſuch high reputation, that he had been called the Eſculapius of his age. The character of Mercuriali, however, was not diminiſhed by the ſplendour of that of his predeceſſor, and his fame ſoon extended throughout Europe. In 1573 he was called to Vienna by the emperor Maximilian II., to conſult reſpecting a ſevere illneſs under which that perſonage laboured; and his treatment was ſo ſucceſsful, that he returned loaded with valuable preſents, and honoured with the dignities of a knight and count palatine. He had fulfilled the duties of his profeſſorial office during the period of eighteen years, and his ſtipend had been gradually augmented to a greater ſum than had ever been allotted to a medical chair, when, in 1587, he removed to Bologna, where he was attended by a numerous audience. This removal has been partly attributed to a degree of diſſatisfaction or ſelf-accuſation, in conſequence of an error of judgment, which had been committed by him and Capivaccio, ſeveral years before, when they were called to Venice, in order to give their advice reſpecting a peſtilential diſorder, which prevailed in that city. On this occaſion both he and his colleague ſeem to have fallen into the miſtake of ſeveral medical theoriſts, of denying the reality of contagion; and their counſels were ſaid to have been productive of extenſive miſchief. Nevertheleſs his reputation appears to have ſuffered little from this error; for he was invited by Ferdinand, the grand duke of Tuſcany, to ſettle at Piſa in 1599, where he was ordered a ſtipend of eighteen hundred golden crowns, which was ultimately raiſed to two thouſand. He had not reſided long at Piſa, however, before the ſevere calculous affections, under which he laboured, rendered him incapable of attending to his profeſſional and profeſſorial duties, and he retired to his native town. He ſunk under his diſorder in 1606, and was interred, with great honours, in a chapel, which he had himſelf erected at Forli. He left a large property in money and effects, among which was a valuable collection of pictures; and he made a great number of charitable bequeſts.

Mercuriali was a voluminous writer, as the following catalogue of his works will evince. He was a learned commentator on Hippocrates, and edited a claſſified collection of his

his works. Like the learned of his age, however, he was bigotted to the doctrines of the ancients, and fond of hypothetical reasoning, to the disparagement of sound observation; and he strongly imbued his pupils with the same erroneous principles. His first publication was a tract entitled "Nomothesaurus, seu Ratio lactandi Infantes." His second, the work "De Arte Gymnastica" before mentioned. 3. "Variarum Lectionum in Medicinæ Scriptoribus et aliis, Libri iv.," Venice 1571. 4. "De Morbis Cutaneis, et omnibus corporis humani Excrementis," ib. 1572. 5. "Tractatus de Maculis pestiferis et Hydrophobia," Basle, 1577. 6. "De Pestilentia in universum, præsertim verò de Veneta et Patavina," Venice 1577. 7. "Hippocratis Opera Græce et Latinè," ibid. 1578. 8. "De Morbis Muliebribus Prælectiones," Basle, 1582. 9. "De Morbis puerorum Tractatus locupletissimi," Venice, 1583. 10. "De Venenis et Morbis venenosis," ibid. 1584. 11. "De Decoratione liber," ibid. 1585. 12. "Consultationes et Responsa Medicinalia." Four volumes were successively published in 1587, 1590, and 1597; and were republished together after his death. 13. "Tractatus de Compositione Medicamentorum, De Morbis oculorum et aurium," ibid. 1590. 14. "De Hominis Generatione," 1597. 15. "Commentarii in Hippoc. Coi Prognostica, Prorrhetica, &c." ibid. 1597. 16. "Medicina Practica, seu, de cognoscendis, discernendis, et curandis omnibus humani corporis affectibus," Francfort, 1602, folio. All these works have been several times reprinted, and some of them were selected after his death, and printed together, under the title of "Opuscula aurea et selectiora," Venice, 1644, folio. Eloy Dict. Hist. de la Med. Gen. Biog.

MERCURIALIS, in *Botany*, is said to have been so named, in ancient times, after Mercury, its reputed discoverer. This etymology is at least as probable, if not so ingenious, as that preferred by Ambrosinus, who says *Mercurialis* is properly *Mulierculars*, because it is used by young wenches (*mulierculis*) as a laxative, in sallads. If the Linnæan *Mercurialis* be intended, certainly a very small dose would be sufficient, if not dangerous, and we cannot but suspect a confusion of different plants under the name in question. A similar error respecting the English name, Mercury, has crept into our article LINOZOSTIS, without any communication with the writer of the present. The plant called English Mercury is *Chenopodium Bonus-Henricus*, an excellent pot-herb, very nearly akin to Spinach; whereas the *Mercurialis*, or Mercury, properly so denominated, is a virulent poison, from the use of which, by mistake for the former, the most dangerous consequences have followed, as Ray and others relate. Such an error is the more carefully to be guarded against, as this poisonous plant is by far the most common of the two. See LINOZOSTIS and CHENOPODIUM.—Linn. Gen. 527. Schreb. 695. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 1083. Ait. Hort. Kew. ed. 1. v. 3. 408. Juss. 385. Lamarck Dict. v. 4. 116. Illustr. t. 820. Gærtn. t. 107.—Class and order, *Dioecia Enneandria*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juss.

Gen. Ch. Male, *Cal.* Perianth in three deep, ovato-lanceolate, concave, spreading segments. *Cor.* none, except the calyx be so considered. *Stam.* Filaments from nine to twelve, capillary, straight, the length of the calyx; anthers formed of a pair of globose cells.

Female, *Cal.* Perianth as in the male. *Cor.* none. Nectary of two sharp awl-shaped bodies, one at each side of the germen, and lodged in its furrow, but not always present. *Pist.* Germen superior, roundish, compressed, with a furrow at each side, hispid; styles two, reflexed, horn-like, hispid; stigmas acute, reflexed. *Peric.* Capsule roundish, pouch-like, two-lobed, of two cells. *Seeds* solitary, roundish.

Obs. *M. ambigua* is monoecious, and *M. annua* occasionally so. *M. afra*, mentioned by Schreber, is *Hydrocotyle villosa*, a plant of a totally different nature.

Ess. Ch. Male, Calyx in three deep segments. Corolla none. Stamens from nine to twelve. Anthers of two globes.

Female, Calyx in three deep segments. Corolla none. Styles two. Capsule two-lobed, of two cells. Seeds solitary.

1. M. *perennis*. Perennial Mercury, or Dog's Mercury.—Linn. Sp. Pl. 1465. Curt. Lond. fasc. 2. t. 65. Mill. Illustr. t. 91. Fl. Dan t 400. Engl. Bot. t. 1872. (Cynocrambe; Matth. Valgr. v. 2. 635. Camer Epit. 998, 999. Fuchs. Hist. 444. Ger. em. 333.)—Stem quite simple. Leaves rough. Root creeping. Common and plentiful in bushy places throughout Europe, in the spring, flowering in April or May. The *roots* are perennial, creeping and matted together to a great extent *Herb* fetid, dark green, roughish, 12 or 18 inches high, with a round unbranched *stem*, most leafy about the summit. *Leaves* opposite, stalked, ovate, acute, crenate, hairy, with membranous, reflexed, intrafoliaceous *stipulas*. *Flowers* green, always dioecious, in axillary, stalked, upright clusters. *Capsule* rough with hairs. When dried, the leaves often assume a blue tint, indicating the affinity of the genus to *Croton tinctorium*. This has been observed before, but we know of no experiments that have proved this plant useful in dyeing. That it is the λινόζωστις of Dioscorides, his description leaves no doubt, and he recommends it as a pot-herb, of a purgative quality. Possibly boiling, or the admixture of oily substances, may render it mild, and less dangerous.

2. M. *annua*. Annual, or French Mercury. Linn. Sp. Pl. 1465. Curt. Lond. fasc. 5. t. 68. Engl. Bot. t. 559. (M. mas et fœmina; Matth. Valgr. v. 2. 633, 634. Camer. Epit. 996, 997. Fuchs. Hist. 475, 476. Ger. em. 332. Dod. Pempt. 658.)—Stem cross-branched. Leaves ovate, smooth. Flowers racemose. Root fibrous.—Native of cultivated and waste ground, chiefly in the more temperate parts of Europe. It is common about London, Norwich, and some other towns, but not in the north of England; flowering in autumn. From the former it is readily distinguished by its fibrous annual *root*, and bushy *stem*. The whole *herb* moreover is smooth, of a deep shining green, smelling disagreeably, something like Elder. *Leaves* stalked, ovate, acute, serrated. *Spikes* much as in *M. perennis*, but there are no linear scales at each side of the germen, and the *capsule* is prickly or warty. A few male *flowers* are often found dispersed upon the female plant; and on the other hand, a few female ones upon the male now and then occur. The present species, like the former, is said to have been used as a pot-herb, and to be of an emollient quality. It is, we believe, the least virulent and dangerous of the two, but its nauseous flavour is not promising of any good property. The *seeds* are said by Lamarck to be very fattening to small birds, especially to the delicious Becafico, *Motacilla Ficedula*; which is not unlikely, considering the oily nature of several seeds in this natural order.

3. M. *ambigua*. Intermediate Mercury. Linn. Sp. Pl. 1465. Linn. fil. Dec. 1. 15. t. 8.—Stem cross-branched. Leaves ovate, nearly smooth. Flowers monoecious, in axillary tufts.—Native of Spain. Linnæus cultivated it in the Upsal garden, and found it constant from seed, yet its whole appearance is so like the last, that he was latterly disposed to

to think it a variety. The *flowers* however are not ſpiked, but grow, male and female together, in little axillary tufts, each flower on a ſimple ſtalk, the males moſt numerous.

4. M. *elliptica*. Shrubby Mercury. Lamarck n. 4. (M. luſitanica fruticoſa, amygdali folio; Tourn. Inſt. 534. M. tenuifolia fruticoſa perennis; Griſl. Luſit. 63.)—Stem croſs-branched, ſhrubby. Leaves elliptical, crenate, ſmooth.—Native of Portugal. Gathered near Faro by the abbè Durand. We have ſeen it alſo in Tournefort's herbarium. This is undoubtedly a very diſtinct ſpecies, unknown to Linnæus. The ſhrubby perennial *ſtem*, and the much ſmaller, elliptical, obtuſe, crenate, not ſerrated, *leaves*, at once diſtinguiſh it. The *flowers* are dioecious, axillary; the males in ſhort, denſe, ſolitary, ſtalked ſpikes; the females on ſingle-flowered, ſimple, ſhorter ſtalks, two or three together. *Germen* ſmooth and even, accompanied at each ſide by a ſmall, linear, whitiſh ſcale. The *leaves* and young twigs have often, in the dry plant, a reddiſh or purpliſh hue.

5. M. *longifolia*. Long-leaved Mercury. Lamarck n. 5.—Stem croſs-branched. Leaves oblong, downy, green, with blunt ſerratures. Fruit woolly.—Deſcribed by Lamarck from the herbarium of Thouin. Its native country is unknown. The *ſtem* is about a foot high, branched, ſlender and weak, ſlightly downy. *Leaves* ſtalked, ſpreading, oblong or ſomewhat elliptical, about an inch and half long, and not above five or ſix lines broad, being of a much narrower ſhape than thoſe of any other ſpecies. They are dark green, clothed on both ſides with depreſſed hairs, which render them rather ſilky; the margin ſerrated, with ſhort, blunt, glandular, curved teeth. *Footſtalks* about three lines long, with a pair of lateral glands at the top, and a pair of ſhort downy *ſtipulas* at their baſe. *Flowers* axillary, greeniſh, dioecious; the males in ſolitary, ſlender, ſtalked ſpikes; females ſolitary, on ſimple ſhort ſtalks. *Germen* and *capſule* hoary and woolly, accompanied by a ſlender ſcale at each ſide.

6. M. *tomentoſa*. Downy Mercury. Linn. Sp. Pl. 1465. (Phyllon arrhenogonon, ſive mariſicum; Ger. em. 333. f. 2; and Ph. theligonon, ſive fœminiſicum; f. 3.)—Whole plant finely downy and hoary. Stem ſomewhat ſhrubby. Leaves oblong, more or leſs ſerrated.—Native of Spain and the ſouth of France. Known from all the reſt by its white hoary aſpect, cauſed by the ſoft downy denſe hairs which clothe every part. The *ſtem* is moſt branched in the male plant, the *flowers* of which grow in little round heads, either ſolitary, or ſeveral one above another, on ſimple, ſolitary, axillary ſtalks. The female *flowers* are axillary, ſolitary, on ſimple ſtalks, on a ſeparate plant. Some female *flowers* nevertheleſs are occaſionally interſperſed on the former, as Gerarde's cut, borrowed from Cluſius, well expreſſes. The *leaves* of both are nearly ſeſſile, oblong, acute, veiny, generally more or leſs ſerrated, though ſometimes nearly entire. The ideas of the ancient botaniſts, from whence the above names originated, are truly abſurd. They not only miſtook the female plant for the male, on account of the ſhape of the capſule, in which they were pleaſed to find a certain anatomical reſemblance; but they gratuitouſly ſuppoſed that the herb, on account of ſuch reſemblance, would be efficacious in procuring male children, while the real male plant was preſumed to favour the generation of girls.

7 M. *indica*. Indian Mercury. Loureir. Cochinch. 628.—Stem ſhrubby, branched. Leaves alternate, lanceolate, ſmooth and naked. Styles three.—Native of Cochinchina, according to Loureiro, who ſays the freſh leaves, boiled in broth, have a mildly purging quality, without any bad effects; and that the plant is called *Rau mai*, or *Luc mai*. The *ſtem* is ſhrubby, ſtraight, ſix feet high, with round aſcending branches. *Leaves* alternate, lanceolate, ſerrated, ſmooth and ſhining. *Flowers* dioecious, lateral, of the proper ſtructure of a *Mercurialis*, except that the *germen* is ſaid to be three-lobed, with three *ſtyles*, which, as well as the alternate *leaves*, induces ſome ſuſpicion reſpecting the genus. We have ſeen no ſpecimen.

In the firſt edition of Sp. Pl. 1036, occurs a *Mercurialis procumbens*, not quoted by that name in any ſubſequent work of Linnæus. This however appears by the ſynonyms and his herbarium to be *Croton Ricinocarpus*, Sp. Pl. ed. 2. 1427. See CROTON, n. 90.

MERCURIALIS, in the *Materia Medica*, the ſpecies called French mercury, *Mercurialis annua*, with branched ſtalks, and ſmooth gloſſy leaves, grows wild in gardens and dunghills. This plant is mucilaginous, and was formerly much employed as an emollient. It was eaten like ſpinach, and when uſed in conſiderable quantity it opens the bowels. Accordingly Tournefort informs us, that the French made a ſyrup of it, two ounces of which was given as a purge; and that they uſed it in clyſters and peſſaries. mixing one part of honey with one and a half of juice. In England it is now diſregarded. A cataplaſm of the leaves has been recommended in pains of the limbs, in tumours, and even in ulcers, which it cleanſes and diſpoſes to heal. Poor people in country places uſe it as a cataplaſm for the rheumatiſm, and even for the gout. There is another ſpecies, called cynocrambe, and dog's mercury, *Mercurialis perennis*, which grows wild in woods and hedges: this, though more acceptable to the palate, as an oleraceous herb, than the foregoing, has lately been found to poſſeſs noxious qualities, and to act as a violent narcotic. (See Phil. Tranſ. N° 203.) In drying it turns blue, and ſteeped in water, it affords a fine deep blue colour; but which, Dr. Stokes ſays, is unhappily deſtructible both by acids and alkalies, and recoverable by no means that he hath been able to diſcover. Miller by Martyn.

MERCURIFICATION, in *Metallurgic Chemiſtry*, the obtaining the mercury from metallic minerals in its fluid form. See MERCURY in *Mineralogy* and *Chemiſtry*.

MERCURIO, in *Geography*, a town of Corſica or Golo, and chief place of a canton, in the department of Corté. The canton contains 2378 inhabitants.

MERCURY, ☿, in *Aſtronomy*, the ſmalleſt of the inferior planets, and the neareſt to the ſun.

The mean diſtance of Mercury from the ſun is to that of our earth from the ſun as 38710 to 100000: and his real diſtance from the ſun 36,841,468 miles. The eccentricity 7955.4. The inclination of its orbit, that is, the angle formed by the plane of its orbit with the plane of the ecliptic, is 7 degrees, and the ſecular change of the inclination by the action of the other planets + 20.43. The diameter of Mercury, meaſured by Dr. Bradley in 1723, in its tranſit over the ſun's diſc, with a micrometer to Huygens's teleſcope of 120 feet long, was found to be 10″.75; hence its diameter at the mean diſtance of the earth will be 7″.27. M. de la Lande, from the tranſit in 1753, found it to be 6″.5; and therefore it may be ſtated at 7″. Von Zach ſays, that the mean apparent diameter of Mercury is not ſo much as 7″, probably little more than 5″. Its real diameter to that of the earth is nearly as 0.4 to 1, or 3180 miles. The mean apparent diameter of the ſun at Mercury is = 80′; the denſity of Mercury to that of the earth is as 2.5833 to 1; its quantity of matter to that of the earth as 0.16536 to 1, the quantities of matter in ſpherical bodies being as the cubes of their diameters and denſities conjointly; the weights of equal bodies, or or gravities, on the ſurfaces of Mercury and the Earth, are as 1.0333 to 1, ſuch weights varying as the diameters and denſities conjointly: the place of the aſcending node of Mercury in 1750 $1^s\ 15^\circ\ 20'\ 43''$; ſecular motion of the node $1^\circ\ 12'\ 10''$; the annual motion of the node by the action of the other planets — 8.98; the preceſſion 50.25, and the motion in longitude 41.27. The place of the aphelion $8^s\ 14^\circ\ 22'$; the mean place of the planet $5^s\ 11^\circ\ 54'$; the motion of the aphelion in longitude in 100 years $1^\circ\ 34'$. The tropical revolution of Mercury $87^d\ 23^h\ 14'\ 33''$; the ſidereal revolution $87^d\ 23^h\ 15'\ 44''$. For further particulars ſee DENSITY, DIAMETER, DISTANCE, EXCENTRICITY, and PLANETS. As the intenſities of light and heat, which the planets receive from the ſun, vary inverſely as the ſquares of their diſtances from the ſun; and as the proportional diſtances of Mercury and the Earth are as 4 to 10, we ſhall have the inverſe ſquares $\frac{10^2}{4^2}$ to 1, or 6.25 to 1 for the relative intenſities of light and heat at Mercury and the Earth.

According to ſir Iſaac Newton, the heat and light of the ſun on the ſurface of Mercury, are almoſt ſeven times as intenſe as on the ſurface of the earth in the middle of ſummer: which, as he found by experiments made for that purpoſe by a thermometer, is ſufficient to make water boil. Such a degree of heat, therefore, muſt render Mercury uninhabitable to creatures of our conſtitution. And if bodies on its ſurface be not inflamed, and ſet on fire, it muſt be becauſe their degree of denſity is proportionably greater than that of ſuch bodies is with us. The revolution of Mercury round the ſun, or his year, has been already ſtated; but his diurnal revolution, or the length of his day, is not yet determined; nor is it certain whether he has ſuch a motion round his own axis or not.

What variety of weather or ſeaſons it may be liable to, we are ſtill at a loſs to determine; as not knowing the inclination of his axis to the plane of his orbit.

Mercury changes its phaſes, like the moon, according to its ſeveral poſitions with regard to the ſun and earth; except only that he never appears quite full, becauſe his enlightened ſide is never turned directly towards us, but when he is ſo near the ſun as to be loſt to our ſight in his beams. And as his enlightened ſide is always towards the ſun, it is plain that he ſhines not by any light of his own; for if he did, he would conſtantly appear round. This planet, when viewed with Dr. Herſchel's ten feet reflector, and with other teleſcopes, appeared much darker than any of the ſolar ſpots, and perfectly well defined; no irregularity of form having been perceptible at the moment of contact; but the obſervation appears to have been intermitted at the inſtant of the approach of the planet to the ſun's limb. Dr. Herſchel could not perceive the ſlighteſt degree of ellipticity in the form of the planet's diſc.

The ſituation of this planet proves evidently, that the hypotheſis of Ptolemy is falſe: for Mercury is ſometimes obſerved betwixt the earth and ſun; and ſometimes beyond the ſun. But the earth is never found between Mercury and the ſun; which however muſt happen, if the ſpheres of all the planets encompaſſed the earth, as a centre, according to the Ptolemaic ſcheme.

The diameter of the ſun, viewed from Mercury, would appear between two and three times as big as it appears on our earth; that planet being ſo much nearer to him than we are, and therefore the ſun's diſk would appear ſeven times as large as to us. Mercury's greateſt diſtance from the ſun, with regard to us, never exceeds twenty-eight degrees twenty minutes (ſee ELONGATION); whence it is ſeldom viſible, being commonly either loſt in the ſun's light, or, when the moſt remote from the ſun, in the crepuſculum. The beſt obſervations of this planet are thoſe made when it is ſeen on the ſun's diſk; for, in its lower conjunction, it paſſes before the ſun like a little ſpot, eclipſing a ſmall part of his body, only obſervable with a teleſcope.

The node from which Mercury aſcends northward above the ecliptic, is in the 15th degree of Taurus; the oppoſite in the 15th degree of Scorpio. The earth is in theſe points about the 6th of November, and 4th of May, new ſtyle; and when Mercury comes to either of his nodes at his inferior conjunction about theſe times, he will appear in this manner to paſs over the diſc of the ſun. But in all other parts of his orbit, his conjunctions are inviſible, becauſe he either goes above or below the ſun. The firſt obſervation of this kind was that of Gaſſendi, in November, 1631. Several ſubſequent obſervations of the like tranſits are collected in Du Hamel's Hiſt. of the Royal Acad. of Sciences, p. 470. ed. 2. See Dr. Halley's Accounts of the Tranſits of Mercury and Venus, in Phil. Tranſ. N° 193. See TRANSIT.

To an inhabitant of Mercury, the ſolar ſpots will appear to traverſe his diſc ſometimes in a right line from eaſt to weſt, and ſometimes elliptically. As the other planets are above Mercury, their phenomena will be nearly the ſame there as with us. Venus and the Earth, when in oppoſition to the ſun, will ſhine with full orbs, and afford a noble light to that planet.

TABLE

As a ſpecimen of the uſe of the preceding tables, we ſhall give the following example from the Aſtronomy of Profeſſor Vince, whoſe polite compliance with our wiſh to extract the preceding tables from his valuable work, demands our reſpectful acknowledgment.

To compute the Heliocentric Latitude and Longitude of Mercury, and Logarithm of his Diſtance from the Sun.—From Table I. of the epochs, take out the epochs of the mean longitude of the aphelion and node, for the given year, and place them in an horizontal line. But if the given year be not found in that table, take the neareſt year preceding the given year, as an epoch, and take out as before; under which (Table II.) place the mean motion, in longitude, of the aphelion and node, anſwering to the number of years elapſed ſince the epoch to the given year.

Under theſe, write down (Table III.) the mean motions of the ſame, for the given day of the month.

Under theſe, write down (Table IV.) the mean motions of the ſame, for the given hours, minutes, and ſeconds.

Add together the numbers in the ſeveral columns, rejecting 12 *S*, or any multiple thereof, if they occur; and you get the mean longitude, places of the aphelion, and node for the given time.

Subtract the longitude of the aphelion from the mean longitude, and the remainder is the mean anomaly.

With the mean anomaly enter Table V., and take out the equation of the orbit, making proportion for the minutes and ſeconds, if there be any, correcting the reſult of the proportion for ſecond differences.

Apply the equation, with its proper ſign, to the mean longitude, and you get the longitude on the orbit, from the mean equinox.

From the longitude of Mercury in his orbit, ſubtract the longitude of the node, and you get the argument, called the *argument of latitude.*

To the longitude on the orbit thus found, apply the reduction (Table VII.) with its proper ſign, and you have the longitude upon the ecliptic, reckoned from the mean equinox.

To the longitude thus found, apply the nutation, or equation of the equinoxes in longitude with its proper ſign, and you get the true longitude of Mercury on the ecliptic, from the true equinox.

With the argument of latitude enter Table VIII., and take out the heliocentric latitude, making proportion for the minutes and ſeconds, if neceſſary, correcting the reſult of the proportion for ſecond differences, and this is the true heliocentric latitude of Mercury.

With the mean anomaly of Mercury enter Table VI., and take out the logarithm of the diſtance, making proportion for the minutes and ſeconds, if neceſſary.

With the argument of latitude enter Table VII., and in the column *Sub. Log.* take out the number, making proportion for minutes and ſeconds, if neceſſary; and ſubtracting it from the logarithm of the diſtance laſt found, you have the logarithm of the curtate diſtance.

Example.—What is the heliocentric Latitude and Longitude of Mercury on June 3, 1793, at $5^h\ 17'\ 19''$, mean Time at Greenwich, and the Logarithm of his Diſtance from the Sun?

Mercury, in *Botany*, &c. See Mercurialis.

Mercury, *Engliſh.* See Chenopodium.

Mercury is a metal of a ſilvery-white colour, and fluid at the uſual temperature of the atmoſphere. It is known under a variety of denominations: the common name among the ancients was *hydrargyrum*, q. d. water of ſilver. The moderns commonly call it *mercury*, from ſome ſuppoſed relation it bears to the planet of that name. In Engliſh it is popularly called *quickſilver*, from its appearance. Many of the chemiſts call it *Proteus*, from the variety of forms, colours, &c. it paſſes through in their preparations.

§ 1. *Ores of Mercury.*

1. *Native Mercury; Gediegen queck-ſilber*, Wern.; *Mercure natif*, Haüy.

Its colour is that of ſilver.

It

It is found as globules in the cells of other ores of mercury, and as large maſſes in druſed cavities, &c.

When pure it is perfectly fluid; it feels very cold, and as if wet, but does not adhere to the finger. It has neither ſmell nor taſte.

Its luſtre is metallic ſplendent. Sp. gr. 13.568, Cavendiſh, Briſſon; 13.581, Haüy; 13.600, Klapr.

Native mercury is generally pure, but ſometimes it is amalgamated with ſome ſilver, though not ſufficiently ſaturated to be referrible to the following ſpecies, into which a tranſition is thus formed.

There are only a few places where native mercury has been found in abundance, ſuch as Idria, the Palatinate, and Spain; but in ſmall quantities it occurs almoſt always together with cinnabar and other mercurial ores, in fletz-rocks, which appear to be ſubordinate to ſome coal formation. See the ſequel of this article, and MINIUM.

For the uſe, and chemical and phyſical properties of mercury, ſee the ſequel of this article.

2. *Native Amalgam; Natürliches amalgam*, Wern.; *Mercure argental*, Haüy.

Its colour varies between that of tin and ſilver.

It is ſeldom found maſſive; oftener diſſeminated, in ſuperficial laminæ, and ſometimes cryſtallized. The cryſtals hitherto obſerved are: 1. The regular octahedron with all its edges truncated, mentioned by Romé de l'Iſle (Mercure argental *émarginé*, Haüy, pl. 65, fig. 24.) 2. The rhomboidal or garnet dodecahedron (Mercure argental *dodécaèdre*, Haüy, ib. fig. 25.) This occurs more frequently than the others, and is by Cordier conſidered as the primitive cryſtal. 3. The preceding truncated on the edges (Mercure arg. *triforme*, Haüy, ib. fig. 26.) Alſo the leucite cryſtal, or the double eight-ſided pyramid, flatly acuminated on each extremity by four planes ſet on the alternate lateral edges, is mentioned among the modifications of this ſubſtance.

The cryſtals are never large, generally of the ſize of a ſmall pea: they are uſually imbedded, ſeldom ſeveral of them grouped together.

Externally it is ſhining and ſplendent, but leſs ſo than native mercury: luſtre metallic. When ſcraped it becomes dull.

Fracture conchoidal. It is more or leſs ſoft, ſometimes approaching to fluid; not particularly brittle. Spec. grav. 14.1192, as a mean of ſeveral experiments by Cordier.

Beſides this paſty ſemifluid amalgam, there is a more ſolid variety, the fracture of which is more imperfectly flat conchoidal, ſometimes paſſing into fine-grained uneven, and which, when preſſed between the fingers, or cut with a knife, gives out a more creaking ſound than the other variety.

Expoſed to the fire the mercury is volatilized, and a button of ſilver remains.

The variety analyſed by Heyer contained 74 parts of mercury and 25 of ſilver: that examined by Klaproth 64 parts of mercury and 36 of ſilver; laſtly, Cordier found 72.5 of mercury and 27.5 of ſilver in the cryſtallized amalgam.

The native amalgam is of rare occurence; it has been found at Salberg in Sweden, at Roſenau and Niederſlana in Hungary, at Mörsfeld in the Palatinate, and principally at Moſchellandſberg and Stahlberg in Deuxponts, in a yellowiſh and reddiſh ferruginous clay, mixed with other mercurial ores, and accompanied with ſpathoſe iron, lithomarge, limeſtone, barytes, hornſtone, iron pyrites, &c.

Nothing exact is known reſpecting the mode of its occurrence; but probably it is confined to beds in fletz mountains.

The more ſolid variety reſembles ſilver, but may eaſily be known by the property it poſſeſſes of whitening gold and copper when rubbed on them.

3. *Mercurial Horn-Ore; Queck-ſilber horn-ertz*, Wern.; *Mercure muriaté*, Haüy.

Its uſual colour is aſh-grey, more or leſs deep; it often paſſes into yellowiſh-grey and greyiſh-white, and alſo inclines to greeniſh-grey.

It is ſeldom found maſſive or diſſeminated; but generally in thin cruſts formed by tubercular or ſmall globular maſſes, which are often compoſed of minute cryſtals. The form of theſe cryſtals is generally a dodecahedron like that of zircon, or rectangular four-ſided priſm, acuminated by four planes ſet on the lateral edges. (Mercure muriaté *dodécaèdre*, Haüy.) Beſides this the following modifications are mentioned by authors: a rectangular four-ſided priſm, acuminated like the preceding by four planes, but which are ſet on the lateral planes; a ſix-ſided priſm bevelled at both extremities, the bevelling planes ſet on the two largeſt oppoſite lateral planes; and the octahedron with ſummits and edges truncated.

Theſe cryſtals are always minute and irregular, often gibbous, whence the difficulty of determining their figure with exactneſs. Externally they are ſplendent, internally ſplendent with a complete diamond luſtre, ſometimes approaching metallic luſtre.

It appears to be compoſed of fine-grained diſtinct concretions. It is generally faintly tranſlucent, ſometimes only on the edges; ſoft; may be cut with a knife, and is eaſily frangible.

Its ſpecific gravity and other characters remain yet undetermined, on account of the ſmallneſs and ſcarcity of the fragments that have hitherto been found.

Before the blowpipe it is volatilized, without decompoſition. It is ſoluble in water. Woulfe found it compoſed of 64 parts of ſulphat of mercury, and 36 muriat of mercury; Kirwan of 70 parts of mercury, and 30 of muriatic and ſulphuric acids.

The Horn mercury, the ſcarceſt of all mercurial ores, was firſt diſcovered by Mr. Woulfe in the quickſilver mines of Moſchellandſberg and Mörsfeld, in ferruginous clayey ſand-ſtone, accompanied with other ores of mercury, ochrey-brown iron-ſtone, malachite and blue copper ore, calcareous ſpar, lithomarge, &c. It has alſo been found at Idria, generally in the cavities of an indurated clay, and of ſlate-clay accompanied with cryſtallized cinnabar; at Horzowitz in Bohemia, with dark red cinnabar in a vein of brown ironſtone, and at Almaden in Spain.

4. *Mercurial Liver-Ore; Queck-ſilber-Lebererz*, Wern.; *Liver-coloured mercurial ore*, Aik. *Mercure ſulfuré lituminifère*, Haüy.

It is divided by Werner into compact and ſlaty liver-ore.

a. *Compact.*—Its colour is intermediate between dark lead-grey and cochineal red.

Occurs maſſive and rarely diſſeminated. Internally it is gliſtening and glimmering, with ſemi-metallic luſtre.

Fracture even, paſſing ſometimes into fine-grained uneven, and imperfect large and flat conchoidal: fragments indeterminately angular, more or leſs blunt-edged; opaque. Streak ſhining, and of a deep cochineal red colour. It is ſoft, may be cut with a knife, and is eaſily frangible. Specif. grav. 7.186—7.352, Kirwan; 7.937, Gellert.

b. *Slaty.*—Its colour nearly the ſame as the preceding, only now and then more of the red obſervable on the principal fracture. It is found only maſſive. Its fracture in the direction of the laminæ is curved and thick ſlaty; it is ſhining, and its luſtre approaches the metallic; croſs fracture

 even

even and compact, and but little shining or only glimmering. Fragments more or less slaty. It is opaque, and uncommonly easily frangible.

The mercurial liver-ore affords upwards of 80 *per cent.* of pure mercury. Klaproth, who analysed the compact variety from Idria, obtained the following results:

Mercury	818
Sulphur	137.50
Charcoal	23
Silex	6.50
Alumine	5.50
Oxyds of copper	2
Copper	0.20
Water which served to form the sulphurated hydrogen gas, and other loss	7.30
	1000

This analysis, Klaproth adds, may serve to rectify the erroneous notions which have been adopted concerning the composition of this mixed mineral. By shewing that the sulphur is combined with the metal in the same proportion as in cinnabar, namely, as 1 to 6 in round numbers, we are taught how little foundation there is for the opinion of those who, like Sage and Kirwan, think that a part only of the mercury is in the state of sulphurated mercury, and that the other is in the state of a simple oxyd. If that were the case, the non-sulphurated part would certainly be soluble in the nitric acid; but experiment shews that this is not the case, because the acid cannot dissolve any part even when boiling, the mineral powder remaining unchanged at the bottom of the vessel. See Nichol's Journ. vol. 15. p. 231.

Both varieties of mercurial liver-ore occur together at Idria in Friaul, to which they appear exclusively to belong, though Spain, Siberia, and other places have been mentioned by authors among their localities. They are found in large masses, in and with slate-clay, and a kind of bituminous shale, and accompanied with cinnabar, and sometimes small quantities of native mercury and iron pyrites. Two ores of mercury, supposed to belong to the liver-ore, are at Idria distinguished by particular names. One is the *Brandertz*, which appears to be a kind of coarse coal impregnated with cinnabar; the blackish-grey variety contains only from 1 to 18 *per cent.*, the red from 30 to 40 *per cent.* of mercury. The other is called *Corallen-ertz*, (bead or coral-ore); it consists of reddish-black oblong beads of the size of a large coffee bean, of a foliated structure, imbedded in a blackish bituminous shale, and also in sand-stone. The richest affords about 40 *per cent.* of mercury.

5. *Cinnabar; Zinnober*, Wern; *Mercure sulfuré*, Haüy. This species may conveniently be subdivided into two varieties, *viz* dark red cinnabar and bright red cinnabar.

Dark red cinnabar; Dunkel-rother zinnober, Wern.

Its colour is cochineal red, which in some varieties inclines on one side to carmine red, on the other to lead grey.

It is found massive, disseminated, in superficial coatings and membranes, amorphous, cellular, dendritic, and crystallized.

Its primitive form is the regular hexahedral prism; integrant molecule, the triangular equilateral prism. The following, according to Werner, Emmerling, and Estner, are the principal secondary forms: 1. The rhomboid rather flattened, truncated in the two diagonally opposite obtuse angles. 2. The six-sided table, formed by the increase of the truncating planes of the preceding figure. 3. The regular six-sided prism, either perfect or acuminated by three planes set on the alternate lateral planes. 4. The three-sided pyramid, either double or single, in which the angles are sometimes more or less deeply truncated. 5. The regular octohedron, sometimes terminating in an edge at the summit.

Haüy, on the other hand, has observed only two distinct modifications in the crystals of cinnabar; the one is the primitive form, or the regular six-sided prism (Mercure sulfuré *primitif*, pl. 65. fig. 27.), in which the divisions parallel with the lateral planes are very distinct; the other (Merc. sulf. *bibisalterne*, fig. 28.) a similar short prism, with six marginal planes at each extremity placed alternately with regard to the lateral planes and to the planes of the other extremity.

These crystals, whose real form is often difficultly determinable, are generally small and very small; they are grouped together without order, generally lining the cavities of massive cinnabar. Externally they are splendent; internally both the crystallized and amorphous varieties are shining, which sometimes passes into glistening, and likewise into glimmering; with diamond lustre approaching to semi-metallic. The foliated varieties have the strongest lustre.

Fracture either more or less perfectly lamellar, the crystalline varieties with laminæ sometimes rather curved; or fine-grained uneven, with a tendency to conchoidal. Fragments indeterminately angular, rather blunt-edged. The lamellar varieties present granular distinct concretions; sometimes there is a tendency to thick and straight lamellar distinct concretions.

Massive cinnabar is opaque, seldom translucent on the edges; but the crystals are sometimes translucent and even approach transparent.

It becomes shining in the streak, affording a scarlet red powder. It is soft and easily cut with the knife, and very heavy. Spec. gr. varies from 4.500 to 10.218, which latter was determined by Brisson on a pure crystal from Almaden: 7.710, Klapr. (the Japanese in grains): 8.116, Ki. (the massive from Neumärktel).

The constituent parts of dark red cinnabar, were found by Klaproth to be

	The Japanese.	From Neumärktel.
Mercury	84.50	85.0
Sulphur	14.75	14.25
	99.25	99.25

Bright red cinnabar; Hochrother zinnober, Wern.

Colour bright scarlet red. It is found massive, disseminated, and coating. Internally it is glimmering, of rather a pearly lustre; sometimes, especially on the cross fracture, it is dull; principal fracture between earthy and fibrous; cross fracture earthy, fine-grained; fragments indeterminately angular, blunt-edged. It is opaque. Streak scarlet red, shining. It is very soft, passing into friable; and soils. It is very heavy.

This sub-species, which is much scarcer than the preceding, is found in the quicksilver mines of the Palatinate, particularly at Wolfstein and at Deuxponts, where it is accompanied with brown iron-stone, iron-ochre, quartz, calcareous spar, and dark red cinnabar. The other localities assigned to light red cinnabar are not well authenticated.

Some authors, as Estner, are said to have mistaken the red iron-

iron-ochre, which is found with bright red cinnabar, for this latter variety; whence the other shades of red they mention are not applicable to the substance in question.

Werner adopts two distinct formations of cinnabar, contemporaneous with the mountains in which they occur in beds. These latter, in the older formations, consist of a kind of chlorite slate, quartz, &c; in the newer, of slate clay, &c. It is also found in veins, the relative age of which is not ascertained. To the newer formation, which is far more abundant than the old, belong the repositories in the Palatinate, in Deuxponts, Spain, Idria, &c.; to the older, those of Hartenstein in Saxony, of Carinthia, &c. In veins it occurs at Horzowitz in Bohemia, in Lower Hungary, &c., where it is accompanied with some other mercurial ores, with iron-stone, galena, and other geognostically related species, which, in this case, are always indications of venigenous origin. When occurring in beds, it is generally accompanied (besides with other ores of mercury) with compact lime-stone, calcareous spar, barytes, quartz, and sometimes traces of copper ores; the beds themselves are principally formed by slate clay, a kind of sand-stone, and rocks of a similar nature. Some of the older beds are found in clay slate mountains, and contain the cinnabar in contemporaneous small veins or trums. The newer beds are supposed partly to belong to the coal-formation. Mohs.

The geognostic relations of the Japanese dark red cinnabar are not known. It is brought to us in small grains, being mostly fragments of flattened six-sided prisms, which partly contain finely disseminated iron pyrites, and are also found adhering to particles of a quartzy substance.

The principal quicksilver mines in the Palatinate are at the following places, *viz.* Mörsfeld, where the cinnabar traverses quartz, which is often completely coloured by it; the native quicksilver, formerly found at this place, was so abundant, that, according to Ferber, it was observed in the very streets of the town: Spitzenberg near Mörsfeld, where cinnabar occurs mixed with brown iron-stone; also small veins of asphaltum are sometimes found here in the masses of cinnabar: Carlsglück, which furnishes a mercurial sand ore, being cinnabar in a grey fine-grained and partly slaty sand-stone, mixed with more or less clay; also native mercury has sometimes been found here included in geodes of brown iron-stone: Wolfstein, where there is the mine *Theodors Erzlust*, in a mountain called the Königsberg; it was formerly uncommonly rich in mercurial ores, such as the light red cinnabar both earthy and fibrous, which is almost exclusively found here, accompanied with brown iron-stone, &c.: at Potzberg, in the principality of Veldentz, cinnabar occurs in a kind of pudding-stone.

In the territory of Deuxponts, the most remarkable mine is that in the Schlossberg of Obermoschel or Moschellandsberg, where both cinnabar and native mercury are found in great abundance.

The quicksilver mines of Idria were discovered in 1497. The richest ores, according to Ferber's account, occur in a considerable bed of clay slate. The roof and hanging side of the veins consist of limestone; they are very much rent, and travesed by dykes or ridges of other calcareous rocks and of a hard clay slate, which produce slips and faults in the mercurial vein. The clay slate of Idria is generally soft at some depth under ground, but harder and more distinctly slaty towards the surface: its principal colour is black. This slate is traversed and penetrated in all directions by veins of cinnabar and disseminated native mercury, which are also found in nests. It is in the softer part of the slate that the richer ores are generally found; they are firm, compact, and commonly marle-like, and when unmixed with other soft earthy substances, are susceptible of polish. These richer ores contain from 40 to 70 and even 80 pounds of quicksilver in the hundred weight.

The different rock-stones at Idria containing mercury are, 1. Grey and black lime-stone, improperly called horn-stone by the miners; it constitutes only the roof and sides of the slaty vein and the bars, which latter sometimes contain much disseminated cinnabar. 2. Varieties of clay of various colours, white, grey, yellow, red, and blackish, some pure others marly, and of various degrees of hardness: the blackish-grey variety yields from five to ten *per cent.* of quicksilver. 3. Grey clay slate, either pure or mixed with lime: it contains from two to three *per cent.* of quicksilver; the more its colour increases in depth the richer it becomes, so that the darkest, or blackish-grey variety, yields sometimes eight pounds in the hundred weight. 4. Black soft clay slate, called *Mildzeug*, of a more or less marly nature, and containing from ten to fifteen, and sometimes even from thirty to forty pounds in the hundred. 5. A black hard clay slate, called *Spiegel*, or looking-glass slate, on account of its shining surface: it sometimes produces from forty to fifty pounds in the hundred weight; but very little when purely argillaceous, and very hard. 6. Druses, or aggregations of calcareous, gypseous, and barytic crystals, which are sometimes found coated with cinnabar.

The following are the principal mercurial ores known at Idria: 1. Pure cinnabar, massive and crystallized. 2. Red ore, or impure cinnabar, of a tile-red colour, mixed with marle and pyrites; producing about thirty pounds in the hundred. 3. *Schnürl-erz*, or bead-ore, because the cinnabar traverses the matrix in small veins similar to strings of beads. 4. Mercurial liver-ore, a very rich ore, yielding from fifty to eighty pounds in the hundred weight. 5. Mercurial brand ore. 6. Coral ore, which contains from one to forty pounds. Vide supra *Mercurial liver-ore*.

The Spanish quicksilver mines are the most ancient we are acquainted with. Pliny informs us that no other cinnabar was made use of at Rome than that from Spain, particularly that of the *Regio Sisaponensis* in Bœtica, which appears to have been the territory of the present Almaden. This latter name is of Saracenian origin, signifying the shaft or gallery of a mine. According to Theophrastus' and Pliny's account, the cinnabar brought to Rome was a kind of sand; a term which is applicable to those small fragments of cinnabar mixed with quartz, which are still found in considerable quantity in the old mine de las Cuebas, near Almaden, from the size of a hazel-nut to that of a hemp-seed.

The prevailing mountain-rock at and near Almaden is a grey clay slate, traversed in many places by considerable beds of a breccia, which is composed of pieces of a similar clay slate, with white calcareous spots, and fragments of the same black bituminous shale, which is the usual concomitant of the quicksilver mines of Almaden. This breccia is here known under the name of *Frailesque*, on account of its prevailing colour, which resembles that of the habit of the Franciscan monks.

The most important mines are at the south side of Almaden, in the immediate neighbourhood of the town; there are six of them, running, within the space of about fifty fathoms, nearly from east to west: some of them, especially that of San Diego, deviate from this course, describing part of a large circle. Their dip is from sixty to upwards of eighty degrees; they frequently intersect each other, and are also traversed by the above-mentioned breccia and a black bituminous

minous ſhale; but at a certain depth (ſuch as in the mine Franciſco, which is 100 fathoms deep), they generally continue their courſe without interruption. They are all very rich in ore: where the veins meet, particularly thoſe of San Julian and San Diego, the repoſitories of ore are from four to five fathoms in thickneſs: theſe conſiſt of a quartz, richly intermixed with cinnabar, yielding from twenty to thirty pounds in the hundred.

The other quickſilver mines belonging to the territory of Almaden are, 1. That of Almadenejos, where veins of quartz, from one to half a fathom in thickneſs, richly penetrated by cinnabar, traverſe the grey clay ſlate above-mentioned. 2. That of Guadalperal, half a Spaniſh league N.W. from Almadenejos: this mine, which is very ſuperficial, was wrought by the Romans. The rock it traverſes is the ſame clay ſlate with that of Almaden, only that the breccia contains no fragments of the black bituminous ſhale, which is one of the component parts of that ſeen at Almaden. The ores of this mine conſiſt of cryſtalline cinnabar, moſtly in very narrow veins or trums. 3. The mine de las Cuebas, about three Engliſh miles from Almaden, in the ſame direction with that of Guadalperal. The quickſilver ores are here found in ſhort interrupted veins of quartz traverſing bituminous ſhale.

For a complete account of the quickſilver mines of Almaden, ſee Hoppenſack über den Bergbau in Spanien. Weimar, 1796.

Mercury, *Aſſay and Analyſis of the Ores of.*—Mercury is frequently combined with ſilver and biſmuth in the form of an amalgam. The mercury may be ſeparated by diſtillation in a retort of iron, or of glaſs coated with ſand and clay. The reſiduum, which is generally ſilver and biſmuth, may be diſſolved in nitric acid. When the ſolution is complete, a large quantity of water muſt be added, by which the greateſt part of the biſmuth will be ſeparated in the ſtate of ſubnitrat. If oxymuriatic gas be paſſed through the ſolution of ſilver and the remaining biſmuth, the former will be precipitated in the ſtate of muriat of ſilver, while the biſmuth will be held in ſolution in the ſtate of oxymuriat of biſmuth. When the muriat of ſilver is ſeparated, the biſmuth may be precipitated by potaſh, and the oxyd collected and dried. The ſubnitrat of this metal firſt ſeparated muſt be boiled with potaſh, to ſeparate the nitric acid. This oxyd, being waſhed and dried, may be added to the other. For every 100 of this oxyd, allow 90 of the metal. The muriat of ſilver contains, in the 100, 77.77 of the metal.

A ſpecimen of the native amalgam of ſilver and mercury, analyſed by Klaproth, gave 64 mercury and 36 ſilver in the 100.

Should any gold be preſent, it will be left undiſſolved when the reſidual metals are taken up by the nitric acid.

Native cinnabar may be analyſed by diſſolving it in nitro-muriatic acid. The mercury will be diſſolved in the ſtate of oxymuriat of mercury, while the ſulphur will be ſeparated. If much heat be employed, ſome of the ſulphur will be converted into ſulphuric acid, and ſome of the mercury, in conſequenee, will be thrown down in the ſtate of ſulphat: the ſolution, therefore, muſt be made in the cold.

The ſulphur being ſeparated, waſhed, and dried, may be weighed.

The mercury may be ſeparated in the metallic form by a clean piece of iron. This is almoſt the only inſtance in which a metal is precipitated by another in a ſtate of purity, ſince iron does not in any degree combine with mercury. The mercury may alſo be thrown down by the green ſulphat of iron. This ore, according to Klaproth, conſiſts of 84.5 mercury, and 14.75 ſulphur. The hepatic ore may be analyſed by a proceſs ſimilar to the laſt. This, however, is apt to abound with other ſubſtances beſides ſulphur and mercury. A ſpecimen from Idria was analyſed by Klaproth, and the reſult is given under the article *Ores* of Mercury, ſupra.

The native muriat of mercury conſiſts of a mixture of ſulphuric and muriatic combined with the oxyd of mercury. This ore muſt be reduced to a fine powder, and mixed with twenty-four parts of water; oxymuriatic gas muſt then be paſſed through it for a length of time, till the whole of the powder be diſſolved. The ſulphuric acid may be precipitated by muriat of barytes. The mercury may be precipitated from the muriatic acid by a bright piece of iron.

The ſulphat by this proceſs becomes oxyſulphat of mercury. In the ore it may be conſidered as the ſulphat: for every 100, therefore, of ſulphat of barytes precipitated, allow 211.76 of ſulphat of mercury in the ore. The reſt may be conſidered muriat of mercury. For 100 of mercury allow 4 of oxygen, and 11.2 muriatic acid.

For the aſſay of mercurial ores in the dry way, let the ſpecimen be pulverized, and accurately mixed with one-fourth its weight of quicklime, and an equal portion of iron filings, and then let it be pretty ſtrongly ignited in an iron or earthen retort, as long as any mercury comes over into the receiver.

The modes of extracting the metal from the ores of mercury are very ſimple. Meſſrs. Aikin, in their valuable Dictionary of Chemiſtry and Mineralogy, have given an account of the proceſs for this purpoſe at the mines of Deuxponts and of Idria, and alſo at Almaden in Spain. The former is the beſt and moſt ſcientific, and it is as follows: when the ore is brought out of the mine it is accurately ſorted, thoſe pieces being rejected which appear to be deſtitute of metal. The ſorted ore, being pulverized, is mingled with one-fifth, more or leſs, according to the proportion of cinnabar contained in the ore, of quicklime powdered by expoſure to the air. This mixture is then put into iron retorts, about forty or fifty in number, capable of holding about 60lbs. weight, which, thus charged, are fixed in a long furnace; a glaſs receiver is then attached to each retort, but not luted, and a gentle fire is applied in order to expel all the moiſture: when this is effected, the juncture of the veſſels is cloſely ſtopped with tempered clay, and a full red heat is applied for ſeven or eight hours, at the expiration of which time all the mercury will have been volatilized and condenſed in the receiver. The common produce varies between ſix and ten ounces of metal from 100lbs. of the ore.

The proceſs at Almaden is more rude and inartificial: it is deſcribed by Meſſrs. Aikin (*ubi ſupra*); and to their account of it the reader, deſirous of further information, is referred.

The conveyance of mercury from place to place requires, on account of its fluidity, extraordinary precautions. It is packed in the following manner. A freſh found ſheep-ſkin, the hair of which has been taken off, is laid over a wooden bowl, and a quantity, from 50lbs. to 75lbs. of mercury is poured into it: the ends of the ſkin are then gathered up, and tied together with great care, thus forming a ſort of bag in which the metal is incloſed: this bag is incloſed in a ſecond ſkin, and the ſecond in a third; and, laſtly, theſe bags are put into very tight barrels, capable of holding from two to four of them, and in this ſtate are brought into the market.

Chemical and Phyſical Properties of Mercury.—It is a white

white metal reſembling tin. Its ſpecific gravity is 13.568. It is liquid at the greateſt cold of this climate, but becomes ſolid at $-39°$, or $71°$ below the freezing point of water. It has frequently been reduced to the ſolid form in this country by the aid of freezing mixtures, and lately, by Mr. Leſley, in the vacuum of the air-pump. In this ſtate it poſſeſſes ſome of the characters of tin, as far as regards its appearance and malleability. It is ſaid to undergo a rapid decreaſe of volume immediately before congelation, a property the reverſe of what is obſerved in the freezing of water; and in the congelation of all bodies, the liquids of which are of greater ſpecific gravity than their ſolids, will it not be found that ſolid mercury is of greater ſpecific gravity than the liquid? The boiling point of mercury, or the temperature at which it aſſumes the elaſtic form, is 650°, or, as ſome ſay, 660°; ſo that the number of degrees between its freezing and boiling points is 689°, or 699°. This property admits of its being diſtilled, which furniſhes a ſimple method of ſeparating it from ſubſtances which are not volatile. Hence we may conclude, that if our natural temperature were more than 650°, mercury would be preſented to us in the form of a permanently elaſtic fluid: while, in a temperature leſs than $-39°$, it would be a ſolid malleable metal.

Mercury does not decompoſe water at any temperature, and hence it may be kept under that fluid without undergoing any change.

When expoſed to the air it ſoon tarniſhes, and becomes covered with a dark grey powder. If it be agitated with the fingers for a ſhort time, they become ſoiled with the ſame powder. This ſubſtance is produced by the mercury combining with the oxygen of the atmoſphere. It may be formed in greater quantity by a ſtronger agitation in contact with oxygen. This has been effected by putting a ſmall quantity of mercury into a large bottle, and tying it to the ſpoke of a coach-wheel. The change of ſurface, from the motion of the wheel, induces the rapid oxydation of the mercury. The oxyd ſo obtained is the firſt or protoxyd of mercury, and was called by the old chemiſts *Ethiops per ſe*. If, according to Dalton, the atom of mercury be 167, hydrogen being 1, and oxygen 7, the protoxyd will be $\frac{167 \times 7}{7} = \frac{100}{4}$, or four *per cent*. This is exactly what Fourcroy makes it by experiment. In taking a general view of the combinations of mercury with other bodies, it would appear that Mr. Dalton has rated the atom of mercury too high. The analyſis of the ſulphuret appears to be the moſt perfect. It may with much confidence be admitted, that 85 of mercury combines with 15 of ſulphur for the ſecond ſulphuret. Hence we ſhall have $\frac{15}{85} = \frac{26}{147\frac{1}{3}}$. We ſhall find, therefore, in treating of the other compounds, that it will be nearer the truth, to call the atom of mercury 147. This number will give the protoxyd 4.5 *per cent*. When mercury is diſſolved in nitric acid with a boiling heat, and the oxyd precipitated by lime water, the precipitate will be formed of a yellow colour. This is in all probability the ſecond oxyd, which ſhould be conſtituted as follows: $\frac{147 + 14}{14} = \frac{100}{8.7}$, or 8.7 oxygen, and 81.3 mercury. Chenevix makes it 10.7. It is likely, however, that as he expelled the acid by heat, the oxyd might abſorb more oxygen, or the acid might not be all driven off.

The third oxyd of mercury may be formed by expoſing the metal or the protoxyd in ſmall quantity in a large glaſs matraſs, the neck being drawn out to a ſmall point. When the mercury is heated in this veſſel to a boiling heat, 650°, the ſmallneſs of the aperture does not admit of its eſcape in vapour, while it is completely expoſed to the oxygen of the atmoſpheric air. By this means the mercury becomes converted into a red powder, which is the third oxyd. The ſame may alſo be procured by adding lime-water to a ſolution of the oxymuriat of mercury (corroſive ſublimate), when a beautiful red powder is precipitated, which is the oxyd in queſtion. The proportions will be $\frac{147 + 21}{21} = \frac{100}{12.5}$ or 87.5 mercury, and 12.5 oxygen.

This oxyd is of a beautiful red colour: it poſſeſſes ſome of the qualities of an acid, inaſmuch as it has a decided taſte, is corroſive to the ſkin, and when heated with the filings of tin or zinc, it cauſes them to inflame by yielding with facility its oxygen to them. Chenevix makes the proportions to be 85 mercury and 15 of oxygen, but for the reaſons given in the ſecond oxyd it is, doubtleſs, rated too high.

Mercury does not combine with carbon, hydrogen, or nitrogen, but it combines with ſulphur and phoſphorus.

When two parts of ſulphur and one of mercury are rubbed together in a mortar, the mercury combines with a portion of ſulphur. The whole maſs appears of a black colour, and conſiſts of the ſulphuret of mercury mixed with an exceſs of ſulphur. This ſubſtance was formerly called *Ethiops mineral*. If this maſs be expoſed to a heat ſufficient to ſublime the ſulphur, the exceſs of the latter ſubſtance eſcapes, leaving behind a ſubſtance of a deep violet colour. If this heat be continued the ſulphuret is ſublimed, which, if collected by a proper veſſel, will form a red cake, which, when reduced to powder and waſhed, conſtitutes the factitious cinnabar, known in the arts by the name of *Vermilion*. There appears to be two ſulphurets of mercury, *viz.* cinnabar, and one containing leſs ſulphur. The firſt will conſiſt of 8 of ſulphur and 92 of mercury, for $\frac{147 + 13}{13} = \frac{100}{7.1}$. The ſecond ſulphuret conſiſts of 15 ſulphur and 85 mercury, from what has been before ſtated. The ſecond ſulphuret of mercury has a beautiful ſcarlet colour, for which it is eſteemed in the arts as a pigment: it does not diſſolve in water and is perfectly taſteleſs. It does not change on expoſure to the air. When expoſed to a ſtrong heat the ſulphur combines with oxygen, and burns with a blue flame. Iron has a ſtronger attraction for ſulphur than mercury. Hence, if the red ſulphuret be mixed with iron filings and introduced into a retort, the iron combines with the ſulphur, and if the heat be ſufficiently raiſed, the mercury comes over in a ſtate of tolerable purity. This method is employed in the large way to ſeparate mercury from native cinnabar.

A method of preparing artificial cinnabar has been diſcovered by Mr. Kirchoff. To 300 grains of mercury add 68 grains of ſulphur, which being moiſtened with a ſolution of potaſh, muſt be rubbed together in a mortar which is not of metal. By this means the ethiops mineral is produced. To this ſubſtance 160 grains of potaſh, diſſolved in its own weight of water, muſt be added. Let the maſs now be transferred into a porcelain diſh and heated over a chemical lamp, adding water from time to time to ſupply the loſs by evaporation, in order to keep the ſolid ingredients covered.

covered. During this process it should be constantly triturated with a glass pistil. At the end of two hours the colour will begin to change from black to brown, and soon passes through different shades to a red. As the mass assumes the form of jelly, the red colour increases in brightness, and soon acquires its maximum of tint, at which time it will be proper to withdraw the heat, otherwise the colour declines to a dirty brown. It is recommended, that after it has acquired a tolerable good colour, it should be exposed for a few days to a low and uniform temperature, by which means the colour gradually improves and ultimately becomes exquisite. If the cinnabar thus obtained be exposed to a strong heat, it becomes brown and ultimately of a violet colour. It is highly probable, that this violet-coloured sulphuret is the first sulphuret produced from the second, from some of the sulphur being volatilized.

Phosphorus does not easily combine with mercury. Pelletier, however, succeeded in uniting these bodies by distilling a mixture of red oxyd of mercury and phosphorus. He observed that the red oxyd assumed a black colour before it combined with the phosphorus. Dr. Thomson, partly from this fact and from his own experience, is of opinion, that it is not the metal which unites with the phosphorus, but the black oxyd. In reasoning from analogy we might be apt to doubt this fact. We know that when sulphur is heated with an oxyd of mercury, the oxygen of the latter combines with a portion of sulphur, and is carried off in the state of sulphurous acid gas. Then since phosphorus has a stronger attraction for oxygen than sulphur, it would seem likely that the mercury would be reduced to its metallic form before it combined with the phosphorus. This, however, is not a fair conclusion, since none of the compounds of phosphorus are volatile. The circumstance of sulphurous acid being elastic, is doubtless a strong reason why the metals in the metallic sulphurets are generally free from oxygen.

The phosphuret above alluded to is a solid of a black colour: its consistency is such as to be cut with a knife. When exposed to the air it exhales a vapour smelling like phosphorus.

Mercury combines with most of the metals forming alloys, which have been called amalgams. Many of these compounds are of great use in the arts.

Gold unites with mercury with such facility, that if a piece of pure gold be singly dipped into it, it comes out completely covered with mercury. When the gold is divided into small grains and heated red-hot, the mercury being heated near to its boiling point, the gold almost instantly dissolves. A considerable proportion of gold may be added in this way without materially altering its liquidity. If, however, this liquid amalgam be squeezed through sheep's leather, an alloy will be obtained of almost any degree of consistence. The amalgam of gold used for gilding is about the consistency of paste. The substance to be gilt, which is copper, brass, or silver, is first covered with mercury, in order to form a medium for covering the surface with the amalgam. When the surface of silver is clean, the mercury combines with it with great facility. Copper or brass do not take the mercury by the same mode of application. A dilute nitric acid is added to the mercury, by which a portion of the metal is dissolved. If a small quantity of this solution be applied to the brass or copper surface, the mercury becomes precipitated upon it, and is instantly made fit to receive the amalgam. A small quantity of the amalgam, more or less, according to the thickness of the gilding required, is laid upon the quicksilvered surface, and uniformly spread about with a brush. The substance is then held over a clean coke or charcoal fire, and thus alternately heated and brushed till all the mercury is evaporated, leaving the gold firmly and uniformly adhering to the surface.

Mercury does not combine easily with platina in masses. If, however, the precipitate from nitromuriatic acid by muriat of ammonia be exposed to a strong heat, the acid and oxygen are expelled, leaving pure platina in a state of minute division. If the mercury be mixed with this powder and heat applied, an alloy will be formed, from which an amalgam of any degree of consistence may be obtained by squeezing through leather. This amalgam may be employed for coating metals, such as silver, brass, and copper. The metallic precipitate of platina above-mentioned, might be obtained at little expence, probably not more than the price of silver. Vessels of copper might, therefore, be covered with platina without much increasing their intrinsic value.

We hope, therefore, that artists in this line will take the hint. Even if no other end should be gained than preventing the deleterious effects of copper, the object is worth attention.

Silver easily amalgamates with mercury. When the proportion is eight of mercury to one of silver, the mass is capable of assuming a crystalline form. The specific gravity of this compound is greater than an arithmetical mean, a proof of considerable affinity between the two metals. This amalgam, like the two last, may be employed to coat copper and brass with silver.

Copper is capable of combining with mercury. The alloy, however, is not of any use, and has been little examined.

Mercury does not combine with iron. This circumstance presents many advantages. Iron vessels are well calculated for conveying mercury from place to place, and iron retorts are well fitted for distilling that substance. There are some disadvantages in mercury not uniting with iron. If the surface of iron could be covered with mercury like copper, &c. it might be gilt with as much facility as those metals. Although it is generally considered as incapable of uniting with mercury, it is stated in Crell's Journal, that Mr. Vogel has succeeded by the following process. Take half an ounce of iron-filings and one ounce of alum, and rub them together to a very fine powder; add to this from an ounce to an ounce and a half of mercury, and triturate till the amalgam begins to be formed; then pour in a little water, and continue the agitation for an hour: the alum is now to be dissolved out and the amalgam of iron will remain behind.

Tin combines easily with mercury. It is this alloy which constitutes the silvering of glass reflectors. A piece of tinfoil is first cut to the size of the glass plate to be silvered. This sheet is spread upon a smooth and perfectly flat stone, at first truly horizontal, but capable of being placed in an inclined position. The sheet of tinfoil is then covered with mercury, till the whole of the surface appears perfectly bright and liquid. The plate of glass, perfectly clean, is then laid upon the tinfoil. A number of weights are also laid upon the glass-plate, and the stone put into an inclined position by a lever, and held in that situation by temporary props. By this means the excess of mercury is squeezed out, and runs off by a groove in the edge of the stone. As much mercury is left with the tinfoil as will form a tolerably hard alloy.

Mercury unites with zinc in any proportion. This alloy is employed in a friable state for the purpose of laying on the

the cushions of electric machines, which much increases their exciting power.

It is also employed in the process called *similoring*. An amalgam of the consistency of that used for gilding is applied, in a manner similar to the gilding amalgam, to the surface of copper. The mercury evaporates by heat, leaving the zinc behind. The latter, however, does not appear in its pure state, but combines a portion of copper, and by that means produces a fine yellow surface, little inferior to gold, but in fact it is nothing more than brass formed by the union of the copper with the zinc. This process is employed by the button-makers. Some sorts of buttons are first covered all over with this yellow coating. The upper surface of the button is afterwards really gilt.

Mercury is readily alloyed with lead, bismuth, and antimony: the second of these is frequently used to adulterate mercury. It may contain a considerable portion of bismuth without sensibly losing its liquidity.

Salts of Mercury.—The salts of mercury are generally distinguished by their nauseous taste. Those that constitute the greatest part are insoluble in water. They form several varieties from the oxyd of mercury, assuming different states of oxydation, and also from their aptness to exist in the state of sub and super-salts.

Sulphat of Mercury.—Sulphuric acid does not act upon mercury without the assistance of heat. The acid is then partly decomposed. An atom of oxygen is separated, which combines with the mercury. The acid flies off in the state of sulphurous acid. Indeed this is the best way of getting this gaseous acid in a state of purity. The oxyd of mercury unites with another portion of the acid, forming the sulphat of mercury which separates in the form of white powder. In this experiment the sulphuric acid should not be in excess, since in that case the super-sulphat of mercury would be obtained. This salt dissolves in 500 parts of water at 60°, and in 287 at 212°. On evaporation it affords small prismatic crystals. It is not changed by exposure to the air, but is decomposable by heat. According to the analysis of Fourcroy, it is composed of 12 acid, 83 of the second oxyd of mercury, and 5 water. If we consider the atom of mercury 147, oxygen 7, and sulphuric acid 34, the atom of the second oxyd will be $147 + 2 \times 7 = 161$: then for the sulphat we have $\frac{161 + 34}{34} = \frac{100}{17.4}$, or 17.4 acid, and 82.6 of the second oxyd of mercury.

Super-sulphat of Mercury.—When an excess of sulphuric acid is boiled upon mercury, the oxyd combines with two atoms of acid, constituting the super-sulphat of mercury. It has a disagreeable acrid taste. It is not changed by exposure to the air. It changes vegetable blues to red. Fourcroy says that when the acid amounts to $\frac{1}{12}$th of its weight, it is soluble in 157 of cold, and 33 of boiling water, and observes that it is differently soluble with different proportions of acid. This is the first instance in which we have heard of the acid of a salt being so unlimited, and we cannot help doubting the accuracy of the above fact. In all the instances in which super-salts have been analysed, they have been found to contain a double dose of acid. Considering it therefore as such, we have $\frac{161 + 2 \times 34}{2 \times 34} = \frac{100}{29.7}$, or 29.7 acid, and 70.3 base.

Super-oxysulphat of Mercury.—This salt is described by Dr. Thomson as the oxysulphat, but the proportion of acid given by the analysis of Messrs. Braumcamp and Sigueira-Oliva, shews it to be a super-salt. When mercury is boiled with an excess of acid, and the heat continued longer than in the formation of the last salts, some of the excess is decomposed, giving another atom of oxygen to the mercury, while sulphurous acid gas is disengaged. The oxyd, therefore, combines with an excess of oxygen, and then this oxyd combines with an excess of acid, which constitutes the super-oxysulphat. This salt is sparingly soluble in water, and affords small crystals of the shape of prisms.

According to the chemists above-named, it is composed of 31.8 acid, and 63.8 peroxyd, and 4.4 water. According to hypothesis it will consist as follows: $\frac{168 + 68}{78} = \frac{100}{28.9}$, which gives 28.9 acid, and 71.1 peroxyd.

Oxysulphat of Mercury.—The salt which has been called *Turbith mineral*, has been supposed to be a sub-oxysulphat of mercury. If, however, we can depend upon the analysis of Braumcamp and Sigueira-Oliva, we can only consider it an oxysulphat. It is in the state of a yellow powder, and was formerly much used in medicine. It has, however, been laid aside on account of its extreme severity of operation. According to the above chemists it is composed of 15 acid, 84.7 peroxyd, and 0.3 water. If we consider it as a sulphat, we shall have $\frac{168 + 34}{34} = \frac{100}{16.8}$, which gives 16.8 acid, and 83.2 of the peroxyd. If such a salt exists as the sub-oxysulphat, it will be found to consist of 9.2 acid, and 90.8 peroxyd; for $\frac{168 \times 2 + 34}{34} = \frac{100}{9.2}$. It does not appear likely that such a mistake could be made in an analysis. The difference between the sub and the neutral salt is nearly six *per cent* of acid. It may, therefore, with some confidence be concluded, that *Turbith mineral* is the oxysulphat of mercury, and not a sub-salt, as has been supposed.

Nitrat of Mercury.—When nitric acid of a mean strength is poured upon mercury, a brisk effervescence ensues, induced by the disengagement of nitrous gas. When the acid is much diluted, and the mixture kept cool by placing the vessel in a large mass of cold water, the solution goes on very slowly. By this means every atom of mercury decomposes an atom of nitric acid, taking an atom of oxygen, by which an atom of nitrous gas is evolved. The atom of oxyd so found unites with two atoms more of nitric acid, forming the salt in question. It will be proper to observe here, that there is a seeming anomaly as well in this as in most of the soluble nitrats, and in a great number of carbonats. Although we call them indiscriminately nitrats and carbonats, they are, strictly speaking, super-nitrats and super-carbonats. We may almost generally conclude, that those salts which have been called nitrats are super-nitrats; while those which have been denominated sub-nitrats will prove, on analysis, to be nitrats simply. We cannot, however, at present make this distinction without some further experiments.

When the above solution is carried to a certain extent, or the dilute solution evaporated, the salt very easily affords

crystals,

cryſtals, which are in the form of four-ſided pyramids, baſe to baſe.

When ſulphuretted hydrogen is paſſed through a ſolution of nitrat of mercury, the hydrogen combines with the oxygen of the mercury, forming water, while the ſulphur combines with the mercury, and falls down in the form of ſulphuret.

A ſolution of muriat of tin added to this ſalt precipitates the mercury by combining with its oxygen. The cryſtals of nitrat of mercury detonate upon burning coals, and explode with phoſphorus by the blow of a hammer. No analyſis of this ſalt has been given by chemiſts, but from the weight of its conſtituent atoms it will be as follows: $\frac{147 + 7 + 2 \times 19}{2 \times 19} = \frac{100}{19.3}$; which gives 19.3 of acid, and 80.7 of the protoxyd.

Oxynitrat of Mercury.—When mercury is diſſolved in nitric acid with the aſſiſtance of heat, an atom of mercury decompoſes two atoms of the acid, while two other atoms of acid unite with the oxyd ſo formed, conſtituting what is called the oxynitrat, but which is in fact a ſuper-oxynitrat. If this action goes on with a little water the ſalt ſoon forms into a yellow cryſtalline maſs, which ſhews a marked difference in the character of the two ſalts, ariſing from the baſe of this ſalt having a larger proportion of oxygen. If water be added in conſiderable quantity to the ſolution of this ſalt, a portion of it loſes one atom of acid, and is converted into a yellowiſh powder, which falls to the bottom of the veſſel. This has been improperly called a ſub-oxynitrat. From the analyſis it appears to be a nitrat.

On paſſing ſulphuretted hydrogen gas through a ſolution of the oxynitrat, it becomes reduced to the nitrat, and is ſaid, by Zaboada, to combine with ſulphur. It is more likely, however, that the ſulphur would be converted into ſulphuric acid, and that the precipitate is a ſulphat of mercury. When muriat of tin is added to a ſolution of this ſalt, inſtead of reducing it to the metallic form, which is the caſe with the nitrat, it reduces it merely to the ſtate of the protoxyd, which combines with the muriatic acid to form muriat of mercury. Its components will be known from the following analogy: $\frac{161 + 38}{38} = \frac{100}{19.1}$, which gives 19.1 of acid, and 80.9 of the ſecond oxyd.

The ſalt which has been called ſub-oxynitrat, but which from its analyſis muſt be the oxynitrat, was formerly called *nitrous turbith*, from its reſemblance to the ſulphat. It has been analyſed by Meſſrs. Braumcamp and Sigueira-Oliva, who make it to conſiſt of 12 acid, and 88 ſecond oxyd.

By treating this ſalt as the oxynitrat ſimply, we ſhall ſee that the proportions by hypotheſis agree nearly with the above analyſis: for $\frac{161 + 19}{19} = \frac{100}{10.5}$, or 10.5 acid, and 89.5 of the ſecond oxyd.

Beſides the oxynitrat already deſcribed, which contains the ſecond oxyd, a ſalt may be formed with the third oxyd, ſo that we have three ſalts formed with the three oxyds; namely, the nitrat, the oxynitrat, and, for the ſake of diſtinction, the laſt might be called the hyper-oxynitrat. This laſt ſalt cannot be formed by boiling the nitric acid with mercury, but by directly diſſolving the third oxyd in nitric acid. Muriat of ſoda cauſes no precipitation from a ſolution of this ſalt, ſince the oxyd is at a maximum of oxydation, and is all employed in forming the ſuper-oxymuriat.

Muriat of Mercury.—Muriatic acid has no action upon mercury, but readily combines with its oxyds, forming with the firſt a muriat of mercury, and with the third or peroxyd an oxymuriat, or rather, as we ſhall ſhew, a ſuper-oxymuriat. The old method of making the muriat was by triturating four parts of the oxymuriat with three parts of metallic mercury, till the latter totally diſappeared. By this proceſs the peroxyd in the oxymuriat gives up as much oxygen to the metal as makes the whole into the protoxyd, which, with the exceſs of acid in the oxymuriat, forms the whole into a ſimple muriat. The maſs ſo produced is put into a matraſs capable of holding about four times the quantity of matter which is put into it. This being ſet in a ſand bath, and the heat raiſed, the muriat of mercury ſublimes into the upper part of the matraſs. The veſſel is now broken, and the ſublimed matter carefully ſelected. This, however, is frequently mixed with a little of the oxymuriat, which is to be ſeparated by repeated ſublimations, or by waſhing in water, the oxymuriat being ſoluble while the muriat is not ſo. It would appear that this method was invented long before the component parts of the ſalts were known. The metallic mercury added to the oxymuriat is much too little. If we conſider the oxyd in the muriat as being the protoxyd, the metal ought to be to the oxymuriat as 294 to 212. If the running mercury were leſs there would be an exceſs of oxymuriat. This experiment is very important in ſhewing that the oxyd of mercury in the muriat is the protoxyd. If it were the ſecond oxyd, 212 parts of the oxymuriat ought only to take up 73.5 of running mercury. The above proceſs, however, ſhews that 212 of the oxymuriat takes up 159 of mercury, and ſtill ſome of the oxyſalt is found in exceſs after ſublimation. Although in this proceſs 212 parts of the oxymuriat, by trituration with 294 of mercury, would form 462 of the protoxyd; the acid in the oxymuriat will not be ſufficient to form the whole into a muriat. The acid in 212 parts of the oxymuriat is 44, which will combine with 308 of the protoxyd, to form 352 of the muriat. This quantity ought to be ſublimed, leaving behind 154 of the protoxyd. If, inſtead of employing 212 of the oxymuriat to 294 of mercury, we make their proportions as 212 to 192, we ſhould get 352 parts of the muriat, as before; but the reſiduum will conſiſt of 52 parts of the peroxyd. The Edinburgh form for calomel, or muriat of mercury, is four parts of corroſive ſublimate (oxymuriat of mercury) to 3.5 of running mercury.

In the above proportions of 212 to 192, in which the reſiduum is 52 of peroxyd, the proportions reduced to their loweſt terms, are 4 to 3.6; for $\frac{212}{192} = \frac{4}{3.6}$. If, however, this proceſs were carried on with the greateſt economy, 212 parts of the oxymuriat ſhould be triturated with 294 of mercury, and 22 of real muriatic acid. The whole of the matter will, in this caſe, be ſublimed in the ſtate of muriat, which will be 528 parts, while in the common way only 352 of this ſalt is obtained.

Muriat of mercury may be formed in the humid way with much more convenience, and probably cheaper. This proceſs was firſt propoſed by Scheele. He diſſolved the mercury in nitric acid, with heat, and then added to the ſolution a ſolution of muriat of ſoda. A precipitate was formed, which, when well waſhed with hot water, was the muriat of mercury, which has been called by the names of *calomel* and *mercurius dulcis*.

This proceſs has been much improved by diſſolving the mercury in a dilute nitric acid, without heat. In Scheele's proceſs

process the mercury was converted into the second oxyd, which, when the muriat of soda was added, about three-fourths of the muriat were formed, and one-fourth of oxymuriat of mercury. By dissolving the mercury slowly, nothing but the protoxyd is formed, and not the least proportion of oxymuriat will be left in the solution, after the muriat is precipitated.

The oxyd of mercury in the muriat, as we have before shewn, is the protoxyd, that of oxymuriat being the peroxyd; but the oxyd of the oxynitrat is, in all probability, the second oxyd. It will appear, therefore, from theory, and experience confirms it, that one part of the second oxyd in the nitrat gives up an atom of oxygen to the other part, and thus dividing the resulting salts into muriat and oxymuriat, the former being precipitated, while the latter remains dissolved in the liquid. This idea is strongly confirmed by experiment. If lime-water be added to the oxynitrat a yellow oxyd is precipitated, which is the second oxyd. If lime-water be added to the muriat precipitated from the oxynitrat, the black or first oxyd is obtained; but if the same be added to the liquor from whence the muriat has been precipitated, the red or third oxyd will fall down. If the mercury be dissolved in dilute nitric acid in the cold, the simple nitrat will always be formed, in which the oxyd is a protoxyd. The whole of this oxyd will combine with the muriat, when the muriat of soda is added to form the muriat of mercury. This is by far the most simple and safe process for making calomel. If the mercury be dissolved with heat, the oxyd of the nitrat will be the second oxyd, which constitutes the oxynitrat. When muriat of soda is added to this, one-half of the mercury combines with an extra atom of oxygen, at the same time the other loses an atom, reducing one-half to the protoxyd, and the other to the peroxyd; the former combines with the muriatic acid to form muriat of mercury, the other combines with another portion of acid to form the oxymuriat. This latter salt is then divided into a super and a salt, the former remaining in solution, the latter falling down with the muriat. Hence it will appear, that when the oxynitrat is used, we do not obtain a pure muriat. An improved method of subliming calomel has been invented, which may be considered a valuable discovery. Instead of subliming it into a cake, as in the old way, it is sublimed into water. By this means the salt is completely freed from any soluble matter. The muriat of mercury, when pure, is in the state of white powder. It is nearly insoluble in water, requiring 1152 parts of boiling water to dissolve 1 of this salt. By exposure to the air it becomes of a deeper colour. It sublimes at a heat less than that required to sublime the oxymuriat. Hence it happens, that the latter salt is always attached to the under side of the sublimed cake of the former, when the two salts are sublimed together. This affords the means of their separation, by detaching the oxymuriat and subliming again. When the muriat is mixed with water, and oxymuriatic gas passes through it, it is converted into oxymuriat of mercury. Nitric acid dissolves it with the disengagement of nitrous gas. The result becomes a mixture of oxymuriat and oxynitrat. The last fact furnishes an easy method of analysing the salt, and has been taken advantage of by Chenevix and Zaboada. When it is dissolved in nitric acid, nitrat of silver precipitates the muriatic acid. The former chemist by this means found 100 parts of the salt or calomel to consist of 11.5 parts of muriatic acid, and 88.5 protoxyd, or 79 of mercury, and 9.5 of oxygen. The latter chemist, from 100 grains of the salt, obtained 10.6 of acid; he then precipitated the mercury with muriat of tin, which amounted to 85 grains: the rest was oxygen, which was 5 *per cent.*, very nearly agreeing with that above given, which was 4.5 *per cent.* By the latter, therefore, we have 10.5 muriatic acid, and 89.5 of protoxyd of mercury. By hypothesis $\frac{147 + 7 + 22}{22} = \frac{100}{12.5}$. This gives 12.5 muriatic acid, and 87.5 of protoxyd.

Calomel nine times sublimed forms what some have called the "Mercurial Panacea."

Oxymuriat of Mercury.—This salt is generally known by the name of *corrosive sublimate.* It has long been known for its dreadful effects on the animal system when taken on the stomach in too large a quantity, and as a medicine in moderate doses. It was understood by the alchemists, and has been tolerably well described by Albertus Magnus.

A great variety of processes has been invented for preparing it, most of which are complicated and uncertain. We shall, therefore, give the direct method only, which is simple and economical.

We have seen in the formation of the muriat of mercury, by triturating it with running mercury, that if the oxymuriat had not an extra dose of acid, as well as an extra dose of oxygen, the proportion of acid in the oxymuriat ought to be less than that in the muriat, because no addition of acid is employed with the running mercury. We must consider the salt in question, therefore, not as the oxymuriat of mercury, but the super-oxymuriat. It was some time ago assumed by Gay Lussac, as a principle, that in all salts in which the bases combined with an extra dose of oxygen, the acid was increased in a proportionate degree. The present salt and some others seem to countenance such an opinion, but the principle is far from being general. We have many instances of super-salts without an increase of oxygen in the base. There are also oxy-salts without an increase of acid. In the oxysulphats of mercury above treated, one of them has merely an excess of oxygen in the base of the salt. The other has both an excess of oxygen and an excess of acid, the first being a sulphat, and the second a super-oxysulphat. The oxysulphat of iron has no extra dose of acid; since the nitric acid alone, when too great a heat is not applied, is sufficient to convert the green sulphat into the red or oxysulphat. This salt, however, is frequently resolved into two distinct salts, *viz.* the super-oxysulphat and a sub-salt, a proof that an excess of base is as common to the oxy-salts as an excess of acid. The oxymuriat of mercury may be prepared by directly adding muriatic acid to the red or peroxyd of mercury. The solution affords crystals by evaporation. It may also be formed by passing oxymuriatic gas through a solution of the nitrat of mercury, or through a mixture of water with any of the oxyds of mercury, and then evaporating the solution to obtain the salt in crystals. In making the muriat by adding muriat of soda to the solution of oxynitrat of mercury, it has been shewn that the second oxyd is divided into the protoxyd and the peroxyd, the former combining with one atom of acid, forming the muriat, which falls down; the other portion combining with two atoms of acid, forming the salt in question, and remaining dissolved in the liquid. It would appear that this latter salt could not be formed if an excess of muriatic acid were not present, in order to give to the oxymuriat its double dose of acid. The solution of mercury in the nitric acid has generally an excess of acid, which disengages muriatic acid from the muriat of soda, to make up for this demand. It would be worth while to make the experiment with a saturated solution of nitrat of mercury, and with a neutral solution of muriat of soda. Would an oxymuriat of mercury, strictly speaking, be formed? Or would this salt be resolved into a sub-oxymuriat of mercury, and a super-oxymuriat? Experiment must decide

cide

cide this point. The oxymuriat of mercury has generally been employed in medicine and the arts in the ſtate after ſublimation. It is then a white ſemitranſparent maſs in needle-formed priſmatic cryſtals. Its aggregation is very great, on which account it is ſcarcely ſoluble in cold water. If, however, it be rubbed in a mortar with boiling water, it diſſolves nearly $\frac{1}{3}$d of its weight. When cold, however, it does not retain more than $\frac{1}{19}$th. The oxymuriat, therefore, made by ſublimation, ſhould not be attempted to be diſſolved in cold water, becauſe of its great aggregation.

When this ſalt is formed by evaporation, or when its cryſtals are formed in the humid way, it is more to be depended upon. Theſe cryſtals will immediately diſſolve in three or four parts of boiling water, and in about 20 of cold water. The form of the humid cryſtals is that of quadrangular priſms, rather rhomboidal. An analyſis of this ſalt has been made by Chenevix, by Zaboada, and by Meſſrs. Braumcamp and Sigueira Oliva. The firſt makes it

18	Muriatic acid
82	Peroxyd, *i. e.* 69.7 mercury, and 12.3 oxygen.
100	

The ſecond	19.5	Acid
	80.5	Peroxyd
	100	

The latter	18.8	Acid
	81.2	Peroxyd
	100	

We ſhall ſee from the following calculation, that this ſalt is ſuper-oxymuriat of mercury; the acid 2×22, the oxygen 3×7, and the mercury 147; $\frac{147 + 21 + 44}{44} = \frac{100}{20.7}$, which gives 20.7 acid, and 79.3 of peroxyd.

The neutral oxyſulphat would be $\frac{147 + 21 + 22}{22} = \frac{100}{11.6}$, or 11.6 acid, and 88.4 of peroxyd; ſo that the near agreement in the above analyſis, and their great difference from this laſt ſtate, leave no doubt of the ſalt in queſtion being a ſuper-ſalt.

It is frequently a matter of much importance to be able to detect the preſence of this ſalt, particularly when it has been adminiſtered as a poiſon. The life of an individual ſometimes depends upon the reſult of a chemical teſt, many of which are very ambiguous. How very neceſſary, therefore, it is to be able to detect the preſence of very ſmall portions of this ſubſtance by ſome method which will be ſo ſimple and certain as to be uſed by any individual. We ſhall here give the common methods which have been recommended by different chemiſts.

If the fluid containing the corroſive ſublimate be colourleſs and clear, ſuch as water, ſulphuretted hydrogen gas paſſed through the fluid will change it to firſt a yellow colour, which gets deeper, and if the quantity of ſublimate be conſiderable, it will become black. This gas may be obtained as follows. Heat a bar of iron to a bright red, and rub the heated part with a roll of ſulphur. A ſulphuret of iron will be formed, which will fall off in drops. Let this ſubſtance be put into a common phial, to which a cork muſt be fitted, through which is paſſed a bended glaſs tube. Then to one part of the ſulphuret of iron add one of ſulphuric acid, and five of water. Inſert the cork with its tube as quick as poſſible, and let the gas which eſcapes paſs through the fluid ſuppoſed to contain the ſublimate, which, if that ſubſtance be preſent, will change colour in a few minutes. It muſt be obſerved, that the ſame gas would give a yellow colour if the fluid contained arſenic. The latter, however, is more of a golden yellow, and remains permanent, while the former changes to a dark brown. Pure potaſh or lime water is an excellent teſt for the oxymuriat of mercury. When ſolutions of the above ſubſtances are dropped into a fluid containing the ſmalleſt portion of corroſive ſublimate, the potaſh produces a bright orange coloured precipitate, which is the peroxyd of mercury. The lime water produces a ſimilar precipitate, but rather more inclining to a brick-red colour.

A very ſenſible teſt for corroſive ſublimate was ſome time ago propoſed by Dr. Boſtock of Liverpool, which was the muriat of tin. When a few drops of a ſolution of tin in muriatic acid are added to any fluid containing the ſmalleſt portion of oxymuriat of mercury, a very conſpicuous milky whiteneſs inſtantly appears. This is occaſioned by the oxyd of tin ſeizing the exceſs of oxygen in the oxymuriat of mercury, by which a quantity of the oxyd of tin, or rather, perhaps, the ſubmuriat, is inſtantly ſet free, and at the ſame time the oxymuriat of mercury is converted into muriat, which is alſo precipitated. Hence this very conſpicuous phenomenon ariſes from the joint precipitation of the above ſubſtances. Senſible as this may be, it is not to be relied upon, except in the hands of very accurate obſervers. When muriat of tin is dropped in water, it becomes milky by the precipitation of the ſubmuriat of tin, even where no corroſive ſublimate is preſent. Hence, if more water be preſent with the ſuſpected matter, than will be calculated to keep the tin ſuſpended, the reſult will be ambiguous and uncertain.

From what has been ſaid of the properties of this ſalt, it will appear that any ſubſtance will form a teſt of ſalt which will either precipitate the oxyd, or deprive it of ſome of its oxygen. In the firſt caſe the high coloured red oxyd becomes very conſpicuous: in the ſecond, the oxymuriat of mercury is reduced to the ſtate of muriat, which renders the fluid turbid and milky, from the inſolubility of the latter ſubſtance.

The moſt ſatisfactory appearance of the preſence of corroſive ſublimate would be the mercury itſelf, ſince this ſalt is the only ſoluble muriat to be purchaſed in the ſhops. If the mercury be made to appear in its metallic ſtate, it may almoſt be deemed impoſſible for it to have originated from any other ſubſtance than the oxymuriat of mercury. Fortunately we have it in our power to recommend a method to the public which will anſwer this purpoſe completely. It is ſo ſimple as to be practiſed by any perſon unacquainted with chemiſtry, and it is ſo ſenſible, at the ſame time, that it is impoſſible to ſay how minute a quantity of mercury can be detached.

It is founded upon the principle by which the precipitation of one metal by another, under the influence of electricity, takes place. In order to make the apparatus as ſimple as poſſible, we ſhall uſe, in lieu of a piece of gold wire, a common wedding ring, and when a piece of zinc wire cannot be had, a piece of iron wire will do very well. Let the zinc or iron wire be bent into the ſhape of a parallelogram about two inches long, and about the width of the gold ring. Let this conſiſt of three ſides, two long ſides and one ſhort ſide, fide, that it may have the appearance of a fork or a ftaple. Tye the ends of the wire to the ring with a bit of thread, fo that the fame may be oppofite to each other, feparated by the diameter of the ring. When this is done, the ring and the wire, when laid upon a flat furface, will touch the furface in two places; the ring in one place, and the fhort fide of the parallelogram in another, the touching points being about two inches diftant: then take a flat piece of window glafs, or a fmall looking glafs, and lay it in a horizontal pofition, fo that any liquid dropped upon it may not run to any fide. This being done, prepare a fmall quantity of dilute fulphuric or muriatic acid, about four of water to one of acid, and alfo get fome of the liquid fuppofed to contain the corrofive fublimate. Let the dilute acid be dropped upon the plate, till it fpreads to the breadth of about one inch and a half. Then, at about half an inch diftance from it, let the fufpected liquid be dropped, till the peripheries of the two circles join. After this, let the apparatus above defcribed be fo laid, that the iron wire may touch the dilute acid, and the gold ring the other liquid. If the latter contain corrofive fublimate, the ring will become covered with mercury on the part which touches the liquid. This appearance will be fooner in taking place, as the quantity of corrofive fublimate is greater. When the liquid contains two parts of this fubftance, the mercury will be very perceptible upon the ring in five minutes from the time of the connection being made.

Mr. Chenevix, in afcertaining that corrofive fublimate was not oxymuriat of mercury, but merely muriat of mercury highly oxydated, has difcovered a falt which is truly the oxymuriat of this metal. By paffing a current of oxymuriatic gas through water, in which there was fome red oxyd of mercury, after a time the red oxyd became of a very dark brown colour, and part of it was diffolved. The liquor was then evaporated nearly to drynefs, and a mixed falt was obtained, confifting partly of corrofive muriat, and partly of another falt which cryftallized later than the former, and on being rediffolved and cryftallized appeared nearly pure. This falt, which has not been much examined, poffeffes the effential quality of an oxymuriat, in giving out vapours of oxymuriatic acid by the effufion of the fulphuric or any ftronger acid.

Phofphat of Mercury.—Phofphoric acid does not act upon mercury, becaufe of the great affinity of phofphorus for oxygen. This acid, however, combines with the oxyds of mercury, forming phofphat of mercury. The beft method of forming this falt is by adding phofphat of foda in folution to nitrat of mercury: the phofphoric acid leaves the foda to combine with the oxyd of mercury; the compound falling down in the ftate of white powder. It fhould be obferved, that if the phofphat of foda is not made from the acid which is obtained by burning phofphorus, the refult will not be correct; fince the acid obtained from bones is a fuper-phofphat of lime: and Mr. Dalton has lately found, that the fubftance at prefent ufed in medicine as phofphat of foda, is a triple falt, being a phofphat of foda and lime.

Phofphat of mercury becomes phofphorefcent when rubbed in the dark. Like the phofphat of lead, it affords phofphorus by diftillation with charcoal. It is faid to anfwer as a fubftitute for fome other mercurials in medicine. It appears from its analyfis to be a fuper-oxyphofphat: this, however, does not appear plaufible, from the manner of preparing it. If the nitrat of mercury be fully faturated with acid, the mercury cannot unite with more acid than will form a fimple phofphat, except the phofphat of foda be a fuper-falt, or that the phofphat of mercury on its formation, be refolved into fub and fuper-falts; both of which fall down together. If the folution of mercury employed in the preparation of the falt does not contain the fecond oxyd, the falt cannot be an oxy-falt, nor can any portion of it become fo, but at the expence of two falts being formed; the one confifting of the acid united to the protoxyd, as in the cafe of forming the muriat; and the other confifting of the acid united with the peroxyd, forming an oxy-falt. There is at prefent fo much ambiguity in the facts given of this falt, that we cannot be warranted at prefent in propofing any thing conclufive. The neutral phofphat with the protoxyd, if fuch a falt exift, will be as follows: $\frac{147 + 7 + 23}{23} = \frac{100}{13}$, or 13 acid, and 87 bafe. The oxyphofphat will be $\frac{147 + 21 + 23}{23} = \frac{100}{12}$, or 12 acid and 88 bafe. The fuper-oxyphofphat is $\frac{147 + 21 + 46}{46} = \frac{100}{21.5}$, or 21.5 acid, and 78 5 bafe. According to the analyfis of Braumcamp and Sigueira, it confifts of 28 5 acid, and 71.5 of the peroxyd. The fub-oxyphofphat of mercury, which in all probability may exift, will confift as follows: $\frac{(147 + 21) \cdot 2 + 23}{23} = \frac{100}{6.1}$, or 6.1 of acid, and 3.9 of peroxyd.

Fluat of Mercury.—Fluoric acid has no action upon mercury. When an alkaline fluat is added to a folution of nitrat of mercury, an infoluble powder falls down, which is the fluat of mercury. Nothing more is known of this falt.

Borat of Mercury.—This falt may, like the laft, be formed by adding borat of foda to nitrat of mercury, the boracic acid having no action upon the metal. It falls down in the form of infoluble powder, like the laft falt.

Carbonat of Mercury.—Carbonic acid does not act upon mercury. This falt is formed by adding carbonat of potafh to nitrat of mercury. The falt is precipitated in the ftate of powder of a white colour, and is known in medicine by the name white precipitate of mercury. According to the analyfis of Bergman, it confifts of 90.9 mercury, and 9.1 of oxygen and carbonic acid. By hypothefis it is $\frac{147 + 14 + 19}{19} = \frac{100}{11}$, or 11 of acid, and 89 of the fecond oxyd. When this falt is expofed to heat, the carbonic acid flies off, and leaves the yellow oxyd.

The precipitate formed by adding the carbonat of potafh to oxynitrat of mercury is feldom a true carbonat. At the moment it is precipitated, it appears of a beautiful white; but upon fhaking the mixture fome carbonic acid efcapes, and the precipitate affumes a yellowifh hue. It is therefore certain, that the precipitate becomes ultimately a fub-carbonat. If it were to remain a carbonat, no carbonic acid ought to efcape. The proportions under thefe circumftances are $\frac{2 \cdot (147 + 14) + 19}{19} = \frac{100}{5.5}$, or 5.5 of carbonic acid, and 94.5 of the yellow oxyd. The oxygen in this falt is 4.1 *per cent.* This, added to the acid, gives 9.6 of oxygen and acid together, which very nearly agrees with the analyfis of Bergman above given. Hence it will appear that this was the falt which he analyfed, and not the carbonat.

nat. The ſub-carbonat obtained from the nitrat, which gives the protoxyd, is perfectly white.

Acetat of Mercury.—The acetic acid does not act upon mercury; but it diſſolves its oxyds, forming ſeveral ſpecies of ſalts. When a ſolution of the acetat of potaſh is added to a ſolution of the nitrat of mercury, the acetic acid combines with the protoxyd, and is precipitated in the form of flat ſcaly cryſtals, reſembling boracic acid, which is the true acetat of mercury. If the oxynitrat be employed which contains the ſecond oxyd, in all probability a change takes place ſimilar to that in the formation of the muriat, by adding muriat of ſoda. The oxyd is equally divided into the prot and peroxyd, by which an acetat, with ſome ſub-oxyacetat, is formed, while a ſuper-oxyacetat will remain diſſolved. This ſalt is inſoluble in alcohol, and nearly ſo in water.

Oxyacetat.—This ſalt may be formed by diſſolving the peroxyd in the acetic acid. When evaporated it does not cryſtallize, but forms a yellow coloured maſs, which is deliqueſcent. When water is added to it, the ſalt is changed into a ſub-oxyacetat, which precipitates in the ſtate of a yellow powder, and a ſuper-oxyacetat, which remains diſſolved. When the oxyacetat is heated, the acetic acid deprives the mercury of ſome oxygen, and cryſtals of the acetat are formed.

Oxalat of Mercury.—Oxalic acid, as well as the other vegetable acids, has no action upon mercury. It combines with the oxyd of mercury, forming an oxalat which is nearly inſoluble in water. This ſalt turns black by the action of light; and, according to the authority of Klaproth, it detonates when heated. Dr. Thomſon thinks this ſalt a conſtituent of the fulminating mercury of Howard.

Tartrat of Mercury.—If tartrat of potaſh be added to a ſolution of nitrat of mercury, the tartrat of mercury will be precipitated in the ſtate of white powder. It is changed to a yellow colour by expoſure to light.

Citrat of Mercury.—This ſalt is ſcarcely ſoluble in water. It is decompoſed by diſtillation; the oxyd being reduced by the carbon and hydrogen of the acid.

The *Succinat of Mercury* is ſlightly ſoluble.

The *Benzoat of Mercury* is inſoluble in water: it ſublimes by heat, and is decompoſed by the ſulphuric, nitric, and muriatic acids.

The *Malat* of this metal is an inſoluble powder.

Pruſſiat of Mercury.—This ſalt may be formed by boiling the red oxyd of mercury with Pruſſian blue in water. It is ſoluble in water to a certain extent, and the ſolution affords cryſtals of a priſmatic form. It is generally employed to get pure pruſſic acid, by diſtillation with ſulphuric acid.

Arſeniat of Mercury.—When arſenic acid and mercury are heated together in a retort, the mercury is oxydized, and oxyd of arſenic is volatilized, leaving the arſeniat of mercury. This ſalt may alſo be formed by adding the arſeniat of potaſh to nitrat of mercury in ſolution. The arſeniat of mercury is precipitated in the form of yellow powder.

Molybdat of Mercury, with the protoxyd, is inſoluble, but ſoluble with the peroxyd, which forms an oxymolybdat.

Chromat of Mercury is formed by an alkaline chromat with nitrat of mercury. It falls down in the ſtate of powder of a purple colour. Several triple ſalts of mercury have been noticed by chemiſts.

Nitro-oxymuriat of Mercury has been pointed out by Berthollet. It is formed by adding a ſolution of muriat of ſoda to oxynitrat of mercury. A ſalt is obtained by evaporation in rhomboidal cryſtals. May not this ſalt be merely a mixture of muriat of ſoda and ſuper-oxymuriat of mercury cryſtallized together on account of the ſimilarity of their form?

Oxymuriat of Soda and Mercury.—This is no doubt the ſuper-oxymuriat of mercury cryſtallized with muriat of ſoda, ſince it is formed by adding four parts of ſuper-oxymuriat of mercury to one of muriat of ſoda.

Sub-oxymuriat of Mercury and Ammonia.—When ammonia is poured upon the ſuper-oxymuriat of mercury, the ammonia takes up as much of the acid as leaves the remainder in a ſtate of ſub-ſalt. The two ſalts fall down together in the ſtate of white powder. The analyſis of Fourcroy ſhews it to conſiſt of certain proportions of the two ſalts; which is 16 acid, 81 oxyd, and 3 of ammonia. This gives 14 of muriat of ammonia, and 86 of the ſub-oxymuriat of mercury.

This compound ſalt is ſoluble in muriatic acid. In this ſtate it has been called *ſal alembroth*. In modern nomenclature, it has been denominated the *ammoniaco-mercurial muriat.*

Tartrat of Potaſh and Mercury.—This ſalt is formed by boiling tho oxyd of mercury with ſuper-tartrat of potaſh. The oxyd of mercury takes the exceſs of acid from the ſuper-tartrat to form a tartrat. By evaporation the two cryſtallize together.

Mercury combines with the ſulphuret and ſuper-ſulphuret of hydrogen, forming black inſoluble precipitates. The firſt is called hydro-ſulphuret, and the ſecond a hydroguretted ſulphuret.

Mercury is very valuable in the arts on account of ſome of its phyſical properties, principally for conſtructing barometers and thermometers.

For the firſt of theſe uſes the mercury ſhould be perfectly free from air, which it mechanically contains in common with other liquids, and which leaves it when the preſſure of the atmoſphere is removed. If, therefore, a barometer be made with mercury not freed from air, the column conſtituting the barometer will be depreſſed by the ſpring of the air which riſes into the upper part of the tube.

In order to purify mercury for the uſe of barometers and thermometers, it ſhould firſt be diſtilled in a retort of iron or Wedgewood ware. After this, however, it does not acquire its greateſt degree of fluidity, nor does it appear perfectly bright. This is principally owing to its being mechanically mixed with ſome oxyd of mercury. This is completely removed by digeſting it a little time with very dilute nitric acid. It becomes very brilliant and fluid. It muſt now be well waſhed with water, and the water dried up clean. After this it muſt be boiled in the tube it is intended to fill. If, while the tube is hot, it be placed, with the open end upwards, under the receiver of an air-pump, and is ſhaken frequently, a ſtill greater quantity of air is ſet free, and the mercurial column will ſtand higher in conſequence. We can have little dependence upon the abſolute height of the barometer, where this precaution is not taken. See Barometer and Thermometer.

Mercury is extenſively uſed in gilding, but has been productive of great miſchief to the workmen, from their inhaling the vapour which muſt of neceſſity be formed.

We have already given ſome account of this proceſs, ſufficient to ſhew, that if the mercury, when it evaporates, could be forced into ſome channel, without coming near to the workman, and without mixing with the ſmoke of the chimney, its deleterious effects would not only be avoided, but the greateſt part of the mercury would be ſaved, which would be of very great importance to the proprietors of ſuch manufactures as employ gilding on a large ſcale.

We have long been in poſſeſſion of the means of remedying

ing this evil, at an expence which would speedily be reimbursed by the saving of the mercury alone.

The furnace to produce the heat should be a common air-furnace, but so constructed as to contain a vessel of the nature, though not of the shape, of a muffle. Its form would be determined by the size and figure of the articles to be gilt. It should have such an opening in front, and be so spacious within, as just to allow the workman to turn the articles freely about during their exposure to evaporate the mercury. The upper part of the muffle should have a chimney connected with it of earthenware, of the same kind as that of the muffle. This chimney must pass for some distance up the main chimney, in order to be heated for the purpose of rarefying the enclosed air, to cause a rapid current. The earthen chimney, being carried about a yard high, should now branch out of the main chimney, and be continued with an iron pipe to the height of about twenty feet. This iron pipe should communicate with the earthen tube, by a perpendicular branch from it, within about six feet of the bottom of the former, so that one part of the iron pipe ascends to the height of twenty feet, and the other descends about six feet into a cistern of water. By this means a current of air will constantly be entering the mouth of the muffle, which must of necessity carry with it the vapour of mercury, unmixed with any other extraneous matter. The mercurial vapour will be condensed long before it reaches the top of the iron tube, and will fall into the cistern of water below. The water will prevent the oxydation of the mercury between the times of removing it.

Another advantage attending this apparatus, will be the uniform heat to which the evaporable surface will be exposed. The greatest heat of the fire will be much less in this contrivance, and consequently less annoying to the face and eyes of the workman. This evil, however, may be still made less, by interposing a screen of glass between the face and the fire.

MERCURY, or *Hydrargyrus*, in the *Materia Medica*. This fluid, supposed by the Greeks to be poisonous and corrosive, was introduced into medicine, by the Arabians, as an ingredient in external applications, against different cutaneous maladies. The practice was followed by some physicians in Europe towards the end of the thirteenth century; but was not established or looked upon in general to be safe, till about the beginning of the sixteenth, when the venereal distemper, then lately received from America, was found to yield to mercurial applications alone: and now also the internal use of mercury began to be ventured on, in this and in other diseases. Crude and fluid mercury taken internally produces no effect on the body; because the adhesion of its integrant parts to each other hinders their division and distribution, or solution, without which it cannot have any effect. In its crude state, therefore, it does nothing but load the stomach and intestines. It falls downwards by its weight, and goes out of the body with the fæces, in the same state in which it entered. Hence some have been induced to give a pound or more in violent constipations, in order to open obstructions that had resisted the common methods of cure by purgatives, relaxants, and emollients. But the practice has been attended with no remarkable success.

Dr. Dover, in his "Physician's Legacy to his Country," having recommended crude mercury or quicksilver as a most beneficial medicine for several diseases, it had for some time a great run in London, which occasioned the writing a great many pamphlets for and against it. Dr. Cheyne also greatly recommends this medicine in his treatise, entitled "The Rational Method of curing Diseases."

The authors of the Medical Essays of Edinburgh assure us, that though some they knew had taken an ounce or two of crude mercury each morning for several weeks, yet they were not apprized of any instance of its increasing any of the sensible evacuations; but they have been told, that some who used it thus, had passed some of it with their urine, and that the hands of others, taking this medicine, had tinged their snuff-boxes, &c.

But we have an account of the effects of crude mercury on a person who had the advice of his physician for the taking it, in a remarkable case, recorded in the Philosophical Transactions, about the time when Dr. Dover had brought it into such general use; and as the effects of it, in this case, may serve to caution people as to the use of it, it may be proper to give the substance of it, which is this: a person had long been subject to great difficulty in going to stool, for which he at length took several ounces of crude mercury at different times, but without relief. Upon the opening of the abdomen there issued out a great quantity of wind, before the stomach or guts were wounded. The stomach was empty, and its inner coat violently inflamed. The small guts were, in many places, fouled with a black powder, resembling æthiops mineral, and in several parts of them were found small globules of quicksilver. The black powder was doubtless the quicksilver altered into a sort of æthiops in the body. The colon was inflamed and distended, and contained six quarts of liquid excrement, among which was a great deal of crude mercury, and of the same black powder. This gut also was inflamed on the outside, and had formed an abscess where it adhered to the omentum; the other guts in contact with this part also shared this disorder. On the lower part of the colon the coats became schirrous, and the passage was very small. Some of the valves were also become schirrous, and obstructed the passage, and a small plum-stone was found buried in the villose coat of this intestine. This had also formed a small abscess, which discharged itself into the pelvis. What part of these symptoms was owing to the taking the quicksilver is easily seen, and such effects may be guarded against for the future, by observing the state of the patient before it is given. Phil. Transf. N° 442. p. 295.

But when mercury is much divided, so that its molecules cannot again unite and form fluid mercury by the interposition of proper substances, it operates with great power, and extends its action through the whole habit. In these forms, whether taken internally, or introduced into the blood from external applications, it seems to liquefy all the juices of the body, and may be so managed as to promote excretion through all the emunctories. The salutary effects of mercurials have, in many cases, very little dependence on the quantity of sensible evacuation. Venereal maladies and chronical distempers, proceeding from a viscidity of the humours and obstructions of the small vessels, are often successfully cured by mercurials taken in such doses as not to produce any remarkable discharge: especially if assisted by diaphoretics, and a warm diluting regimen. In this view, camphor, and the resin or extract of guaiacum, are frequently joined to the mercury; and to the more active preparations, a little opium; which not only promotes the diaphoresis, but prevents the mercury from irritating the first passages, and running off by the grosser emunctories. Mercurials are always pernicious in the true scurvy, and in constitutions inclined to this disease, whose humours are disposed to a putrescent state; and a long continued use of mercury colliquates the whole mass of blood, and tends to weaken the nerves, so as to bring on tremors and paralyses. Mercurials are destructive to insects, perhaps of every kind: they are sometimes given internally against worms; and Van

Helmont ſays, that water in which mercury has lain ſome time, though inſipid, will deſtroy worms; and Mr. Boyle ſeems to recommend it as an innocent and uſeful coſmetic. Works Abr. vol. iii. p. 345.

Although mercury in its native metallic ſtate is a perfectly inert ſubſtance with reſpect to any operation on the animal ſyſtem, it may be rendered active by ſome changes in its chemical ſtate, or ſome addition to its ſubſtance. When rendered thus active, it ſeems to be a ſtimulus to every ſenſible and moving fibre of the body to which it is applied; and it is particularly a ſtimulus to every excretory of the ſyſtem, to which it is externally or internally applied. Beſides its noted effects upon the excretories of the ſaliva, it ſeems to operate upon the whole of thoſe of the alimentary canal. It proves often diuretic; and Dr. Cullen ſays, that he has met with particular proofs of its reaching and acting upon the organs of perſpiration. Whilſt it is known to operate more upon certain excretions than upon others, it may be preſumed, that when any tolerable quantity is thrown into the body, it is in part diſtributed over the whole; and therefore its medicinal effect is, that it is the moſt univerſal aperient and deobſtruent known. Dr. Cullen, however, contends, in oppoſition to the common opinion, that the effects of its producing evacuations depend entirely upon the ſtimulus given to the excretories, and not at all to any change produced in the ſtate of the fluids. Upon many occaſions of mercury thrown into the body very largely, this author has found no difference in the appearance of the ſtate of the blood drawn out of the veins. From the ſtimulus given by mercury to the whole ſyſtem, he has always found the blood putting on the ſame appearance that it does in inflammatory diſeaſes, nor has he obſerved any circumſtance that implies any diminution of its ordinary conſiſtence. Although it has been the common opinion, that mercury diminiſhes the conſiſtence of the blood, and very much increaſes its fluidity, no evidence or proof of this as a fact, known to Dr. Cullen, has been produced; and he thinks, that it has been taken up upon miſtaken facts, and ſupported by a theory which is without foundation. Upon the whole, our author concludes, that the chief effects of mercurial medicines are to be aſcribed to their general ſtimulus of the ſyſtem, and eſpecially to their ſtimulating the various excretories of it. Concerning its medical effects in the diſeaſe to which it has been moſt generally and moſt efficaciouſly applied, we refer to the article LUES VENEREA. But the various operations of mercury are modified, in a very remarkable degree, by the different preparations of it which have been propoſed and employed. In conſequence of the changes which it undergoes by its numerous preparations, ſo that it is become one of the moſt conſiderable articles in the chemical pharmacy, and a remedy of the moſt extenſive application, it is not only a powerful ſtimulant, but it enters into the circulation, quickens the vaſcular action, and excites powerfully the whole of the glandular ſyſtem, increaſing all the ſecretions and excretions. Hence it happens, that its various preparations produce different effects, operating ſometimes as ſtimulants, aſtringents, cathartics, or emmenagogues, and locally as errhines; and hence it becomes uſeful in a great variety of diſeaſes; ſuch as febrile affections, ſpaſms, cachectic diſeaſes, glandular obſtructions, and cutaneous eruptions. Since Paracelſus, counteracting ancient authority and practice, evinced that it might be exhibited internally, not only with ſafety, but with advantage, during a period of almoſt 300 years, experience has fully ſanctioned its uſe; and as Mr. Pearſon juſtly obſerves, "not one medicine beſides, derived from the animal, vegetable, or mineral kingdom, has maintained its credit, with men actually employed in extenſive practice, during a tenth part of that period." Although it is a medicine capable of being abuſed, to the diſappointment of the patient, and to the injury of the conſtitution, yet under the direction of cautious and judicious practitioners, it may rank as one of the moſt uſeful of the articles of the Materia Medica.

The chemical changes which have been propoſed, in order to render mercury active and uſeful, have been many and various; but Dr. Cullen, in his "Materia Medica," refers them to four heads; 1ſt, by being converted into vapour; 2dly, by calcination; 3dly, by triture with viſcid fluids; and, 4thly, by being combined with acids of different kinds. The firſt mode of employing mercury, may perhaps (he ſays) be the beſt adapted to ſome local complaints; but its application to the whole body is attended with ſo much hazard and uncertainty in the adminiſtration, as hardly ever to be an eligible practice. The preparation by calcination is not, as had been formerly ſuppoſed, of any peculiar power or advantage; and is therefore as he believes, little employed in the preſent practice; this operation ſerving merely to put the mercury in a condition to be acted upon by the acids of the ſtomach, and the preparation not differing from others made by a combination with acids. The preparations by triture ſeem to be milder than thoſe formed by a combination with acids; but imperfect triture renders the practitioner often uncertain in their uſe. The triture with unguinous ſubſtances gives the advantage of its being introduced by unction upon the ſkin; and when it has been properly prepared, and is properly adminiſtered, it affords a mode of introducing mercury, which is often leſs liable to purging, and therefore more convenient than the employment of the ſaline preparations. Theſe latter are different according to the acid employed.

Thoſe made by the vegetable acid are milder and more manageable than thoſe formed with any of the foſſil acids. Of theſe, the combination with the muriatic acid, when the acid is in its full proportion to the mercury, as it is in the corroſive ſublimate, is certainly more active and powerful than any other ſaline preparation. The uſe of it has been often convenient and effectual; but its operation is ſo different in men of different conſtitutions, that the employment of it requires much management and diſcretion. It is rendered much milder in the preparation of the Mercurius dulcis, which has given occaſion to the frequent employment of this, which, according to Dr. Cullen, does not ſeem to be a very eligible preparation. It does not ſeem to be ſo readily diffuſible in the ſyſtem as many others, becauſe it is more ready than many others to operate upon the inteſtines, and run off by ſtool. This may give it ſome advantages for its being combined with purgatives; but for that reaſon it is leſs fit for being employed to act upon the ſalivary glands, or upon the other excretions of the ſyſtem. Dr. Duncan, in the "Edinburgh New Diſpenſatory," has given a table of officinal preparations of mercury, of which Mr. A. T. Todd has availed himſelf in the valuable "London Diſpenſatory," lately publiſhed. We ſhall take the liberty of inſerting his table for the ſatisfaction of our medical readers, recommending the work itſelf to their peruſal.

Officinal Preparations of Mercury.

I. By diſtillation to purify the metal.
  1. Hydrargyrus purificatus. L. D.

II. By trituration; (ſuboxidized).

a. With animal fat.
  2. Unguentum Hydrargyri fortius. L. Ung. Hydrargyri. D.
  3. Unguentum Hydrargyri. E.

4. Ungu-

4. Unguentum Hydrargyri mitius. L. D.
5. Linimentum Hydrargyri. L.
6. Emplaftrum Ammoniaci cum Hydrargyro. L. D.
——— - Hydrargyri. L. E.

b. With faccharine fubftances.
7. Pilulæ Hydrargyri. L. E. D.

c. With carbonate of lime.
8. Hydrargyrus cum Cretâ. L. D.

d. With carbonate of magnefia.
9. Hydrargyrum cum Magnefiâ. D.

III. By the action of heat and air: (oxidized).
10. Hydrargyri Oxydum rubrum. L. Oxydum Hydrargyri. D.

IV. By the action of acids.

a. With fulphuric acid; (fuboxidized).
11. Subfulphas Hydrargyri flavus. E. Oxydum Hydrargyri fulphuricum. D.

b. With nitric acid; (fuboxidized).
12. Unguentum Hydrargyri nitrati. L. E. Unguentum Supernitratis Hydrargyri. D.
13. Unguentum Nitratis Hydrargyri mitius. E.
——— ——— (oxidized).
14. Hydrargyri Nitrico-oxydum. L. Oxidum Hydrargyri rubrum per Acidum nitricum. E. Oxydum Hydrargyri nitricum. D.
15. Unguentum Hydrargyri nitrico-oxydi. L. Unguentum Oxidi Hydrargyri rubri. E. Unguentum Subnitratis Hydrargyri. D.

c. With muriatic acid.
† fublimated; (oxidized).
16. Hydrargyri Submurias. L. E. Submurias Hydrargyri fublimatum. D.
17. Pilulæ Hydrargyri Submuriatis. L.
——— ——— (oxidized and acidified).
18. Oxymurias Hydrargyri. L. Murias Hydrargyri. E. Murias Hydrargyri corrofivum. D.
19. Liquor Hydrargyri Oxymuriatis. L.
†† precipitated; (oxidized).
20. Submurias Hydrargyri præcipitatus. E. D.

d. With acetous acid; (fuboxidized).
21. Acetis Hydrargyri. E. Acetas Hydrargyri. D.

V. By precipitation with earths and alkalies from acid folutions.

a. By lime-water from the nitric folution; (fuboxidized).
22. Hydrargyri Oxydum cinereum. L.

b. By ammonia from the nitric folution; (fuboxidized).
23. Oxydum Hydrargyri cinereum. E. Pulvis Hydrargyri cinereus. D.

c. By ammonia from the muriatic folution; (oxidized).
24. Submurias Hydrargyri ammoniatum. D. Hydrargyrus Præcipitatus albus. L.
25. Unguentum Submuriatis Hydrargyri ammoniati. D. Ung. Hydrargyri Præcipitati albi. L.

VI. Combined with fulphur.

a. By trituration.
26. Sulphuretum Hydrargyri nigrum. E. D.

b. Sublimated.
27. Hydrargyri Sulphuretum rubrum. L. D.

We fhall here fubjoin a more particular account of thefe different preparations, as they occur in the London, Edinburgh, and Dublin difpenfatories, annexing to the modern names the appellations by which they have been diftinguifhed in former, now fuperfeded, nomenclatures.

Hydrargyrus purificatus. Argentum vivum purificatum, P. L. 1745.

Rub together 6lbs. of mercury, by weight, with 1lb. of iron filings, and diftil the mercury from an iron retort, by the application of heat to it. The E. D. directs four parts of mercury, and one part of filings of iron, to be rubbed together and diftilled from an iron retort. The Dub. D. procures it by diftilling off flowly 4lbs. from 6lbs. of mercury.

Hydrargyri Acetis, acetite of mercury, is prepared, according to the E. D., by mixing 3 oz. of purified mercury with 4½ oz. or a little more than may be neceffary for diffolving the mercury, of diluted nitrous acid; and having diffolved 3 oz. of acetite of potafs in boiling water, by adding to this folution, while hot, the former, and mixing them by agitation. When the mixture has been fet afide to cryftallize, the cryftals are wafhed in a funnel with cold diftilled water, and then dried with a gentle heat.

Hydrargyri Acetas, acetate of mercury, is obtained, according to the directions of the Dub. D., by adding three fluid-ounces of diluted nitrous acid to 3 oz. of purified mercury, and digefting, when the effervefcence ceafes, upon hot fand, for the complete diffolution of the metal: then mixing this folution with eight pints of boiling diftilled water in which 3 oz. of acetate of kali have been previoufly diffolved, and paffing the mixture immediately through a double linen cloth: afterwards cooling it that cryftals may be formed, wafhing thefe with cold diftilled water, and drying them upon paper with a very gentle heat.

All the veffels in thefe two proceffes muft be of glafs.

The acetate of mercury is antifyphilitic, and alterative; but it is fcarcely ever ufed, except as an active ingredient in Keyfer's pills. In fome cutaneous affections a folution of it, in the proportion of two grains in f.℥ii of rofe water, is externally applied. The internal dofe is 1 gr. night and morning.

Hydrargyri oxymurias, oxymuriate of mercury, Hydrargyrus muriatus, P. L. 1787, Mercurius corrofivus fublimatus, P. L. 1745, P. L. 1720, is prepared, according to the L. D. 1809, by boiling 2lbs. by weight of purified mercury with 30 oz. by weight of fulphuric acid in a glafs veffel until the fulphate of mercury is left dry: then, rubbing this, when cold, with 4lbs. of dried muriate of foda, in an earthenware mortar, and afterwards fubliming it in a glafs cucurbit, gradually increafing the heat. The corrofive fublimate is denominated *Murias hydrargyri,* or muriate of mercury, in the E. D. and prepared much in the fame manner. In the Dub. D. it is denominated *Murias hydrargyri corrofivum.* It is prepared by diffolving 2lbs. of purified mercury in 3lbs. of fulphuric acid, gradually increafing the heat until the matter becomes almoft dry; when cold, rub it with 2½lbs. of dried muriate of foda in an earthenware mortar, and then fublime it, in a proper veffel, with a gradually increafed heat. Mr. Chenevix found, that if a bit of copper be put into a folution of corrofive fublimate, a white powder ufually falls to the bottom, and that powder is "calomel." When wafhed, it does not contain an atom of copper, nor of corrofive fublimate.

This falt is a powerful ftimulant and alterative; and in large dofes it is one of the moft violent of the metallic poifons. It was formerly much extolled as an antifyphilitic; but Mr. Pearfon obferves, that even in checking the progrefs of the fecondary fymptoms, relieving venereal pains, and healing ulcers of the throat, it never confers permanent benefit.

It is faid to be ufed with greater advantage in old ulcers, chronic rheumatifm, and cutaneous difeafes, particularly *lepra.* (See LEPROSY.) The fenfible operation of this falt is by urine, but fometimes it occafions the moft violent naufea, griping, and purging; in which cafe it fhould be combined with opium; and during the ufe of it, it is neceffary to take fome mucilaginous fluid, in order to allay its irritation. It is alfo ufed

ufed as an external application. The dofe is from ⅛th to ¼th of a grain, twice a day, formed into a pill with a crumb of bread or extract of poppies. Van Swieten brought this falt into more general ufe for the cure of venereal maladies: he diffolves a grain of the fublimate in 2 oz. of proof fpirit, but rectified fpirit diffolves it more perfectly, and gives of this folution from one to two fpoonfuls twice a day, continuing the medicine fo long as any of the fymptoms remain, with low diet, and plentiful dilution. There are many inftances in the London Med. Obf. and Enq. of the fuccefs of this method.

Hydrargyri oxymuriatis Liquor, folution of oxymuriate of mercury, is prepared by diffolving eight grains of oxymuriate of mercury in fifteen fluid-ounces of diftilled water, and adding to it a fluid-ounce of rectified fpirit. This folution is directed (P. L. 1809) in order to facilitate the adminiftration of divifions of the grain of this active medicine. Each fluid-drachm contains $\frac{1}{16}$th of a grain of the falt. This may be given as an antifyphilitic in dofes of from f.ʒfs to f.ʒij, in f.℥ij of linfeed infufion, or water and fyrup, and in more minute dofes, when its effects as an alterative only are required. As a local application, this folution diluted with two parts of water forms an ufeful gargle in venereal fore-throat, and without dilution it ferves as a gargle for breaking the abfcefs in cynanche tonfillaris, when fuppuration takes place. Diluted with an equal quantity of water, it is employed as a wafh againft tetters and pfora; and very largely diluted, it may be ufed as an injection in gonorrhœa, or given in the form of enema, when the ftomach will not bear it. This fublimate is a violent efcharotic, and eats away proud flefh: half a drachm of it diffolved in a pint of lime-water turns it yellow; it is then called "phagedænic water," and is ufed to wafh ulcerous and tetterous eruptions. A ftrong folution, made by boiling the fame quantity of powdered fublimate with equal its weight of alum in a pint of common water, until half the liquor is wafted, is the "alluminous water" applied to the fame purpofe.

Hydrargyri fubmurias, fubmuriate of mercury, Calomelas, Hydrargyrus muriatus mitis, P. L. 1787, Mercurius dulcis fublimatus, P. L. 1745, Aquila alba, Manna metallorum, Sublimatum dulce, is prepared, according to P. L. 1809, by rubbing together 1lb. of oxymuriate of mercury with 9 oz. by weight of purified mercury, until the metallic globules difappear, then fubliming, taking out the fublimed mafs, pulverizing it, and fubliming it in the fame manner twice more fucceffively; and, laftly, bringing it into the ftate of very fine powder, by the fame procefs which is directed for the preparation of chalk. A very elegant and ufeful modification of this procefs has lately been adopted by Mr. Howard, chemift, who fublimes the fubmuriate into water, with the vapour of which it mixes as it arifes in its gafeous form, and fubfides at once as a fine impalpable precipitate to the bottom of the water. Formerly preparations of mercury analogous to this were diftinguifhed according to the number of fublimations they had undergone. After three fublimations it was mercurius dulcis, after fix, calomelas, and after eight, panacea mercurialis; but, according to Beaumè, a fmall portion of oxymuriate is formed by each of thefe repeated fublimations, probably from the abforption of oxygen by the heated preparation from the air of the veffels, and hence no advantage, but rather the contrary, muft arife from an increafed number of the operations. The Pharmacopeia of 1745 had fix fublimations; that of 1787, as the directions feem to exprefs it, five; and now they are reduced to three, which are, in fact, fully fufficient, efpecially with that fubfequent application of water which the mode adopted for reducing it to a fine powder requires.

Hydrargyri fubmurias, five *Calomelas*, Edinb. D. Submuriate of mercury, or calomel; is obtained by rubbing together 4 oz. of muriate of mercury pulverized in a glafs mortar with 3 oz. of purified mercury, in a glafs mortar with a little water, to prevent the acrid powder from rifing, until the mercury be extinguifhed; putting the dried powder in an oblong phial, one-third full, and fubliming it in a fand-bath. When the fublimation is completed the phial is broken, and the red powder round its bottom, and the white at its neck, are rejected; the reft of the mafs is fublimed, and reduced to a fine powder, which is, laftly, to be well wafhed with boiling diftilled water.

Hydrargyri, Submurias fublimatum, five *Calomelas*, Dub. D. is prepared much in the fame manner with that of the Lond. Pharmac. The final trituration and levigation are intended to feparate any corrofive muriate that may have been formed; and in order to afcertain this, the Dublin college prefcribes the following teft; the fublimed matter is pulverized and repeatedly wafhed with diftilled water, until the folution poured off, no longer lets any fediment fall on the addition of a few drops of carbonate of kali.

Calomel is the moft ufeful and the moft frequently employed of all the preparations of mercury. It is antifyphilitic, antifpafmodic, alterative, deobftruent, purgative, and errhine. As a remedy in fyphilis, it can be fully confided in, when its difpofition to run off by the bowels is counteracted by opium; and in the fame ftate of combination it is alfo found efficacious in feveral convulfive affections, as epilepfy, trifmus, and tetanus; and in that fpecies of fpafmodic ftricture which occurs in virulent gonorrhœa. As an alterative and deobftruent, it is employed with advantage in cutaneous eruptions, as lepra, fcabies, and pfora, in which cafes it is combined with antimonials and guaiacum; and in hepatitis, and glandular obftructions; in dropfies it affifts the action of fquill and foxglove; and as a purgative it may be employed with fafety in almoft every form of difeafe not attended with vifceral inflammation, or where there are not great irritability and delicacy of habit. Calomel, however, does not act with certainty as a purgative even in large dofes, and hence it is generally combined with fcammony, jalap, or fome other active cathartic. The ufual dofe to affect the habit and produce ptyalifm is from gr. j to grs. ij, in a pill with opium, given night and morning; and from grs. iij to grs. viij act in general as a purgative: but in fome complaints, as yellow fever and croup for example, in which it is fuppofed to exert a fpecific effect, this dofe has been repeated every two or three hours, until upwards of 100 grains have been taken in a very fhort fpace of time.

On account of its infolubility and great fpecific gravity, it can be given only in the form of pills.

Hydrargyri Submurias precipitatus, precipitated fubmuriate of mercury, Edinb. is prepared by mixing 8 oz. of purified mercury with the fame quantity of diluted nitrous acid, and towards the end of the effervefcence digefting with a gentle heat, the veffel being frequently fhaken; at the fame time let 4½oz. of the muriate of foda be diffolved in 8lbs. of boiling water; and to this let the other folution be added while it is warm, and let them be mixed very quickly together. After the precipitate has fubfided, pour off the faline fluid, and wafh the fubmuriate of mercury by frequent affufions of warm water, which are to be poured off each time after the precipitate fubfides, until the water comes off taftelefs.

Hydrargyri Submurias precipitatum is obtained by pouring five fluid-ounces of diluted nitrous acid on 7 oz. of purified mercury in a glafs veffel, and at the termination of the effervefcence digefting with a gentle heat for fix hours, with frequent agitation. The heat fhould then be fomewhat raifed raiſed that the ſolution may boil a little, which being poured off from the reſidual mercury, ſhould be quickly mixed with 10lbs. of boiling water, in which 4 oz. of muriate of ſoda have been previouſly diſſolved; the ſubſiding powder is waſhed with warm diſtilled water, as long as the fluid poured off from it yields a precipitate on the addition of a few drops of the ſolution of ſubcarbonate of kali; and laſtly, it is to be dried. In reference to theſe proceſſes of the two colleges, we may here note, that Mr. Murray has aſcertained, that the quantity of mild muriate obtained from a ſolution of ℥j of mercury in the diluted nitric acid in the cold is a little more than ℥j; while from the ſame quantity diſſolved with the application of heat, the precipitate did not exceed ℥ſs, while the liquor held diſſolved much more corroſive muriate than the other. Hence it may be inferred, that the greateſt proportion of pure mild muriate of mercury by precipitation may be obtained, by preparing the nitrat ſlowly, and without the aid of heat, which ought not to be employed in any part of the proceſs.

The properties of this ſubſtance are eſſentially the ſame with thoſe of common calomel, and therefore it may be regarded as ſuperfluous.

Hydrargyrus precipitatus albus, white precipitated mercury, Calx hydrargyri alba, P. L. 1787, Mercurius precipitatus albus, P. L. 1745, is prepared, according to the directions of the London college, P. L. 1809, by firſt diſſolving ¼lb. of muriate of ammonia, and then the ſame quantity of oxymuriate of mercury, in four pints of diſtilled water, and adding to it half a pint of the ſolution of ſubcarbonate of potaſs; then waſhing the precipitated powder until it becomes taſteleſs, and afterwards drying it.

Hydrargyri Submurias ammoniatum, ammoniated ſubmuriate of mercury, Dub. is obtained by adding to the fluid which has been poured off from the precipitated ſubmuriate of mercury a quantity of water of cauſtic ammonia ſufficient to precipitate the whole of the metallic ſalt; then waſhing the precipitate with cold diſtilled water, and drying it upon bibulous paper. This preparation is only uſed, in combination with lard, as an ointment for the cure of the itch, and ſome other cutaneous eruptions. See Unguentum *Hydrargyri præcipitati albi.*

Hydrargyrus cum Creta, mercury with chalk, Mercurius alkalizatus, P. L. 1745, is prepared by rubbing together 3 oz. by weight of purified mercury with 5 oz. of prepared chalk, until the metallic globules diſappear. As this preparation is milder than any other mercurial one, and does not ſo eaſily act upon the bowels, it is very much uſed by many practitioners. It appears to be ſlightly oxydized by the trituration, as it contains, according to Fourcroy, only $\frac{4}{100}$ of oxygen.

Hydrargyrum cum Creta, mercury with chalk, of the Dublin college, is prepared in the ſame manner as the mercury with magneſia, employing precipitated chalk inſtead of magneſia. This ſubſtance is alterative, and occaſionally preſcribed in tinea capitis, and other cutaneous affections; but it merits very little attention. The doſe may be from 5 gr. to ℈ſs, given twice a day, mixed in any viſcid ſubſtances.

Hydragyrum cum magneſia, mercury with magneſia, of the Dublin college, is prepared by triturating an ounce of mercury with the ſame quantity of manna in an earthen mortar, adding as many drops of water as will give to the mixture the thickneſs of ſyrup, and continuing the rubbing until the metallic globules diſappear; then adding, whilſt the trituration is continued, a drachm of magneſia, and after the whole is well mixed, a pint of hot water, agitating the mixture. When it has remained ſome time at reſt, that the ſediment may ſubſide, decant from it the fluid, repeat the waſhing a ſecond and a third time, that the whole of the manna may be removed; and add the remainder of the magneſia to the ſediment, while it is ſtill moiſt: and laſtly, dry the powder upon bibulous paper. The addition of the manna in this and the former proceſs is intended only to facilitate the oxydizement of the mercury; and it is afterwards removed by the ſubſequent waſhings, ſo that the product remains a grey or black oxyd of mercury mixed with magneſia. This preparation is of no great importance.

Hydrargyri nitrico-oxydum, nitric oxyd of mercury, Hydrargyrus nitratus ruber, P. L. 1787, Mercurius corroſivus ruber, P. L. 1745, Mercurius precipitatus corroſivus, P. L. 1720, is prepared by the directions of the Lond. Pharm. by mixing in a glaſs veſſel 3lbs. by weight of purified mercury, 1½ lb. by weight of nitric acid, in two pints of diſtilled water, and boiling the mixture in a ſand-bath until the mercury being diſſolved and the water evaporated, a white maſs remains. Rub this into powder, and put it into another ſhallow veſſel, then apply a moderate heat, and raiſe the fire gradually until the red vapour ceaſes to ariſe. The component parts of this oxyd are, according to Fourcroy, mercury 92, and oxygen 8; according to Chenevix, mercury 85, oxygen 15.

Hydrargyri Oxydum rubrum per acidum nitricum, olim, *Mercurius precipitatus ruber*, Edinb. red oxyd of mercury by nitric acid, formerly red precipitate of mercury. Diſſolve a pound of purified mercury in 16 oz. of diluted nitrous acid; and evaporate the ſolution over a gentle fire to a dry white maſs, which being rubbed to a powder, is to be put into a glaſs cucurbit, and covered with a thick plate of glaſs: then adapt a capital to the veſſel, and having placed it in a ſand-bath, let the contained matter be roaſted with a fire gradually raiſed until it paſs into very red ſmall ſcales.

Hydrargyri Oxydum nitricum, Dub. nitric oxyd of mercury. Mix 10 oz. of purified mercury, and ten fluid-ounces of diluted nitrous acid in a glaſs, and diſſolve the mercury with a gradually raiſed heat: then increaſe the fire until the reſiduary matter in the bottom of the veſſel be converted into red ſcales.

Nitric oxyd of mercury is ſtimulant and eſcharotic. It is merely uſed externally, when rubbed into a fine powder, as a ſtimulant to old ſores, and for deſtroying fungus. As a powder, in the proportion of gr. ſs. to grs. iv of ſugar, it is blown into the eye to remove ſpecks in the cornea; and formed into an ointment with lard, it is an uſeful application to ulcerations of the eye-lids, and to chancres. See Unguentum *Hydrargyri nitrico-oxidi.*

Hydrargyri oxydum rubrum, red oxyd of mercury, Hydrargyrus calcinatus, P. L. 1787, Mercurius calcinatus, P. L. 1745, is prepared by pouring *e. g.* 1lb. by weight of purified mercury into a glaſs matraſs with a very narrow mouth and broad bottom: apply a heat of 600° to this veſſel, without ſtopping it, until the mercury has changed into red ſcales; then reduce theſe to a very fine powder. The whole proceſs may probably require an expoſure of ſix weeks.

Hydrargyri oxydum, Dubl. oxyd of mercury, is obtained by taking any quantity of purified mercury, and proceeding as in the laſt article.

According to Lavoiſier 100 parts of this oxyd contain 7 of oxygen; Fourcroy makes the proportion of oxygen 8, and Chenevix, 15 parts.

This is a very active preparation of mercury, and has been employed by ſome eminent practitioners, *e. g.* John Hunter, as an internal remedy in ſyphilis. See Lues Venerea. Its effects, however, are violent, ſo that it is now ſcarcely ever

ever employed internally, or as an antiſyphilitic. The doſe may be gr.j combined with gr.ſs of opium, in the form of pill, night and morning. It is chiefly uſed as an external ſtimulant and eſcharotic in the ſame caſes as the nitric oxyd; being previouſly rubbed to a fine powder, and either ſprinkled over the ulcers, or united with lard, and applied as an ointment.

Hydrargyri oxydum cinereum, grey oxyd of mercury, is formed, according to the inſtructions of the Lond. Pharm., by boiling an ounce of ſubmuriate of mercury in a gallon of lime-water, conſtantly ſtirring until a grey oxyd of mercury is ſeparated; waſh this with diſtilled water, and then dry it. The ſame preparation of the Edinb. Diſp. is formed of four parts of purified mercury, five parts of diluted nitrous acid, 15 parts of diſtilled water, and a ſufficient quantity of water of carbonate of ammonia. Diſſolve the mercury in the acid; add gradually the diſtilled water, then pour in as much water of carbonate of ammonia as may be ſufficient for precipitating the whole of the oxyd of mercury, which is to be afterwards waſhed with pure water, and dried.

Hydrargyri Pulvis cinereus, Dubl. grey powder of mercury, is formed by diſſolving 2 oz. of mercury in two fluid-ounces of diluted nitrous acid, in a ſlow heat, and diluting the ſolution with eight fluid-ounces of cold water; then dropping into it $1\frac{1}{2}$ oz. of the water of carbonate of ammonia, or as much as may be ſufficient for precipitating the whole of the metal, which is to be waſhed with boiling diſtilled water, until the fluid, poured off, yields no ſediment, when water of ſulphuret of ammonia is dropped into it: laſtly, let the precipitate be dried. The conſtituents of the grey oxyd of mercury are ſuppoſed to be 96 parts of mercury, and 4 of oxygen, in 100 parts.

The grey oxyd of mercury, when well prepared, may be uſed as a ſubſtitute for the oxyd prepared by trituration; and as it is more likely to be always of an uniform ſtrength, it may of courſe be more depended on than thoſe preparations. It has been objected to for forming ointment, in order to ſerve the purpoſes of mercurial frictions (ſee UNGUENTUM *Oxydi hydrargyri cinerei*); but the objection may have been owing to the uſe of that form of preparation which contains the triple ſalt. It has been uſed with advantage for fumigation, both locally applied towards the healing of venereal ulcers, and, generally, to bring the habit under the influence of mercury, when it could not be introduced by the ordinary mode. The doſe of this oxyd is from gr. i. to grs. iii. given in the form of pill twice a day.

Hydrargyri, Sulphuretum nigrum, olim, *Æthiops mineralis*, Edinb. Dubl. black ſulphuret of mercury, formerly æthiops mineral. This is prepared by rubbing together equal weights of purified mercury and ſublimed ſulphur in a glaſs mortar with a glaſs peſtle, until the globules of mercury altogether diſappear. It may alſo be made with double the quantity of mercury.

This mercurial preparation is alterative and anthelmintic; it is chiefly employed againſt ſcrophulous ſwellings, and in cutaneous affections; and has been found uſeful as an antidote to aſcarides. It muſt be long uſed to produce any ſenſible effects. The doſe is from grs. v. to f.ʒſs., given twice or three times a day. See ÆTHIOPS *Mineral*.

Hydrargyri ſulphuretum rubrum, red ſulphuret of mercury, Hydrargyrus ſulphuratus ruber, P. L. 1787, Cinnabaris factitia, P. L. 1745, is prepared by melting 8 oz. of ſublimed ſulphur over the fire, and mixing in 40 oz. by weight, of purified mercury; and as ſoon as the maſs begins to ſwell, removing the veſſel from the fire, and covering it with conſiderable force, to prevent inflammation; then rubbing the maſs into powder and ſubliming.

Hydrargyri, Sulphuretum rubrum, Dubl. red ſulphuret of mercury, is prepared as in the laſt proceſs. Red ſulphuret of mercury is alterative and deobſtruent. It was formerly much uſed in cutaneous diſeaſes, gouty and rheumatic affections, and in caſes of worms, but it is now ſcarcely ever employed. It has been recommended for fumigations in ſyphilis; but on account of the ſulphurous vapours it is leſs fit for this purpoſe than the grey oxyd. The doſe for internal uſe is from grs. x. to ʒſs. made into an electuary or bolus.

Hydrargyri Subſulphas flavus, olim, *Turpethum minerale*, Edinb. yellow ſubſulphate of mercury, formerly, Turbith mineral, Hydrargyrus vitriolatus, P. L. 1787; alſo Mercurius emeticus flavus. For preparing it, take of purified mercury 4 oz.; ſulphuric acid 6 oz.; put them into a glaſs cucurbit, placed in a ſand-bath, and boil them to dryneſs; pulverize the white maſs which is left at the bottom of the veſſel, and throw it into boiling water; it will be immediately converted into a yellow powder, which is to be waſhed with frequent affuſions of warm water.

Hydrargyri Oxydum ſulphuricum, Dubl. ſulphuric oxyd of mercury, is prepared by diſſolving in a glaſs veſſel 1lb. of purified mercury, in $1\frac{1}{2}$lb. of ſulphuric acid, with a ſufficient degree of heat, and gradually raiſing the fire until the maſs be completely dried. This, by the affuſion of a large quantity of hot water, will immediately become yellow and fall into powder, which is to be well triturated with the water in an earthenware mortar. After pouring off the ſupernatant fluid, waſh the powder with repeated affuſions of hot diſtilled water, as long as any precipitate is produced in the decanted liquor on the addition of a few drops of water of ſubcarbonate of kali; and, laſtly, dry it.

This preparation is emetic, diſcutient, alterative, and errhine; but as its operation is violent, it is ſeldom adminiſtered as an internal remedy. As an errhine, it has been uſeful in chronic ophthalmia, and diſeaſes of the head; but in this caſe its acrimony ſhould be ſheathed by ſome bland powder, as ſtarch, or liquorice-root powder, in the proportion of grs. v. to gr. i. of the ſubſulphat. In doſes of gr. v. it operates as a very powerful emetic.

MERCURY, *Coralline*. See ARCANUM *Corallinum*.

MERCURY, *Fulminating*. This curious compound was diſcovered by Mr. Howard, who has given us the following proceſs for preparing it. Diſſolve 100 grains of mercury in $1\frac{1}{2}$ ounce, by meaſure, of nitric acid, of the ſpecific gravity of 1.3, with the aſſiſtance of heat. When this ſolution is cold, pour it upon two ounces, by meaſure, of alcohol: let this mixture be expoſed to heat till an efferveſcence takes place, when the heat muſt be withdrawn. The efferveſcence continues with violence for ſome time, accompanied by the evolution of a denſe white vapour, which Mr. Howard conceived to be the etherized nitrous gas combined with oxyd of mercury. During this proceſs a white powder gradually ſubſides, which muſt be well waſhed, filtered, and dried on a ſand-bath heated by ſteam, as a temperature a little higher would cauſe its exploſion. The powder thus obtained is rather cryſtalline in its appearance. When it is heated to 368°, it explodes with great violence, producing a vivid flaſh of light, with but little heat. The ſame exploſion takes place by the blow of a hammer, by an electric ſpark, and by flint and ſteel. The ſurface of the body on which it is exploded becomes always covered with a white film, which is the reduced mercury. This indicates that the oxygen of the oxyd has had ſome ſhare in producing the effect. The exploſion by means of a blow is ſo violent, as frequently to indent

indent the face of the hammer and the anvil. When concentrated fulphuric acid is added to fulminating mercury, it inftantly explodes. The dilute acid decompofes it without explofion. A gafeous fubftance is given out, which confifts of carbonic acid mixed with an inflammable gas, which burns with a greenifh flame. A white powder is at the fame time precipitated, which is the oxalat of mercury mixed with a little running mercury. The compofition of fulminating mercury is, therefore, found to be oxalat of mercury combined with the etherized nitrous gas. This fubftance has been fince examined by other chemifts. Fourcroy is of opinion that it may be varied in its properties by varying the procefs. When heat is continued during the whole time of the effervefcence, a fubftance is produced of a greenifh colour, which detonates with lefs force, and emits a blue flame when laid on hot coals. In this cafe, Fourcroy fuppofes it to contain ammonia, and more of the vegetable matter of the alcohol. We have before noticed that the oxalat of mercury has the property of exploding with the blow of a hammer. Hence it would appear, that any fubftance holding oxygen with flight affinity, and at the fame time combined with inflammable matter, particularly fuch as contains hydrogen, may conftitute an explofive compound. It is faid by Brugnatelli, that a nitrat of filver with excefs of acid being heated with alcohol, affords a fulminating fubftance more violent in its effects than the fubftance in queftion. This no doubt arifes from the oxygen of the filver giving up lefs of its fpecific caloric when it combines with that fubftance, and of courfe has more to give up when it combines with the inflammable matter derived from the alcohol. Notwithftanding the myftery fo much talked of in the firing of gunpowder, it might no doubt be proved that the light and heat given out when the explofion takes place, is the difference between what would be afforded by the combuftion of nitrogen, and the carbon and fulphur of the gunpowder. See Nitric *Acid*.

M. Bayen was the firft chemift who obferved the fulminating property of the oxyds of mercury when heated with fulphur; and hence mixtures of this kind have been denominated "Bayen's fulminating mercury." The moft powerful of thefe mixtures is thus prepared; to a folution of nitrat of mercury add lime-water, as long as any precipitate falls down; decant the clear liquor, and wafh the pulverulent oxyd with repeated portions of water, after which dry it on a water bath, and then grind it carefully in a mortar, with $\frac{1}{6}$th of its weight of flower of fulphur. This powder, when laid on a hot iron, explodes with confiderable force, undoubtedly in confequence of the fudden oxydation of the mercury, and the rapid combuftion of part of the fulphur; for if it is performed in a clofe veffel, to prevent the diffipation of the powder, the refult of its decompofition will be a reddifh violet-coloured fulphuret, fimilar to that procured in the ufual manner. Aikin's Dict.

Mercury, *Incalefcent*. See Incalescent.

Mercury, *Ointment of*. See Unguent.

Mercury, *Pills of*. See Pills.

Mercury, *Plafter of*. See Emplastrum and Plaster.

Mercury, or *Mercury of Bodies*, has been ufed by alchemifts to denote the third of the principles or elements of natural bodies, called alfo fpirit.

In this fenfe, mercury is defined the moft fubtile, light, volatile, penetrating, and active part of all bodies. See Spirit.

Mercury *of Life*, *Mercurius vitæ*, may, according to Mr. Boyle, be moderated in its evacuating quality, by continually ftirring it in a flat glazed earthen veffel, over a fire, till it emits no fumes, and turns of a grey colour; and he thinks this is the *mercurius vitæ furgans* fo often mentioned by Riverius. Boyle, Works abr. vol. i. p. 74.

Mr. Godfrey obferves, that what is called *mercurius vitæ*, prepared of fublimate mercury and antimony, has no mercury in it, but is the reguline part of the antimony, with the acid of the fublimate; and what remains is the mercury formed into cinnabar by the fulphur of the antimony. See Algarot.

Mercury *of Metals*, or of the *philofophers*, is a pure fluid fubftance in form of common running mercury, faid to be found in all mercury, and capable of being extracted from the fame.

The notion of mercury of metals is founded on the common fyftem of the alchemifts, that mercury or quickfilver is the bafis or matter of all metals; and that metals are only mercury fixed by a certain fulphur.

Mr. Boyle affures us, he had a way of drawing a true running mercury, or quickfilver, from antimony.

Mercury alfo ferves as a title for books, and papers of news; fo called from the heathen deity Mercury, fuppofed the meffenger of the gods.

In the like fenfe, Mercury is always figuratively applied to perfons who make it their bufinefs to collect news, or to run about and diftribute it.

Mercury, in *Heraldry*, denotes the purple colour in the coats of fovereign princes. See Colour.

Mercury, in *Mythology*, the fon of Jupiter and Maia. He was the god of merchandize, and therefore was fometimes painted with a wand in his left hand, and a bag of money in his right. He was alfo the god of eloquence, and the meffenger of the gods; and, as fuch, concerned in all treaties of peace and alliance. He is pictured, therefore, with a herald's ftaff in his hand, entwined with two fnakes; wings on his feet, to fhew his fpeed; and a broad-brimmed beaver with wings. He had a general power delegated to him by Jupiter, of conducting the fouls of men to their proper place, after their parting from the body; and re-conducting them to our world again, when there was any particular occafion for it. He was, moreover, the god of all gainful arts; whence the proverb κοινὸς ἑρμῆς, i. e. *commune lucrum*; efpecially of things found by chance, the inventor of the lyre, and of the exercife of wreftling. He was the patron of thieves, having himfelf been expert that way; and the guide of travellers, for which reafon he had ftatues four-fquare fet up to him in crofs-roads. (See Terminus.) There are feveral marks whereby Mercury may be known; among which we may reckon the lightnefs and agility of his perfon as the chief; but the moft remarkable of his diftinguifhing attributes are his petafus, or winged cap; the talaria, or wings to his feet; and his wand, with two ferpents about it, which they call his caduceus. Sometimes he is alfo reprefented with the chlamys, faftened over his fhoulders on his breaft, and floating behind him in the air. He is likewife diftinguifhed by his fword, with which he killed Argus, called Harpé. As the form of Mercury feems to be all intended for lightnefs and difpatch, the ancients might borrow this idea of him from his planetary character: thus Lucan, Pharfal. i. v. 663, in fpeaking of Mercury as the guiding intelligence of a planet, marks the fwiftnefs of its motion.

It has been faid, and not without reafon, that the Mercury of the Latins was the fame deity with the Hermes of the Greeks, the Theutat of the Gauls, and the Thot or Thaut of the Egyptians, from whom fome have thought they were derived. His name Hermes fignified Interpreter, or, or, according to Proclus, Meſſenger, or, if we trace it to a Celtic original, it was the ſame with *arines*, which ſignifies divination, a character which belonged by way of eminence to Mercury, who was diſtinguiſhed by his knowledge and practice of this art. The Latin appellation was derived, according to Feſtus, from a term denoting merchants, or rather merchandize, *i. e. Mercurius a Mercibus;* and among the Celts he obtained the name of Merk-ur, on account of his introduction of traffic among them. Lactantius, the grammarian, reckons four of this name, and according to Cicero there were five. Banier allows of none but the ancient Mercury, the Thot, Thaut, or Taautus of the Egyptians, and the Mercury, who, according to Heſiod, was the ſon of Jupiter and Maia. To this deity temples were built, and altars erected. There is no perſonage in profane antiquity more famous than the Egyptian Mercury. Being the ſoul of Oſiris's counſel, he was employed as his agent in the moſt important offices; and during his abſence in India, he aſſiſted Iſis, the queen, with his advice, and exerted himſelf with great aſſiduity and zeal in cauſing arts and commerce to flouriſh through the whole country of Egypt. As he was a proficient in various ſciences, he communicated his knowledge to the Egyptians, and eſtabliſhed among them a variety of inſtitutions, which contributed to their reputation and proſperity. Such is the account which is given of him by Herodotus and Diodorus Siculus. The ſecond Mercury, or the ſon of Jupiter and Maia, became famous among the Titan princes, and took poſſeſſion of Italy, Gaul, Spain, and Mauritania in Africa. This prince is ſaid to have travelled more than once into Egypt, in order to acquaint himſelf with the arts and ſciences, the manners and cuſtoms, and particularly the theology and magic of that country. He was thus enabled, upon his return, to inſtruct his own ſubjects, and to acquire that high reputation for which he was diſtinguiſhed, by exhibiting thoſe qualities and performing thoſe ſervices, which we have above recited. After various conteſts with the other ſons of Jupiter, by whom he was repeatedly vanquiſhed, he is ſaid to have retired into Egypt, where he died; though others ſay he ended his days in Spain, where his tomb was to be ſeen. Such, ſays Banier, is the hiſtory of Mercury, the Titan prince, which has been much diſguiſed by the Greeks, and blended with ſeveral fables. Mercury was worſhipped by the Gauls, as Cæſar informs us, but, as we learn from Kircher, (Œd. Ægypt.) in Egypt, where the prieſts conſecrated to him the ſtork, the animal moſt renowned among them next to the ox. It was chiefly in the month of May that his feſtival was celebrated, and the moſt ſolemn parts of his worſhip were performed.

The learned Bochart (Phaleg. l. i. c. 2.) traces the hiſtory of Mercury to that of Canaan. Both, he ſays, were the ſons of Jupiter, or Ammon, who was the ſame with Ham; one taking his name from *Mercatura*, merchandize, and Canaan, he ſays, had in Hebrew the ſame ſignification. As Canaan was the ſervant of his brethren, Mercury was the meſſenger of the gods. This deity had the charge of the highways, becauſe the Phœnicians or Canaanites of the race of Canaan were great travellers, and ſettled colonies whereever they migrated. The wings of this god are the ſails of the Phœnician veſſels. He was the god of eloquence, and the inventor of letters, becauſe the Phœnicians brought the uſe of them into the Weſt. Others repreſent Mercury as the ſame with Moſes, and compare the miraculous rod of that legiſlator to the caduceus of this god. Such is the opinion of Huetius.

This pagan divinity had two very diſtinct names and characters; the Egyptian, known by the title of Hermes, a grave and venerable perſonage, who received divine honours on account of his uſeful and extenſive talents for every thing that was conducive to the good of ſociety: the Mercury of the Greeks, on the contrary, was a profligate character; the god of thieves, the intriguing meſſenger of Jupiter, and uſeful to him in all his amours. But to both theſe divinities is aſcribed the invention of muſic and the lyre.

Among the various opinions of the ſeveral ancient writers who have mentioned this circumſtance, and confined the invention to the Egyptian Mercury, that of Apollodorus is the moſt intelligible and probable. "The Nile," ſays this writer, "after having overflowed the whole country of Egypt, when it returned within its natural bounds, left on the ſhore a great number of dead animals of various kinds, and among the reſt, a tortoiſe, the fleſh of which being dried and waſted by the ſun, nothing was left within the ſhell, but nerves and cartilages, and theſe being braced and contracted by deſiccation, were rendered ſonorous; Mercury, in walking along the banks of the Nile, happening to ſtrike his foot againſt the ſhell of this tortoiſe, was ſo pleaſed with the ſound it produced, that it ſuggeſted to him the firſt idea of a lyre, which he afterwards conſtructed in the form of a tortoiſe, and ſtrung it with the dried ſinews of dead animals."

Of the Grecian Mercury, Horace, Ode x. lib. 1. gives us the beſt part of his character:

"Thou god of wit, from Atlas ſprung,
Who by perſuaſive power of tongue,
And graceful exerciſe, refin'd
The ſavage race of human kind,
Hail! winged meſſenger of Jove,
And all th' immortal powers above.
Sweet parent of the bending lyre,
Thy praiſe ſhall all its ſounds inſpire.
Artful and cunning to conceal
Whate'er in ſportive theft you ſteal,
When from the god who gilds the pole,
E'en yet a boy, his herds you ſtole:
With angry voice the threat'ning pow'r
Bad thee thy fraudful prey reſtore,
But of his quiver too beguil'd,
Pleas'd with the theft, Apollo ſmil'd.
You were the wealthy Priam's guide,
When ſafe from Agamemnon's pride,
Through hoſtile camps, which round him ſpread
Their watchful fires, his way he ſped.
Unſpotted ſpirits you conſign
To bliſsful ſeats and joys divine,
And, powerful with thy golden wand,
The light unbodied crowd command;
Thus grateful does thy office prove
To gods below, and gods above." Francis.

This ode contains the ſubſtance of a very long hymn to Mercury, attributed to Homer. See HERMES.

MERCURY *Bay*, in *Geography*, a bay on the N.E. coaſt of the northernmoſt of New Zealand, ſo called by lieutenant Cook, who anchored here in 1769, examined the adjoining country, and in November of the ſame year obſerved the tranſit of Mercury over the ſun, from which planet it derived its name. Southward and northward of this bay, there are ſeveral iſlands, and a ſmall iſland or rock in the middle of the entrance; within which iſland the depth of water no where exceeds nine fathoms. The beſt anchoring is in a ſandy bay, which lies juſt within the ſouth head, in five and four fathoms. This place is very convenient both for wooding and watering, and in the river there is an immenſe quantity of oyſters

oysters and other shell-fish, whence it was called by Cook the "Oyster river." But for a ship that wants to stay here any time, the best and safest place is in the river at the head of the bay, which, from the number of mangrove trees about it, was called "Mangrove river." To sail into this river, the south shore must be kept all the way on board. The country on the east side of the river and bay is very barren: its only produce being fern, and a few other plants that will grow in a poor soil. The land on the N.W. side is covered with wood, and the soil being much more fertile, would, with proper cultivation, produce all the necessaries of life; it is not, however, so fertile as the land observed by our navigators to the southward; nor do the inhabitants, though numerous, make so good an appearance: they have no plantations; their canoes are mean, and without ornament; they sleep in the open air; and say, that Teratu, whose sovereignty they do not acknowledge, if he were to come among them, would kill them. This favoured an opinion of their being outlaws; though they had "Heppahs," or strong holds, to which they retired in time of imminent danger. On the shore, in several parts of the bay, were found great quantities of iron sand, which is brought down by every little rivulet of fresh water, that finds its way from the country; a circumstance which demonstrates that there is ore of that metal not far inland; nevertheless none of the inhabitants of this place, or any other part of the coast, observed by Cook and his companions, knew the use of iron, or set the least value upon it: all of them preferring the most worthless trifle, not only to a nail, but to any tool of that metal. Our navigators, before they left the bay, cut upon one of the trees near the watering place, the ship's name and that of the commander, with the date of the year, and month when they were there; and after displaying the English colours, took a formal possession of it in the name of his Britannic majesty king George III. S. lat. 36°47′. W. long. 184° 4′. Hawkesworth's Voyages, vol. ii.

MERCURY *Point*, a cape on the E. coast of New Zealand, forming the N.E. point of Mercury bay.

MERCURY *Isles*, a cluster of small islands in the South Pacific ocean, near the E. coast of New Zealand, situated in a line, a little N.E. of Mercury Point.

MERCY, in *Ethics*, has the same general nature and sources as *compassion*, which see; and seems to differ from it only in this, that the object of it has forfeited his title to happiness, or the removal of misery, by some demerit, particularly against ourselves. Here, therefore, resentment on account of an injury done to ourselves, or what is called a just indignation against vice in general, interferes, and checks the otherwise natural course of our compassion, so as, in the unmerciful, entirely to put a stop to it. But in the merciful, the sources of compassion prevail over those of resentment and indignation; whence it appears, that the compassion required in acts of mercy is greater than in common acts of mere compassion; agreeably to which it is observable, that mercy is held in higher esteem than mere compassion. The mercy of God is that attribute of the divine nature, or that modification of benevolence, which respects the misery of mankind in connection with their offences and demerit; and the exercise of it makes provision for their relief by affording them the means of recovery, by repentance and reformation, so that they may become fit objects of pardon and favour.

MERCY, in *Law*. See MISERICORDIA.

MERCY, *Order of our Lady of*, was instituted, for the redemption of captives, as several writers affirm, by James I. king of Arragon, in 1218; but others, on better authority, attribute the institution of the order to Peter Nolasque, a native of Mar des Saintes Puelles, a town in the diocese of St. Papoule, one league distant from Castelnaudary. The badge worn by the knights at their breast was a small shield per fess gules and or; in chief, a cross pattée argent; in base four pallets gules, for Arragon: the shield crowned with a ducal coronet.

MERCY, *Religious Order of*, is said to have been instituted and liberally endowed, for ladies, in 1261, by Mary du Secours, a woman of quality born at Barcelona: the ladies of this order wore at their breast a small shield of the arms of the order, exactly similar to that worn by the knights.

MERCY-*Seat*, in *Scripture History*. See ARK *of the Covenant*.

MERDDIN, in *Biography*, the son of Mervyn, a celebrated Welsh poet, who flourished about A. D. 560. He ranked with Merddin Emyls, and Taliessin, as the three principal Christian bards of Britain. Merddin is said to have slain his nephew in battle, on which account he secluded himself from society in a wood, whence he is called Merddin the Wild. Owen's Camb. Biog.

MERDESENGI. See MARDAC.

MERDIN, or MARDIN, in *Geography*, a fortified town of Asiatic Turkey, in the province of Diarbekir. It is situated at the top of a very lofty and rugged mountain, surrounded by a strong and lofty wall of hewn stone, and guarded by a strong fort on the summit of the mountain, furnished with a few cannon. This town is of a considerable size, and very populous. It is the see of a bishop, and the greater part of its inhabitants consists of Armenians, who are very industrious, and carry on several manufactures. They are hospitable and well disposed, enjoy a pure air, and in general appear ruddy and healthy. Many of the women are beautiful. Provisions, and particularly vegetables, are plentiful, good, and cheap; and they have also most kinds of fruits, of excellent quality, the climate being very hot in the vallies, and temperate on the mountains. It is the residence of a pacha, in whose train are 200 spahis and 500 janizaries. This town, which seems to have been called "Zibin" by Rauwolf, was taken and sacked by Timur Bec, but the fortress was invincible; 50 miles S. of Diarbekir. N. lat. 37° 19′. E. long. 40°.

MERDIVORÆ, from *merda*, *dung*, and *voro*, *I devour*, the *dung-eaters*, in *Natural History*, the name given by authors to several flies, which feed on excrements of different animals. Of these there are three kinds very common among us; 1. The coprophagos, which is of a dun colour, with a reddish head, and a white streak along the middle of it: 2. The red dung-fly, which has silvery wings, a red body, and black shoulders: and, 3. The green one, which is of a very glittering hue, and has silvery wings.

MERDOO, in *Geography*, a town on the N. coast of the island of Sumatra. N. lat. 5°. E. long. 96° 20′.

MERDRIGNAC, a town of France, in the department of the Northern Coasts, and chief place of a canton, in the district of Loudéac; 13 miles E. of Loudéac. The place contains 2134, and the canton 10,044 inhabitants, on a territory of 302½ kiliometres, in nine communes.

MERE, a town of Norway, in the government of Drontheim; 68 miles N. of Drontheim.

MERE, a small market-town and parish, situated in the hundred of Mere, and county of Wilts, England. The parish is of an angular shape, and is bounded on two sides by the counties of Somerset and Dorset. Hence it is supposed to have derived its name. *Mere*, in the Saxon language, is often used to denote a boundary or land mark. The appearance of the town is that of a straggling village, the houses

houses being ill arranged and very indifferently built. In the middle of it stands a small cross or market-house, where a weekly market is held on Thursdays, and two fairs annually. According to the parliamentary returns of 1801, it contained 181 houses, and 381 inhabitants. A manufactory of bed-ticking and dowlas is carried on here chiefly by the women. The church is an extensive edifice, ornamented at one end by a handsome tower. The living is vicarial, and in the gift of the dean of Salisbury. In the parsonage house was born Francis Potter, one of the most singular mechanical geniuses of his age.

On an eminence still called Castle-hill, immediately adjoining the town, formerly stood a castle, but few traces of its walls can now be discovered. Some encampments appear in this neighbourhood, one of which, called by Leland "White-shole-hill," is surrounded by a double trench, and was probably occupied by the Danish army, previous to some engagement with the celebrated Alfred.

About two miles N.W. of Mere is the parish of Stourton, in which is a noble seat, named Stourhead, the seat of sir R. C. Hoare, bart. This gentleman has distinguished himself in the literary annals of the present age, by the publication of some interesting and handsome works on the topography and antiquities of Great Britain. One of these, entitled "The History of Ancient Wiltshire," contains much new and curious information respecting the characteristics of encampments, barrows, stonehenge, &c. and a particular account of some singular excavations, called Penn-pitts, in this neighbourhood. Stourhead is justly noted among the handsome seats of this county; and though the house has no prominent architectural beauties, yet it is stored with choice pictures, with drawings, and an extensive and well selected library. The pleasure grounds, woods, and water, display many picturesque and sylvan beauties, and the whole demesne is highly impressive and interesting. See Britton's Beauties of Wiltshire.

MERECZ, a town of Lithuania, in the palatinate of Troki, at the conflux of the Merecz and the Niemen; 28 miles N. of Grodno.

MEREDITH, Cape, a cape among the Falkland islands, in the South Atlantic ocean, between port Stephen's and cape Orford.

Meredith, a township of America, in Strafford county, New Hampshire, on the S.W. side of lake Winipiscogee; 15 miles N. of Gelmantown, and nine S.E. of Plymouth; incorporated in 1768, and first called New Salem.—Also, a post-town in Delaware county, New York; 25 miles S. of Cooperstown.

MEREEGA, Hammam, *i. e.* the baths of Mereega, formerly the "Aquæ Calidæ Coloniæ," a town of Algiers, in the province of Tlemsan or Tremecen, situated half way betwixt the shelliff and the sea, eight miles E.N.E. of Maliana, and celebrated for its hot baths. The largest and the most frequented of them is a bason 12 feet square, and four deep: and the water, which bubbles up in a degree of heat scarcely supportable, after it has filled this cistern, passes on to a much smaller one used by the Jews, who are not permitted to bathe in company, or in the same place with the Mahometans. These baths were formerly covered, and had corridores surrounding the basons; but they now lie exposed to the weather, and are half filled with stones and rubbish. Neverthelefs they are resorted to by a great concourse of people in the spring, which is the season of these waters; accounted very efficacious for curing the jaundice, rheumatic pains, and some of the most inveterate distempers. Higher up the hill is another bath, which being of too intense a heat for bathing, has its water conducted through a long pipe into another chamber, where it is used in "Duccian," an operation similar in its nature and effect with pumping. Betwixt this and the lower bath are the ruins of an old Roman town equal to that of "Herba; and at a little distance from it are tombs and coffins of stone, of an unusual size; 24 miles S.E. of Shershell. Shaw's Travels.

MERENDERA, in *Botany*, a name given by the Spaniards to this plant and some that resemble it, and which may perhaps be tolerated, like a few others of barbarous origin, as being sufficiently harmonious. Ramond Bullet. Philomat. n. 47. 178. t. 12. f. 2. Redout. Liliac. v. 1. 25.—Class and order, *Hexandria Trigynia*. Nat. Ord. *Coronariæ*, Linn. *Junci*, Juss.

Cal. Sheath of one leaf. *Cor.* of six petals, funnel-shaped, equal; claws erect, long and linear; borders elliptic-lanceolate, spreading. *Stam.* Filaments six, thread-shaped, equal, inserted into the claws of the petals, shorter than the limb, permanent; anthers terminal, erect, awl-shaped. *Pist.* Germen three-lobed, superior, somewhat stalked, oblong, acute; styles thread-shaped, the length of the stamens; stigmas simple. *Peric.* Capsule stalked, oblong, three-lobed, acute, of three valves and three cells, opening at their inner edge. *Seeds* several in each cell, obovate, stalked, ranged along the margins of each valve.

Ess. Ch. Sheath of one valve. Petals six, with long claws. Anthers vertical. Capsule of three cells, opening at their inner edge. Seeds several.

1. M. *Bulbocodium*. Pyrenean Merendera. Redout. Liliac. t. 25. (Bulbocodium vernum; Desfort. Atlant. v. 1. 284, excluding the synonyms, according to Redouté, but the description does not entirely agree. Colchicum montanum minus, versicolore flore; Clus. Hist. v. 1. 201. Ger. em. 160.)—Found in the grassy pastures of the highest of the Pyrenean mountains, flowering at the commencement of autumn, and ripening seed in the following spring. *Root* an ovate bulb. *Stem* none. *Leaves* three or four, produced after the flower is past, radical, spreading, linear, acute, channelled, smooth, a span long. *Flower* solitary, radical, the size of a small Crocus, with purplish rose-coloured petals, white at their base, and yellow anthers. *Capsule* small, brown, elevated on a stalk two inches high.—We have copied from Redouté the quotation of Ramond. This plant might perhaps, without violence to nature, be referred to *Colchicum*.

MERETRIX, among the Romans. The meretrices were the better sort of courtezans, and differed much from the *prostibulæ*, or common prostitutes, who had bills or inscriptions, *tituli*, over their doors, and were ready at all times to entertain their customers, whereas the meretrices entertained none but at night.

The meretrices were distinguished from the matrons by their dress, being obliged to wear the *toga* and short tunics, like those of the men; whereas the matrons wore the *stola*, which was a garment that reached down to their feet, as did likewise their *palla*, or outer robe.

MÉRÉVILLE, in *Geography*, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Corbeil; 10 miles from Estampes. The place contains 1307, and the canton 8012 inhabitants, on a territory of 240 kilometres, in 20 communes.

MERG, a town of Africa; 30 miles N. of Fez.

MERGANSER, in *Ornithology*, the name of a large water-fowl, called in English the *goosander*, and by some authors the *harle*.

This is the Mergus merganser in the Linnæan system: the bill of the male of this species is about three inches long,

long, narrow, and finely ferrated: the colour of the bill as well as of the irides is red; the head is large, and the feathers on the hind part long and loofe; the colour black, finely gloffed with green; the upper part of the neck the fame; the lower part and under fide of the body of a fine pale yellow; the upper part of the back and inner fcapulars are black; the lower part of the back and tail are afh-coloured; the tail confifts of eighteen feathers; the greater quill-feathers are black, the leffer white, fome of which are edged with black; the coverts at the fetting on of the wings are black; the reft white; and the legs of a deep orange colour. Pennant. See MERGUS.

MERGEN, a word ufed by fome of the chemical writers to exprefs coral.

MERGENTHEIM, in *Geography*, a town of Germany, on the S. fide of the Tauber; the refidence of the grand mafter of the Teutonic order, and feat of the regency; 25 miles S.S.W. of Wurzburg. N. lat. 49° 21′. E. long. 9° 27′.

MERGER, in *Law*, is where a leffer eftate in lands, &c. is drowned in the greater; as, if the fee comes to tenant for years or life, the particular eftates are merged in the fee: but an eftate tail cannot be merged in an eftate fee; for no eftate in tail can be extinct, by the acceffion of a greater eftate to it. If a leffor, who had the fee, marries with the leffee for years, this is no merger, becaufe he hath the inheritance in his own, and the leafe in right of his wife. And where a man hath a term in his own right, and the inheritance defcends to his wife, fo that he hath a freehold in her right, the term is not merged or drowned.

MERGIAN, in *Geography*, a town of Perfia, in the province of Segeftan; 32 miles S.S.W. of Kin.

MERGUEN HOTUN, a town of Chinefe Tartary; 670 miles N.N.E. of Peking. N. lat. 49° 12′. E. long. 142° 20′.

MERGUI, a fea-port town of the kingdom of Siam, fituated S. of Tavoy, on an ifland near the E. coaft, with a harbour that is accounted one of the beft in India. The fea near the coaft being full of iflands, is denominated by captain Forreft the Mergui Archipelago. N. lat. 12° 6′. E. long. 98° 23′.

MERGUS, in *Ornithology*, a genus of birds of the order Anferes. The trivial name of this genus is *Merganfer*: the bill is toothed, flender, cylindrical, hooked at the point; noftrils fmall, oval, in the middle of the bill; feet four-toed, the outer toe longeft. There are ten fpecies, of which five are common to our country; the others are natives of Europe and America. The birds of this genus live on fifh, and are very deftructive in ponds.

Species.

CUCULLATUS, Crefted Merganfer. Creft globular, white on each fide; body above brown, beneath white. It inhabits North America; and is 17 inches long; it builds near lakes, forming its neft of grafs, and down plucked from its own breaft; lays from four to fix eggs. The bill and legs are black; irids golden; creft larger than the head, edged with black. The female is brown; creft lefs, ferruginous.

* MERGANSER, Goofander. Subcrefted; white head; neck, upper part of the breaft, and wings gloffy-black; tail cinereous. It weighs about four pounds when full grown; its length is two feet four inches. It is found in Europe, Afia, and America. Sometimes the goofander vifits our rivers and lakes in fevere winters, but retires to the more northern latitudes to breed. It has been known to build on trees, like the cormorant, but more frequently among rocks or ftones, and lays 14 eggs, which, with the bird itfelf, are eagerly devoured by the weazel. It fwims with its head above the water; dives deep; remains a long time below, and rifes at a confiderable diftance. Its flefh is rancid, though fometimes eaten. In queft of fifh, it dives with great celerity, and holds its flippery prey with great fecurity by means of its toothed bill, fo admirably adapted to the purpofe. Bill, legs, and irids red; greater quill-feathers black, leffer white.

* CASTOR, Dun-diver. Crefted, cinereous; head and upper part of the neck bay; chin, middle quill-feathers, and belly white. It weighs about two pounds and a half, meafures twenty-five inches in length. Inhabits the fame countries with the preceding. It has been regarded by fome naturalifts as the female of another fpecies, but the labyrinth, or enlargement at the bottom of the wind-pipe, feems to others to prove it to be a male, and confequently a diftinct fpecies. Bill and irids red; belly fometimes flefh-colour

* SERRATOR, Red-breafted Merganfer. Creft pendent; breaft variegated with reddifh; collar white; tail-feathers brown, varied with cinereous. It inhabits the northern parts of Europe, Afia, and America; and is 21 inches long. The bill beneath and legs are red; feathers of the fides of the breaft large, white, edged with black, covering the fore-part of the folded wings. In the *male* the hind-head is crefted; head and upper part of the neck green. The *female* is fcarcely crefted at all; the head and beginning of the neck rufous. There are two other varieties diftinguifhed by differences of colouring marks; the *fecond* above is black, beneath white; greater quill-feathers black; tail brown; variety of the male: the *third* is above black, beneath white; neck bay; wings with a tranfverfe white ftripe; greater quill-feathers and tail black; variety of the female.

IMPERIALIS, Imperial Goofander. Varied with black, brown, and grey; head fmooth; firft quill-feathers black; it has no wing-fpot; bill and legs reddifh-white. It inhabits Sardinia; is the fize of a goofe; and the tongue fringed.

* ALBELLUS, Smew or White Nun. Creft pendent; hind-head black; body white; back and temples black; wings variegated. Inhabits Europe and America; breeds in the Arctic regions, and is driven to the fouth only by fevere weather. Bill and legs black; wing-fpot white; oval fpot from the bill furrounding the eyes, back, and two arched lines on each fide near the beginning of the wings, black. Female, head fmooth, grey; band acrofs the eyes black, and under the eyes a white fpot; body above blackifh-brown, beneath white; upper part of the head bay; chin white.

* MINUTUS, Minute Merganfer. Brown-afh, beneath and chin white; head and upper part of the neck ferruginous; wing-fpot white before and behind. There is a variety having a fmooth head; black back; belly white; bill and legs blood-red; firft quill-feathers black; tail cinereous.

FURCIFER, Fork-tailed Merganfer. Black; head fmooth; hind-head, neck, vent, belly, and lateral tail-feathers white; front and cheeks pale brown; the tail is forked. Bill black; dirty-red at the fides; from the ears on each fide, through the fides of the neck to the breaft, there is a black band.

FUSCUS, Brown Merganfer. Crefted; brown, beneath white; chin and breaft fpotted with black; wings black with a white band. It is found in Hudfon's bay, and is 17 inches long. Hind-head crefted; behind the eyes a white band

band extending to the nape; lower part of the creſt black; breaſt blueiſh waved with whitiſh; legs yellowiſh.

Cæruleus, Blue Merganſer. Creſted; blue; crown and tail black; chin, belly, and ſpot on the wings white. It inhabits Hudſon's bay, and is 14 inches long. The bill of this ſpecies is long and black; legs are blue. We ſhall now conclude this article with ſome general obſervations on the whole genus.

Theſe birds, with few exceptions, are of a middle ſize, between that of a gooſe and of a duck. The edges of both mandibles are ſerrated, the tongue is thick, ſet with ſmall briſtles pointing backward; an happy contrivance for holding the ſlippery fiſhes which form their prey, and conducting it into the bird's throat. They ſwallow with an undiſtinguiſhable voracity, fiſhes, that are by far too large to enter entire into the ſtomach; and hence, while the one end is digeſting in the œſophagus, the other often remains in the throat.

The head and back of the merganſer are black, beautified with a gloſs of green. The lower parts of the body are white, the breaſt tending to a pale yellow. The tail is grey, the eyes, feet, and part of the bill, are red. As this bird is obliged to ſearch for its food by diving, it is capable of remaining a long time under water; and for this purpoſe, is furniſhed with a quantity of air, lodged in a cavity of its body, to ſerve the purpoſe of reſpiration while it remains below.

The merganſers, from their voracity, and their expertneſs in ſwimming, are perhaps the moſt deſtructive of all birds that plunder the waters; while their fleſh, which is dry, and of a bad flavour, makes but a ſmall compenſation for the devaſtations which they commit.

Some of them build in trees; but the greater part in rocks, jutting over precipitous forelands. One or two ſpecies are ſaid to have been found as high up the North ſeas as Iceland, but this is uncommon. In all the ſpecies, the female is of a ſmaller ſize than the male, and differs conſiderably in the diſtribution of her colours. Her head is red; and the mantle or back and neck-feathers grey. The white nun is the moſt beautiful of the whole tribe; the white plumage of the fore parts, and the black mantle that covers its back, are each perfect in their kind; the tuft of ſmall detached feathers white upon the crown, but of a dark green ſhaded with purple upon the hind part, produces a very elegant effect; while to complete this modeſt and religious dreſs of the white nun, the lower part of the neck is half ſurrounded with a collar of long ſilky feathers like velvet.

Mergus *cirratus minor*, in *Ornithology*, a name by which Geſner calls the *capo negro*, a ſpecies of duck, called in Engliſh the *tufted duck*.

MERIANA, and Merianella, in *Botany*. See Antholyza and Watsonia.

MERIANIA, named by Swartz in memory of Maria Sybilla Merian, daughter of a German engraver, who was born at Frankfort on the Maine, April 12th 1647, and was the wife of John Andrew Graff. This lady is celebrated for her zeal in the purſuit of natural hiſtory, eſpecially in what relates to the metamorphoſes of inſects, and for her great ſkill in the uſe of the pencil. She publiſhed a work, of which there have been ſeveral editions, in folio or quarto, with plates, on European inſects, and the plants they feed upon; but her moſt famous book, detailing the metamorphoſes of Surinam inſects, is a ſplendid folio, of which original coloured copies are very rare and valuable. Botany was with her a ſecondary object, nor are her delineations, however magnificent, always remarkable for accuracy. She performed ſeveral voyages in purſuit of her favourite object. Sir Hans Sloane purchaſed what were ſuppoſed to be her original drawings on vellum, but the copy exhibited in the Britiſh Muſeum, has certainly marks of the graver, though it may have been coloured by her hand. She died at Amſterdam in 1717.—Swartz Ind. Occ. 823. Willd. Sp. Pl. v. 2. 600.—Claſs and order, *Decandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Melaſtomæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, campanulate, permanent, its margin in five, ſhort, obtuſe, membranous ſegments, each accompanied by a long, external tooth. *Cor.* Petals five, inſerted below the throat of the calyx, ovate, ſomewhat leathery, ſpreading, deciduous. *Stam.* Filaments ten, fixed internally to the five-ſided margin of the calyx, within the petals, broad at the baſe, bent in the upper part; anthers long, broadiſh, bent backward, pointed at the ſummit, opening there by two pores. *Piſt.* Germen ſuperior, roundiſh, five-ſided, in the bottom of the calyx; ſtyle thick, club-ſhaped, bent downward; ſtigma obtuſe. *Peric.* Capſule in the bottom of the bell-ſhaped calyx, covered by the calyx; but unconnected with it, naked above, roundiſh, five-ſided, five-celled, five-valved; the partitions contrary to the valves. *Seeds* numerous, minute. *Recept.* creſcent-ſhaped.

Eſſ. Ch. Calyx bell-ſhaped, five-cleft. Petals five, inſerted into the calyx. Stamens declining. Capſule diſtinct, of five cells; the partitions contrary to the valves. Seeds numerous.

1. M. *leucantha*. White-flowered Meriania. Swartz Ind. Occ. 826. t. 15. f. *a*. (Rhexia leucantha; Swartz Prod. 61.)—Leaves oblong, ſhining. Flowers with two bracteas.—Native of the higheſt mountains of Jamaica, flowering in the ſummer and autumn.—This is a ſhining, elegant *tree*, whoſe ſtraight *trunk*, covered with a ſmooth *bark*, is from 15 to 30 feet in height. *Branches* erect, roundiſh, ſmooth; ſmaller ones quadrangular, compreſſed, furrowed, brittle. *Leaves* oppoſite, croſſing each other in pairs, ovate-oblong, pointed, three-nerved, toothed and cartilaginous at the margin, paler, and beautifully veined like net-work beneath; ſmooth on both ſides; very ſhining, four or five inches long; on angulated ſmooth *footſtalks* which are channelled above. *Flower-ſtalks* at the axils of the terminal leaves, oppoſite, ſolitary, remote, an inch and a half long, round, compreſſed, erect, ſingle-flowered, ſmooth. *Bracteas* two, oppoſite, nearly ſeſſile, ovato-lanceolate, pointed, entire, three-nerved, pale. *Flowers* large and handſome, white, or ſlightly fleſh-coloured, inodorous, ſomewhat drooping.

2. M. *purpurea*. Purple Meriania. Swartz Ind. Occ. 829. t. 15. f. *b*. (Rhexia purpurea; Swartz Prod. 61.)—Leaves ovato-lanceolate. Flowers with four bracteas.—Grows in ſimilar ſituations to the laſt, and flowers in autumn. The preſent ſpecies differs chiefly from *M. leucantha* in being conſiderably ſmaller, in having its *leaves* of a browniſh-green, its ſmaller branches round, not quadrangular, and its *flowers* of a deep blood or purple colour, accompanied by four *bracteas* inſtead of two. The corolla in each ſpecies is as large as that of a ſingle wild roſe. We find the ſecond ſpecies, in the herbarium of the younger Linnæus, marked *Wrightia ſuperba*, and we recollect to have ſeen the ſame name at Sir Joſeph Banks's, which, when the genus was eſtabliſhed, ought to have been retained in juſtice to a very indefatigable collector and botaniſt who firſt ſent the ſpecimens to Europe, Dr. Wm. Wright, now of Edinburgh.

MERJAPOUR, in *Geography*, a town of Hindooſtan, in Bahar; 28 miles S.S.W. of Bahar.

MERIBASA, a river of Asiatic Turkey, which runs into the Mediterranean, near Adana.

MERICHSWAND, a fertile tract of Switzerland, in the canton of Luccon, four miles long, and two broad, separated from the rest of the canton. In it is a parochial village near the Rufz.

MERIDA, an ancient town of Spain, in Estramadura, seated on an eminence, near the Guadiana. It was anciently large, populous, and flourishing, and much embellished by the Romans, so that it now only presents an image of its former grandeur and magnificence. This town became a colony under the emperor Augustus, and being peopled, after the war with the Cantabrians, with soldiers of the 5th and 10th legions, took the name of that prince, and was called "Emerita Augusta." (See AUGUSTA.) Writers differ about its extent; some assigning to it eight miles, and others six leagues of circumference. It was, however, the largest in Spain, under the Romans. Under the dominion of the Goths, it preserved its monuments; but when it was taken by the Moors, A.D. 713, it was very much ransacked and destroyed. From them it was retaken by Alphonso IX., king of Castile and Leon, in 1230; and from that period it has been always attached to the kingdom of Castile. It lies in that part of Spain which the Romans called Vetonia; but notwithstanding its former extent and populousness, the number of its present inhabitants scarcely amounts to 5000. Under the Gothic kings it was the see of an archbishop, and the seat of some provincial councils. The archiepiscopal see was removed to Compostella by pope Calixtus II., under king Alphonso VII., whilst this town was in the possession of the Moors. When it was retaken by Alphonso IX., he gave it to the military order of St. James, and it still belongs to this order. Merida took as arms the reverse of a medal struck under Augustus for commemorating its erection into a Roman colony; this is a gate of a town formed by two arches with two towers, and a semicircular enclosure, which extended from one to the other. It still affords considerable wrecks of its ancient magnificence under the Romans. Here they built superb bridges and magnificent temples; triumphal arches and beautiful aqueducts; here they raised edifices for public feasts and games; a circus, a theatre, and a naumachia. The vestiges of these grand public monuments are still visible; of which some are in and others out of the town. The baths are in a better state of preservation than most of the other monuments. In its vicinity are two large reservoirs of water, resembling lakes, called Albafera and Albuera. One is 90 feet long, and 51 deep, surrounded by thick walls, and ornamented with two beautiful towers; about a league from the town. The other is at the distance of two leagues; it is small, but the walls which contain the waters, and the great tower which serves as an aperture for air, are much finer. The environs of Merida are pleasant and fertile; abounding in wine, good fruits, and grain, with excellent pasture; nine leagues from Badajoz. N. lat. 38° 48′. W. long. 6° 3′.

MERIDA, the capital of Yucatan, in the audience of Mexico; lying near the N. side of the province between the gulfs of Mexico and Honduras; the residence of a governor, and see of a bishop; 130 miles N.E. of Campeachy. N. lat. 21° 38′. W. long. 90° 36′.—Also, a town of South America, in the government of Caraccas, founded in 1558 by John Rodriguez Suarez, under the name of Santiago de los Caballeros, and situated in a valley three leagues long, and about three quarters of a league wide in its broadest part. It is surrounded by three rivers, Mucujun, Albarregas, and Chama, neither of which is navigable. At some distance from the city are plantations of sugar, cacao, and coffee. All the environs of Merida abound with fruits, maize, beans, peas, potatoes, cassada, wheat of the finest quality, barley, &c. Excellent meat is purchased here at a very moderate price. The climate is variable, so that every day it experiences the four seasons of the year. The west wind is particularly insalubrious; the rains are heavy, and fall through the year, but with peculiar violence from the month of March to November. This city is the see of a bishop and a chapter. It possesses a college and seminary for the education of ministers who conduct the Catholic worship; and for other classes of inhabitants. The orders of St. Dominic and of St. Augustin, and also of St. Clair, have each a convent; and besides the cathedral, they have several places of worship. The number of inhabitants at Merida amounts to 11,500, of all colours and of all classes. No class here disdains labour; the white are employed in agriculture, the rearing of cattle, and the offices of the ecclesiastical state. The people of colour fabricate different articles of cotton and wool. Merida is distant from Maracaibo 80 leagues to the S.; from Caraccas 140 leagues to the S.E., and from Varinas 25 leagues S.E. N. lat. 8° 10′. W. long. 73° 45′.

MERIDIAN, in *Astronomy*, a great circle of the sphere, passing through the zenith, nadir, and poles of the world, crossing the equinoctial at right angles, and dividing the sphere into two hemispheres, the one eastern, and the other western.

It is called meridian, from the Latin *meridies, noon,* or *mid-day,* because when the sun is in this circle, it is noon in those places situated under it.

MERIDIAN, in *Geography*, is a great circle, as P A Q D, (*Plate* I. *Geography*, *fig*. 9.) passing through the poles of the earth P and Q: and any given place at Z. So that the plane of the terrestrial meridian is in the plane of the celestial one.

Hence, 1, as the meridian invests the whole earth, there are several places situated under the same meridian. And, 2, as it is noon-tide whenever the centre of the sun is in the meridian of the heavens; and as the meridian of the earth is in the plane of the former; it follows, that it is noon at the same time, in all places situate under the same meridian. 3. There are as many meridians on the earth as there are points conceived in the equator. In effect, the meridians always change, as you change the longitude of the place; and may be said to be infinite; each respective place from east to west having its respective meridian.

MERIDIAN, *First*, is that from which the rest are accounted, reckoning from west to east. The first meridian is the beginning of longitude.

The fixing of the first meridian is a matter merely arbitrary; and hence different persons, nations, and ages, have fixed it differently; whence some confusion has arisen in geography. The rule among the ancients was, to make it pass through the place farthest to the west that was known. But the moderns knowing that there is no such place in the earth as can be esteemed the most westerly, the way of computing the longitudes of places from one fixed point is much laid aside.

Ptolemy assumed the meridian that passes through the farthest of the Canary islands as his first meridian; that being the most western place of the world then known. After him, as more countries were discovered in that quarter, the first meridian was removed farther off. The Arabian geographers chose to fix the first meridian upon the utmost shore of the western ocean. Some fixed it to the island of St. Nicholas, near Cape Verd; Hondius to the isle of St. James; others to the island of Del Corvo, one of the

Azores;

Azores; becauſe on that iſland the magnetic needle, at that time, pointed directly north, without any variation; and it was not then known that the variation of the needle is itſelf ſubject to variation. The lateſt geographers, particularly the Dutch, have pitched on the Pike of Teneriffe; others on the iſle of Palm, another of the Canaries; and, laſtly, the French, by command of their king, on the iſland of Ferro, another of the Canaries.

But, without much regard to any of theſe rules, our geographers and map-makers frequently aſſume the meridian of the place where they live, or the capital of their country, for a firſt meridian; and thence reckon the longitudes of their places.

The aſtronomers in their calculations uſually chooſe the meridian of the place where their obſervations are made, for their firſt meridian; as Ptolemy, at Alexandria; Tycho Brahe, at Uranibourg; Riccioli, at Bologna; Mr. Flamſteed, at the Royal Obſervatory at Greenwich; and the French, at the Obſervatory at Paris.

Meridian *of a Globe*, or *Sphere*, is the brazen circle in which the globe hangs and turns. See Globe.

It is divided into four nineties, or three hundred and ſixty degrees, beginning at the equinoctial: on it, each way, from the equinoctial, on the celeſtial globe, is counted the ſouth and north declination of the ſun or ſtars; and on the terreſtrial globe, the latitude of places north and ſouth. There are two points on this circle, called the *poles;* and a diameter, continued from thence through the centre of either globe, is called the axis of the earth, or heavens, on which they are ſuppoſed to turn round.

On the terreſtrial globes there are uſually thirty-ſix meridians drawn, one through every tenth degree of the equator, or through every tenth degree of longitude.

The uſes of this circle are, to ſet the globes to any particular latitude, to ſhew the ſun's or a ſtar's declination, right aſcenſion, greateſt altitude, &c.

Meridian *Line*, an arc, or part of the meridian of the place, terminated each way by the horizon.

Or, a meridian line is the interſection of the plane of the meridian of the place with the plane of the horizon, vulgarly called a *north and ſouth line,* becauſe its direction is from one pole towards the other.

The uſe of a meridian line in aſtronomy, geography, dialling, &c. is very great, and on its exactneſs all depends; whence infinite pains have been taken by divers aſtronomers to fix it to the utmoſt preciſion. M. Caſſini has diſtinguiſhed himſelf by a meridian line drawn on the pavement of the church of S. Petronio, at Bologna, the largeſt and moſt accurate in the world; being 120 feet in length. In the roof of this church, a thouſand inches above the pavement, is a little hole, through which the ſun's image, when in the meridian, falling upon the line, marks his progreſs all the year. When finiſhed, M. Caſſini, by a public writing, informed the mathematicians of Europe, of a new oracle of Apollo, or the ſun, eſtabliſhed in a temple, which might be conſulted, with entire confidence, as to all difficulties in aſtronomy. See Gnomon.

To draw a Meridian Line.—Knowing the ſouth quarter pretty nearly, obſerve the altitude F E (*Plate* XVII. *Aſtronomy, fig.* 3.) of ſome ſtar on the eaſtern ſide thereof, not far from the meridian H Z R N: then, keeping the quadrant firm on its axis, ſo as the plummet may ſtill cut the ſame degree, only directing it to the weſtern ſide of the meridian, wait till you find the ſtar has the ſame altitude as before, *f, e*. Laſtly, biſect the angle E C *e*, formed by the interſection of the two planes wherein the quadrant is placed at the time of the two obſervations, by the right line H R. This H R is a meridian line.

Or thus: on the horizontal plane, from the ſame centre C (*fig.* 4.) deſcribe ſeveral arcs of circles B A, *b a*, &c. and on the ſame centre, C, erect a ſtyle, or gnomon, perpendicular to the plane A C B, a foot or half a foot long. About the twenty-firſt of June, between the hours of nine and eleven in the morning, and between one and three in the afternoon, obſerve the points B, *b*, &c. A, *a*, wherein the ſhadow of the ſtyle terminates. Biſect the arcs A B, *a b*, &c. in D, *d*, &c. If then the ſame right line D E biſect all the arcs A B, *a b*, &c. it will be the meridian line ſought.

As it is difficult to determine the extremity of the ſhadow exactly, it is beſt to have the ſtyle flat at top, and to drill a little hole, noting the lucid ſpot projected by it on the arcs A B and *a b*, inſtead of the extremity of the ſhadow. Otherwiſe the circles may be made with yellow, inſtead of black, &c.

A good meridian line for regulating clocks and watches may be had by the following method: make a round hole, almoſt a quarter of an inch in diameter, in a thin plate of metal; and fix the plate in the top of a ſouth window in ſuch a manner, that it may recline from the zenith at an angle equal to the co-latitude of your place, as nearly as you can gueſs; for then the plate will face the ſun directly at noon on the equinoctial days. Let the ſun ſhine freely through the hole into the room, previouſly darkened; and hang a plumb-line to the ceiling of the room, at leaſt five or ſix feet from the window, in ſuch a place as that the ſun's rays, tranſmitted through the hole, may fall upon the line when it is noon by the clock; and having marked the ſaid place on the ceiling, take away the line. Having adjuſted a ſliding-bar to a dove-tail groove, in a piece of wood about eighteen inches long, and fixed a hook into the middle of the bar, nail the wood to the abovementioned place in the ceiling, parallel to the ſide of the room in which the window is; the groove and bar being towards the floor. Then hang the plumb-line upon the hook in the bar, the weight or plummet reaching almoſt to the floor: when this is done, find the true ſolar time, and thereby regulate your clock or watch. Then, at the moment of next noon by the clock, when the ſun ſhines, move the ſliding-bar in the groove until the ſhadow of the plumbline biſects the image of the ſun on the floor, wall, or on a white ſcreen placed on the north ſide of the line; the plummet, or weight at the end of the line, hanging freely in a pail of water, placed below it on the floor. By repeated corrections, on the following days, with the ſun and clock, this method may be brought to a very great exactneſs. This meridian line will not only be ſufficient for the regulation of clocks and watches, to the true mean time, by equation tables, but alſo for moſt aſtronomical purpoſes. Ferguſon's Lect. on ſelect Subjects, &c. lect. x.

Several authors have invented particular inſtruments and methods for the deſcribing of meridian lines, or rather for determining equal altitudes of the ſun in the eaſtern and weſtern parts of the heavens; as Mr. Grey, Dr. Derham, &c. in the Philoſophical Tranſactions. But as the former of the methods above delivered ſuffices for aſtronomical obſervations, and the latter for more ordinary occaſions, we ſhall forbear to give any deſcriptions of them.

From what has been ſhewn, it is evident, that whenever the ſhadow of the ſtyle covers the meridian line, the centre of the ſun is in the meridian; and, therefore, it is then noon. And hence the uſe of a meridian line in adjuſting the motion of clocks, &c. to the ſun.

Hence

Hence also, if the meridian line be bisected by a right line O V, drawn perpendicularly through the point C, O V will be the intersection of the meridian, and first vertical; and, consequently, O will shew the east point, and V the west.

Lastly, if a style be erected perpendicularly in any other horizontal plane, and a signal be given when the shadow of the style covers the meridian line drawn in another plane, noting the apex, or extremity, of the shadow projected by the style, a line drawn from that point through that wherein the style is raised, will be a meridian line.

One meridian line being given, another may be drawn upon another horizontal plane by the following method: hang a thread with a plummet exactly over the south end of the meridian line given, and another thread with a plummet over the south end of the plane upon which the meridian line is to be drawn; let one person observe at noon the moment when the shadow of the first thread falls exactly upon the meridian given, and let another observer, at the same time, mark two distant points in the shadow of the second thread: a line drawn through those points is the meridian line required. By the same method may a meridian line be found upon a south wall, by making two points in the shadow of a thread hung at a little distance from it: if the meridians are near, he, that observes the shadow of the first thread, may let the other know the moment it falls upon the meridian line, by saying *now*: if they are far distant, it should be done by the motion of the hand, because sound takes some time to pass from one place to another. The meridian line is the basis of astronomical observations: a meridian line being found, there may be placed over it a quadrant or sextant in such a manner, that though it be moved up or down to give it different elevations, in order to view through the sights of it the celestial bodies at their different altitudes; yet the plane of that side of the instrument upon which the degrees are marked shall continue all the while in the plane of the meridian. Of this kind is the mural arc in the royal observatory at Greenwich. See MERIDIAN *Altitude*.

MERIDIAN *Line*, on a dial, is a right line arising from the intersection of the meridian of the place with the plane of the dial. This is the line of twelve o'clock, and from hence the division of the hour-line begins.

MERIDIAN, *Magnetical*, is a great circle, passing through or by the magnetical poles; to which the magnetic needle, or needle of the mariner's compass, if not otherwise hindered, conforms itself.

MERIDIAN *Altitude* of the sun or stars is, their altitude when in the meridian of the place where they are observed. See ALTITUDE.

To take the Meridian Altitude of the Stars.—Astronomers make two principal kinds of observations of the stars, the one when they are in the meridian, and the other when in vertical circles.

For meridian observations there are two instruments principally used, the quadrant and gnomon.

To take the Meridian Altitude with a Quadrant.—If the position of the meridian be known, and the plane of an astronomical quadrant be placed in the meridian line, by means of the plumb-line suspended at the centre, the meridian altitudes of the stars, which are the principal observations whereon the whole art of astronomy is founded, may easily be determined.

The meridian altitude of a star may likewise be had by means of a pendulum-clock, if the exact time of the star's passage by the meridian be known. Now it must be observed, that the stars have the same altitude for a minute before and after their passage by the meridian, if they be not in or near the zenith; but if they be, their altitudes must be taken every minute, when they are near the meridian; and then their greatest altitudes will be the meridian altitudes sought.

As to the manner of observing, it is found very difficult to place the vane of the quadrant in the meridian exact enough to take the meridian altitude of a star; for, unless there be a convenient place, and a wall, where the quadrant may be firmly fastened in the plane of the meridian, which is not easily had, we shall not have the true position of the meridian proper to observe the stars. It will be much easier, therefore, on several accounts, to use the portable quadrant, by which the altitude of the star may be observed a little before its passage over the meridian, every minute, till its greatest altitude be found. Here, though we have not the true position of the meridian by this means, yet we have the apparent meridian altitude of the star.

Though this method, in the general, be very good, and free from any sensible error; yet, in case a star passes by the meridian near the zenith, it proves somewhat defective: for in these kinds of observations, the inconvenient situation of the observer, the variation of the star's azimuth several degrees in a little time, the alteration of the instrument, and the difficulty of replacing it vertically, will prevent the observations being made oftener than in every four minutes; but in each minute the altitude varies about 15 minutes of a degree, so that there will be the difference of a degree in the star's altitude between each observation. In such cases, therefore, it will be better to have the true position of the meridian, or the exact time wherein the star passes the meridian, in order either to place the instrument in the meridian, or to observe the altitude of the star the moment it passes the meridian.

To find the Meridian Altitude of the Sun, &c. by a Gnomon, see GNOMON. By other means, see ALTITUDE.

MERIDIAN *Telescope*. See TELESCOPE.

To measure the Degrees of the Meridian, see DEGREE.

To observe the Transits or Passages of the heavenly Bodies across the Plane of the Meridian.—A meridian line being found, hang two threads with plummets exactly over it, at a little distance from one another, and they will be in the plane of the meridian: if you place your eye close to one of the threads in such a manner that you make it cover the other, and both appear as one thread; when a star is behind the threads, it is in the meridian. By the same method the sun may be viewed through a smoaked glass; when the threads pass through his centre, he is in the meridian: but the best way of observing the sun, moon, stars, or planets, is through a telescope placed in the meridian, with two cross hairs, one of which is in a vertical, the other in a horizontal position; when the vertical hair passes through the centre of the sun, he is in the meridian.

MERIDIAN, from *Meridies*, the hour for sleeping, which was allowed to the ancient monks, in this and other countries, about noon, during the summer months.

MERIDIANI, in *Antiquity*, is a name which the Romans gave to a kind of gladiators, who entered the arena about noon, after the bestiarii (who fought in the morning against beasts) had finished. See GLADIATOR.

They were thus called from *meridies*, i. e. *noon*, the time when they exhibited their shows.

The meridiani were a sort of artless combatants, who fought man with man, sword in hand: hence Seneca takes occasion to observe, that the combats of the morning were full of humanity, compared with those which followed.

MERIDIONAL Distance, in *Navigation*, the fame with departure, or eafting and wefting; being the difference of longitude between the meridian, under which the fhip now is, and any other meridian, which fhe was under before.

Meridional *Parts*, *Miles*, or *Minutes*, are the parts by which the meridians in a Mercator's chart increafe, as the parallels of latitude decreafe.

The cofine of the latitude of any place being equal to the radius, or femidiameter, of that parallel; therefore, in the true fea-chart, or nautical planifphere, this radius being the radius of the equinoctial, or whole fine, of 90 degrees, the meridional parts at each degree of latitude muft increafe, as the fecants of the arc contained between that latitude, and the equinoctial decreafe.

In order to underftand this, it is neceffary to confider, 1. That the diftance between any two meridians at the equator is to their diftance in any parallel of latitude as radius is to the cofine of that latitude. Let P D F E (*Plate* I. *Navigation*, *fig*. 8.) reprefent the fourth part of a fphere; E being the centre, P the pole, E D the radius of the equator, A B the radius of a parallel of latitude: then each of the arcs P B D, P C *d*, will reprefent a quadrant of a meridian; D *d* an arc of the equator; and B C an arc of a parallel of latitude: D B expreffes the latitude, and P B the complement of the latitude, whofe right fine is B A. But the circumference of a circle, whofe radius is E D, is to the circumference of a circle, whofe radius is A B, and confequently like arcs D *d*, B C, intercepted between the fame two meridians, as E D is to A B, *i. e.* as radius to the cofine of the latitude. Whence it is eafy to conftruct a table fhewing in what proportion the degrees of longitude diminifh in every latitude. See fuch a table under article Degree *of Latitude*.

2. Any part of a parallel of latitude is to a like part of a meridian, as radius is to the fecant of the latitude of that parallel. Let P D E (*Plate* I. *Navigation*, *fig*. 9.) reprefent a quadrant of a meridian, where P is the pole, and D E the radius of the equator; A B is the radius of a parallel of latitude, or the cofine of the latitude, whofe fine is B F, and fecant E C. Then E F : E B :: E D : E C; or cofine latitude : rad. : : rad. : fecant of the latitude, in that parallel. Therefore, part of a parallel of latitude is to a like part of the equator as the radius is to the fecant of the latitude to that parallel: confequently, fince like parts of the meridian and equator are equal, as great circles, any part of a parallel of latitude is to a like part of a meridian, as radius to the fecant of the latitude to that parallel.

3. The diftance of any parallel of latitude, A, from the equator, is expreffed by the fum of the fecants of all the arcs between the equator and that parallel. For, as radius to the fecant of the latitude A, fo is a diminifhed degree of longitude in the latitude A, or a degree of that parallel, to a degree of the meridian: but the degrees of latitude, or of the meridian, are to be lengthened in proportion as the degrees of longitude decreafe: therefore, as radius to the fecant of the latitude A, fo is a natural degree of the meridian to a lengthened degree in the latitude A, radius being here as unity, and one natural degree as unity alfo: therefore, the length of a degree in any latitude is as the fecant of that latitude, or may be expreffed by that fecant: but the diftance of any parallel from the equator is the fum of all the fucceffive arcs between the equator and that parallel: confequently, the diftance of that parallel is expreffed by the fum of the fecants of all thefe arcs between the equator and that parallel of latitude: and, therefore, by the addition of the fecants of fmall arcs, the diftances of the parallels of latitude from the equator are obtained.

The tables, therefore, of meridional parts, in books of navigation, are to be made by a continual addition of fecants, calculated in fome books, as in fir Jonas Moor's Tables, Robertfon's Navigation, &c. for every degree and minute of latitude; and thefe will ferve either to make or graduate a Mercator's chart, or to work the Mercator's failing.

Mr. Wright, to whom we are indebted for this excellent difcovery, made his table for the divifion of the nautical meridian, or the table of meridional parts, as follows: the meridional parts for 1 minute he made equal to the fecant of 1 minute; thofe of 2′ equal to the fum of the fecants of 1′ and 2′; thofe of 3′ equal to the fum of the fecants of 1′, 2′, and 3′; thofe of 4′ equal to the fum of the meridional parts of 3′ and the fecant of 4′; and fo on by a conftant addition of the fecants: Mr. Oughtred, fir Jonas Moor, Dr. Wallis, Dr. Halley, and others, have endeavoured to find methods of conftructing thefe tables with greater accuracy than by the addition of the fecants to every minute. As the reader may not have immediate accefs to fuch a table, we have here annexed one, extracted from Robertfon's "Elements of Navigation."

The following is a Table of meridional parts to every degree and minute of the quadrant, eftablifhed on a fuppofition that the earth is a perfect fphere.

min.	M. P.	M. P.	M. P.	M. P.	M. P.	M. P.	M. P.	M. P.	M. P.	M. P.	M. P.	M. P.	min.
D. L.	78	79	80	81	82	83	84	85	86	87	88	89	D. L.

N.B. In this table D. l. ſtands for degree of lat. and M. P. for meridional parts. In uſing it, ſeek the degrees of latitude at the top or bottom, and the minutes in the right or left hand columns; and the correſponding meridional parts will ſtand right againſt the minutes, and in the column ſigned with the degree propoſed.

Having the latitude of two places, to find the meridional miles or minutes between them; conſider whether the places be one under the equinoctial, and the other wide of it; or the one on the one ſide of the equinoctial, and the other on the other; or whether they both lie on the ſame ſide.

If one place lie under the equator, the meridional minute next under the degree of latitude of the other place, is the meridional difference of latitude, or latitude enlarged. If one be in north, and the other in ſouth latitude, the meridional minutes, correſponding to the two latitudes, added together, give the meridional minutes between them.

Both places lying towards the ſame pole, ſubtract the meridional parts anſwering to the leſs latitude from thoſe of the greater, the remainder gives the meridional minutes. See Sailing.

In the Philoſophical Tranſactions, No. 219, Dr. Halley has given a very curious paper relating to the diviſion of the nautical meridian, by a quite different method from Mr. Wright's; and containing a method of performing the problems of ſailing according to the true chart, by the help of Briggs's, or the common table of logarithmic tangents, without a table of meridional parts. Dr. Halley avails himſelf of a principle, firſt accidentally diſcovered by Mr. Henry Bond, and publiſhed about the year 1645, that the meridian line was analogous to a ſcale of logarithmic tangents of half the complements of the latitude. This analogy was firſt demonſtrated by Mr. James Gregory, in his "Exercitationes Geometricæ," publiſhed in 1688, and more elegantly and conciſely by Dr. Halley himſelf; who has alſo ſhewn (ubi ſupra) how to apply this analogy, by means of any ſyſtem of logarithms, for computing the interval of the meridional parts anſwering to any two given latitudes. The reader may find this ſubject well illuſtrated by Mr. Robertſon in his Elements of Navigation, book viii. p. 142, &c. See alſo Phil. Tranſ. vol. xlvi. p. 559, &c.

To find the meridional parts to any ſpheroid, with the ſame exactneſs as in a ſphere.

Let the ſemi-diameter of the equator be to the diſtance of the focus of the generating ellipſe from the centre, as m to 1. Let A repreſent the latitude for which the meridional parts are required, s the ſine of the latitude, the radius being unit; find the arc B, whoſe ſine is $\frac{s}{m}$; take the logarithmic tangent of half the complement of B, from the common tables; ſubtract this logarithmic tangent from 10.0000000, or the logarithmic tangent of 45°: multiply the remainder by $\frac{7915.7044678978}{m}$, &c. and the product ſubtracted from the meridional parts in the ſphere, computed in the uſual manner for the latitude A, will give the meridional parts expreſſed in minutes for the ſame latitude in the ſpheroid, provided it be oblate.

Example:—If $mm : 1 :: 1000 : 22$, then the greateſt difference of the meridional parts in the ſphere and ſpheroid is 76.0929 minutes; in other caſes it is found by multiplying the remainder above mentioned by 1174.078.

When the ſpheroid is oblong, the difference of the meridional parts in the ſphere and ſpheroid, for the ſame latitude, is then determined by a circular arc. Phil. Tranſ. No. 461. ſect. 14. See alſo Maclaurin's Fluxions, art. 195—899.

Mr. Murdoch has ſolved this problem by infinite ſeries, and has computed a table of meridional parts for an oblate ſpheroid, ſuch as is mentioned in the foregoing example. See his treatiſe, intitled "Mercator's Sailing applied to the true Figure of the Earth," Lond. 1741, 4to. See the article Degree.

MERJEIAH, in *Geography*, a town of Algiers; 80 miles E. of Oran.

MERIGHI, La Signora, in *Biography*, was announced in Handel's advertiſements, on his return from Italy in 1729, where he had been to engage ſingers, as "a woman of a very fine preſence, an excellent actreſs, and a very good ſinger, with a counter-tenor voice." We find afterwards, however, that ſhe was only engaged as ſecond woman under the Strada.

MERJIAN, in *Geography*, a town of Perſia, in the province of Kerman; 55 miles N. of Kabis.

MERIM, a large lake of S. America, in Paraguay, near the coaſt of the S. Atlantic ocean. At the S. end ſtands fort St. Miguel, and at its northern extremity fort Mangaveira. Parallel to it, and between it and the ocean, is another lake nearly as long. The forts command the extremities of the peninſula.

MERIMEG, or Maramag, a large river of Louiſiana, which runs into the Miſſiſippi, below the mouth of the Miſſouri.

MERINDAPILLY, a town of Hindooſtan, in Baramaul; 25 miles N.W. of Darempoury.

MERINO-Sheep, in *Agriculture*, a breed of fine-woolled ſheep lately introduced from Spain, hence ſometimes termed the *Spaniſh breed.* They are characteriſed by the males having horns, but the females being ſometimes without them, by having white faces and legs, the latter rather long, the body not very perfect in ſhape, fine in the bone, ſome degree of thrc[illegible]tineſs, the pelt fine and clear. The weight, when fattened in ſome degree, in the rams about 17lbs., in the ewes 11lbs. the quarter. The wool is very fine. They are ſaid to be hardy, and to have the property of fattening in a pretty expeditious manner. See Mesta, and Sheep.

MERION, Upper and Lower, in *Geography*, two townſhips of America, in Montgomery county, Pennſylvania; the firſt has 993, and the latter 1422 inhabitants.

MERIONETHSHIRE, one of the counties of North Wales, is bounded on the W. by the extenſive bay of Cardigan, which forms part of the Iriſh ſea; on the N. by Denbighſhire and Caernarvonſhire; on the E. by Montgomeryſhire; and on the S. by the river Dovey, which divides it from Cardiganſhire. This county extends in length, from Beddgelert, near Snowdon, to Bwlch y Vedwen, on the confines of Montgomeryſhire, 43 miles; in breadth, from Harlech to the extreme boundary of Llangollen pariſh, 38. It is called by the natives Meironydd, and is the only county in Wales which, with the addition of the word ſhire, ſtill retains its ancient appellation. This name is ſaid to be derived from Meirion, the ſon of Tibrawn, and grandſon of Cunedda, a diſtinguiſhed Britiſh chieftain of the fifth century, who, having aſſiſted the Welſh in reſcuing their country from the depredations of a band of Iriſh marauders, received from them a large extent of territory as the reward of his ſervices.

The early hiſtory of this county is equally as obſcure as that of any other in Wales. That it was known to the Romans is evident from the many veſtiges of their cuſtoms which are yet to be diſcovered in different parts of it. Of theſe the

the principal are, the fortifications of Tommen-y-Bala, near Bala town; Caer-Gai, in the vicinity of Llanuwchllyn; Cefn-Caer, in the parifh of Penul, and Tommen-y-Mur, near Feftiniog. The Roman road, denominated Sarn-Helen, can eafily be traced from the fine ftation laft mentioned, ftretching itfelf towards Dinas Emryfm, Caernarvonfhire. From this road two branches appear to have ftruck off in this neighbourhood, one of which led to Conovium, and the other to Segontium. During the Saxon and Norman dynafties, hiftory is nearly filent concerning Merionethfhire, but the numerous fortifications which cover its hills plainly evince that it did not in thefe ages efcape the ravages of war. At a later period it was the fcene of many of the daring exploits of the celebrated Owen Glyndyr, who fo vigoroufly efpoufed the caufe of the unfortunate Richard II.

The general afpect of Merionethfhire differs in fome refpects from that of the other counties in North Wales. For the moft part it is extremely mountainous, but its mountains are lefs elevated, with the exception of a few points, than thofe of the adjacent county of Caernarvon. The higheft hill, however, called Cader-Idris, is inferior in height only to Snowdon. This mountain, according to tradition, was fo called from being the favourite feat of Idris, who was a great prince, poet, aftronomer, and philofopher in ancient times. Its higheft peak is faid to be two thoufand eight hundred and fifty feet above the level of the town of Dolgellau, which is fituated near its bafe. The other principal eminences are Aren-Vowdhwy, Aren-Benllyn, Arennig, Moelwyn, Manod, &c.: thefe rear their lofty heads over a profufion of lower hills, which are interfected by fome beautiful vallies, and are interfperfed with woods, lakes, rivers, rivulets, and cataracts.

The principal river in this county is the Dee, which takes its rife from feveral fprings on the declivity of the lofty Aren. Thefe quickly uniting their ftreams enter the lake, called by the Welfh Llyn-tegid, and by the Englifh Pimblemeer, and from thence flow through the beautiful vale of Edernion, towards Corwen, a little below which town it enters Denbighfhire. The Dee, in its courfe through this county, forms feveral fine cataracts. That called Rhaiadrdu, or the Black-Cataract, from the colour of its waters, is fituated in the vicinity of Dolgellau, and is a double fall about fixty feet in height, where the river dafhes rapidly over a feries of black rugged rocks, which are covered in many places with white lichens, and thus give a peculiar appearance to the fcene. The other rivers of importance befides the Dee are the Maw or Mawddach, the Dovey or Duff, and the Glaflyn and Dwy'rid, the two laft of which form a junction, and paffing Traeth-Mawr and Traeth-Bychan, empty their waters into the Irifh fea. There is in this county a variety of lakes: the principal ones are Llyn-tegid near Bala, and Llyn Talyllyn at the fouthern foot of Cader Idris.

From the mountainous nature of Merionethfhire it may naturally be fuppofed that it is not deftined to reach any high degree of agricultural improvement. Mr. Davies, in his enlightened Survey of North Wales, eftimates the number of acres in the whole county at 430,000, and ftates that out of thefe not above 146,000 acres are inclofed. The foil is various, but in general extremely poor. The hilly diftricts, where covered with foil, are in general too fteep and rugged to admit of culture. By far the greater proportion of the low grounds confifts of peat earth, forming bogs and turbaries. In fome few places attempts have been made by different individuals to bring a part of thefe wafte lands into cultivation, but their progrefs has by no means anfwered their expectations, though fome advantages have certainly been gained. The attention of the inhabitants therefore is chiefly directed to the rearing and feeding of cattle, fheep, and goats, of which a great number are exchanged for the commodities of more fertile, or more commercial diftricts. The cultivated fpots lie chiefly on the fea-coaft, and on the fkirts of the county. In the vallies, and on the fides of the hills, in many parts there appear confiderable plantations of wood, both natural and raifed by art.

Notwithftanding the apparently favourable character of this county for the productions of the mineral kingdom, it is remarkable that few mines of any importance have been difcovered in it. The diftrict abounds indeed with numerous veins, both of lead and copper ore, but they are generally either fo peculiarly placed, or fo limited in extent, as to deprive the adventurer of any fair profpect of remuneration for the expence and trouble of opening them. Sulphat of copper, in particular, is found at Aberdyfo, and at Buddugre and Clogiau mines near Dolgellau. The two latter are the principal in Merionethfhire, and perhaps the only ones which are wrought with any degree of fpirit or profit. At Moel-Ifbri, in the parifh of Llanellyd, Pont-yr-avonddu, Bulch-y-plwm, and Craig-wen, near Dinas-mowddwy, are the chief veins of lead. The fame metal alfo abounds at Melin, Illyw-y-pair, in the parifh of Tywyn, and at Bryndinas, near Dyffryn-gwyn.

This county poffeffes no iron ores, and can only boaft of one infulated white lime rock at Gwerclas, near Corwen, in which about 50,000 bufhels are annually burnt. Merionethfhire affords no coal, fo that peat forms the chief article for fuel.

But if the practical miner does not difcover here fuch exhauftlefs ftores of ufeful metals as he might be led to expect upon a general view of the county, the fcientific mineralogift will find ample materials for the illuftration of his geological inquiries. The lofty mountain of Cader-Idris poffeffes numerous peculiarities, both of ftructure and compofition; and affords feveral facts tending to fupport the Huttonian hypothefis. This eminence is the commencement of a chain of primitive mountains, which extend in a north-north-eafterly direction towards the Arens and Arrenig. It is extremely fteep, and more craggy than the hills of fecondary formation which furround it, and confifts of filiceous porphyry, quartz, and feldfpar, inclofed in a green pafte, with filiceous fchiftofe porphyry, interfected with veins of quartz and argillaceous porphyry in a mafs, and a dark grey pafte. Befides thefe fpecies, fome of the rocks likewife contain the component parts of granite and porphyry, together with the granitell in mafs of Mr. Kirwan, compofed of quartz and fchorl. On the fides of the mountain lie a confiderable quantity of ftones, refembling lava; and hence fome writers fuppofe it to have been at one time volcanic. But this fuppofition is unqueftionably erroneous. The porous appearance of thefe ftones has arifen from the circumftance of the feldfpar which interfected the quartz having been decompofed. On the fouth fide of the mountain, and near its apex, is a large lake, from which the rocks rife almoft perpendicularly. On the north fide is another lake: and at the fummit is a mafs of large ftones, called Idris's chair. See Aikin's Tour in Wales.

In a level part of the county, called Towyn Meironydd, rifes a very fingular rock of immenfe fize, and terminating in a conical form. Quartz conftitutes the chief matrix of the lead and copper ores here. In fome places feveral veins confift entirely of this mineral upon the furface. A line of dark coloured argillaceous limeftone can be traced in a fouthweftern direction, ftretching through the whole extent of the

the county to Cadair-Ddinmael, near Cerrig-Druidion. This lime is of little value, either as a cement or a manure.

Besides the Roman roads already mentioned, Merionethshire contains many interesting monuments of remote ages. Above Nannua, in the neighbourhood of Dolgellau, on a rocky eminence, is a vast collection of loose stones, which have evidently formed the rampart of a British post. The hill on which these stones are placed is emphatically denominated Moel-orthrwm, or the hill of oppression. The remains of a castle, formerly of great strength and extent, occupy the top of the insulated rock near Towyn-Meironydd, already noticed. It appears to have stretched longitudinally over the whole surface of the summit. One of the apartments, thirty feet in diameter, is excavated in the rock. In some parts, the lines of circumvallation consist of stones loosely piled on the edges of the precipices; but on other parts appear well built walls of squared stones, cemented with mortar composed of calcined shells and gravel. According to Mr. Pennant, this castle was anciently called Castle-bere, and was granted by Edward I. to the custody of Robert Fitzwalter. The same author likewise supposes, from its present name Teberri, that it may have been the fortress belonging to the last Llewellin, which was taken only a short time previous to the final conquest of Wales by William de Valence, earl of Pembroke. This conjecture, however, is extremely questionable. St. Cadwan's stone, in the church-yard of Towyn, is traditionally reported to have been erected, in honour of that saint, in the sixth century. In the parish of Llanelltyd are the ruins of Cynmer-abbey, founded by two Welsh princes in 1198. On the mountain called Mikneint, near Rhyd-ar-Helen, stand some remarkable stone monuments, at least thirty in number. Each separate grave has four stones, one at each corner, resembling small square pillars, two or three feet high, and about nine inches broad. Tradition says they serve to commemorate some persons of note, who fell in the battle fought here between the men of Dyffryn-Ardwdwy, and some of Denbighshire. A considerable number of similar monuments are found likewise in the parish of Trawsfynudd. Several stone circles appear in the vicinity of these graves, the largest about fifty-two feet in diameter, and a vast carnedd, with two upright stones; also several smaller circles, the whole apparently surrounded by one of much greater circumference. Near Rhuw-goch is a small fort, in a singular position, on a circular isolated rock, resembling an artificial mount, between the hills, evidently intended for the defence of the pass. Some persons have supposed that this was of British construction, but the regularity of its facings, and the numerous coins which have been found in its neighbourhood, seem to imply that it was of Roman formation. Besides, in the inclosed country immediately adjacent, is a large encampment, undoubtedly the work of that illustrious people. This commands a variety of passes, which are defended by minor posts. At one extremity of the vale of Maentwrog is a large upright stone, called Maen-twrog, which is supposed to be the monument of a saint so named, who was contemporary with St. Beuno. The large artificial mount called Tomen-y-Bala, near the lake of Bala, is supposed to have been originally Roman, but afterwards to have been occupied by the Welsh during their conflicts with the English. Situated on an eminence fronting the town of Corwen, is the British post called Caer-Drewin, which consists of a circular wall, about a mile and a half in circumference, and is supposed by Mr. Pennant to have been one of those strong holds in which the Welsh secured their families and their property, in the event of an invasion. Lyttelton conjectures that Owen Gwynnedd occupied this post, while Henry II. encamped on the opposite side of the vale, from whence however he was forced to return to England in chagrin, without being able to strike a single blow. It was afterwards the retreat of the brave and heroic Owen Glyndwr, whose memory continues to be highly revered by the inhabitants of the surrounding district. Harlech castle has been already described under the word HARLECH. This county is not distinguished for its manufactures; but at Bala and Dolgellau, some strong cloths, druggets, kersimeres, flannels, &c. are made. Bala is particularly noted for its stockings and wigs.

The political divisions of this county have varied at different periods. At present it comprehends five comots, or hundreds, *viz.* Ardwdwy, Penllyn, Estumaner, Edernion, and Talybont; 37 parishes, and seven market-towns; *viz.* Harlech, Bala, Dolgellau, Dinas-y-Mowddu, Corwen, Tywen or Towyn, and Barmouth. Harlech, the county-town, is but a poor place, though governed by a mayor. Barmouth is the only port in the county. Dolgellau is distinguished as the place where the summer assizes are held, and is perhaps the most thriving town in Merionethshire. Bala is likewise a thriving town. Dinas-Mowddu, although now a mean town, was anciently a fortified city, and the residence of a Welsh prince or chieftain. It is still a corporate town, with a mayor, alderman, recorder, and several burgesses. The mayor has the right of trying criminals, but of late years that privilege has not been put in practice. He still, however, retains all the insignia of his magisterial office. Besides these towns there is a variety of villages dispersed through different parts of the county. Of these, Festiniog and Mallwyd are remarkable for the beauty of their situations, and noble prospects which they command. Festiniog has been celebrated by several authors, but more especially by lord Lyttelton. The vale in which this stands has been compared to the celebrated vale of Tempe, and it must be confessed that few spots in this island can boast of such varied and romantic scenery.

According to the parliamentary return of 1801, this county contained 5980 houses, and 29,506 inhabitants, of whom 13,896 were males, and 15,6 o females. The number engaged in agriculture was 10,308, and in commerce and manufactures 2711. Pennant's Tour in Wales. Carlisle's Topographical Dictionary of Wales. Aikin's Tour in Wales.

MERIS, μερις, *a part*, in *Music*, an appellation given by Mr. Sauveur to the forty-third part of an octave. See Mem. Acad. Scienc. 1701.

MERISMA, in *Botany*, from μερισμος, *a division*, alluding to the divided or branched nature of this fungus.—Pers. Syn. 582.—Class and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eff. Ch. Branching, leathery, compressed, even; for the most part hairy at the top.

This genus consists of seven species in Persoon, differing from *Clavaria* chiefly in their compressed dilated form, for the hairiness is avowedly not constant. Examples may be seen in

M. *cristatum*. Pers. n. 3. (Clavaria laciniata; Bull. t. 415. f. 1. Sowerb. t. 158.)—Somewhat decumbent, incrusting other plants, pale; its branches laciniated, tumid, rugose. Found in woods, running over every thing that comes in its way, like a stalactitical concretion, and throwing out variously dilated, sharply jagged, fan-like branches. The whole is of a pale whitish hue, and faint smell and taste.

M. *fœtidum*. Pers. n. 7. (Clavaria anthocephala; Bull. t. 452. f. 1. Sowerb. t. 156)—Purplish-brown. Branches palmate, crowded, whitish and polished at their tips.—Not unfrequent on the ground in fir woods. It is of a tough

woody

woody texture, and about two inches high, of a nauseous scent when fresh. The whole is of a palmate figure, stalked, with many crowded, fan-like *branches*, various in diameter, whitish at their summits, which are abrupt and notched.

MERIT, in *Theology*, is used to signify the moral goodness of the actions of men, and the reward due to them.

The Romish schoolmen distinguish two kinds of merit towards God: the one of *congruity*, the other of *condignity*.

MERIT *of Congruity* is when there is no just proportion between the action and the reward; but he who bestows the reward supplies, by his goodness or liberality, what was wanting in the action. Such is the merit of a son towards his father: but this is only merit in an improper sense.

MERIT *of Condignity* is when there is an absolute equality and a just estimation between the action and the reward: as in the wages of a workman.

Those of the reformed religion disclaim all merit of condignity towards God; even their best works, they own, do not merit at his hands. Hence the doctrine of condign merits makes one of the great articles of controversy between the Romish and reformed churches.

MERIT, *Order of*, was instituted by Frederick, king of Prussia. The ensign of the order is a star of eight points enamelled blue, and edged with gold; on the centre the letters F.R. in a cypher; in each angle an eagle displayed sable; on the upper two points, the regal crown of Prussia; on the reverse, in enamel, this motto, POUR LE MERITE. It is worn round the neck, pendent to a black ribbon, edged with silver.

MERIT, *Military Order of*, in Hesse Cassel, was instituted by the late landgrave. The badge is a gold star of eight points enamelled white; on the centre this motto, VIRTUTE ET FIDELITATE. It is worn at the button-hole, pendent to a blue ribbon, edged with silver.

MERIT, *Military, the Order of*, was instituted in France, in the year 1759, by Louis XV. in favour of those officers of his army who were Protestants. The marks of honour are the same with those of the order of *St. Louis*. The ensign of the order is also of the same form as that of St. Louis, with this difference, that on one side is "a sword in pale," within this motto, PRO VIRTUTE BELLICA: and on the reverse is a chaplet of laurel: within this inscription, LUD. XV. INSTITUIT, 1759.

MERKA, in *Geography*, a town of Prussia, in the palatinate of Culm; 10 miles N.N.E. of Thorn.

MERKENDORF, a town of Germany, in the margravate of Anspach; 7 miles S.E. of Anspach.

MERKET ISLANDS, a cluster of small islands in the Red sea, near the coast of Arabia. N. lat. 18° 10′.

MERKLIN, a town of Bohemia, in the circle of Pilsen; 15 miles S.S.W. of Pilsen.

MERLANGUS, in *Ichthyology*, a name given by Bellonius and some other authors, to a small species of whiting, or *asellus mollis*, called by the Venetians *mollo*, and by some other nations the *capelon*. See GADUS *minutus*.—Also, the name of the common whiting, a species of *Gadus*; which see.

MERLENGO, in *Geography*, a town of Italy, in the department of the Mincio; 10 miles N. of Mantua.

MERLERA, a small island in the Mediterranean, four miles from cape Sidero, on the N. coast of Corfu.

MERLERAULT, a town of France, in the department of the Orne, and chief place of a canton, in the district of Argentan; 18 miles N.N.E. of Alençon. The place contains 1222, and the canton 8098 inhabitants, on a territory of $177\frac{1}{2}$ kiliometres, in 19 communes.

MERLIN, AMBROSE, in *Biography*, a British writer, who flourished in the fifth century, was regarded as a prophet and magician. Strange stories are told of him by ancient writers, some of whom have assumed that he conveyed by enchantment the stupendous stones on Salisbury plain from Ireland. There are likewise certain extravagant predictions that pass under his name, printed at Paris in 1530. Near Caermarthen is a mount called Merlin's Hill, beneath which it is said the prophet was buried.

MERLIN, in *Ornithology*, the name of the yellow-legged falcon. See FALCO *Æsalon*.

MERLINGEN, in *Geography*, a town of Switzerland, in the canton of Bern; 7 miles S.E. of Thun.

MERLOM, a town of Hindoostan, in Dowlatabad; 12 miles S.E. of Bader.

MERLON, in *Fortification*, that part of the parapet, from fifteen to eighteen feet in length, which lies betwixt two embrasures.

The word comes from *merula*, or *merla*, which, in the corrupt Latin, was used for a battlement.

To stake out the merlons, measure from each end of the wall, twelve feet, there stick a stake, and plant other stakes at every intermediate eighteen feet: when this is done on the inside of the wall, let other stakes be planted on the outside, either directly opposite to the former, or in the line towards the place where the gun is more particularly intended to deliver its shot. Plant other stakes on the inside, one a foot distant on each side of the former, and this will leave spaces of two feet each for the inner opening of embrasures: then, on the outside, plant other stakes at five or six feet distance from the former ones, one on each side, and the spaces of ten or twelve feet will be marked out for the outside openings of the embrasures. In the direction of the pickets, which limit the inner and outer openings of the embrasures, let single rows of fascines be staked down across the wall, and these will be the sides of the embrasures: fill the intermediate spaces, or merlons, with rows or fascines laid lengthwise to the wall, and this will be the first floor of the merlon, which is to be picketted down, and the hollows filled with earth. Let other floors be raised in like manner, until the merlons are carried up to about five or six feet, or more if necessary; and on the top of each let a bed or floor of earth be laid of about eight or twelve inches thick.

MERLON, or *Mellon*, in *Geography*, a town of France, in the department of the Oise; seven miles S. of Clermont.

MERLUCIUS, *Gadus merluccius* of Linnæus, in *Ichthyology*, the name of a fish commonly called the *hake*, and by some authors the *asellus alter*.

It is a moderately large fish, growing to two feet or more in length, and resembling the common pike in figure, from whence it has its name, *merlucius*, *quasi maris lucius*, *the sea-pike*. See GADUS *Merluccius*.

MERMAID, or MERMAN, a sea-creature, frequently talked of, and supposed half human and half a fish.

However naturalists may doubt of the reality of *mermen*, or mermaids, if we might believe particular writers, there seems testimony enough to establish it. In the year 1187, as Larrey informs us, such a monster was fished up in the county of Suffolk, and kept by the governor for six months. It bore so near a conformity with man, that nothing seemed wanting to it besides speech. One day it took the opportunity of making its escape, and plunging into the sea, and was never more heard of. Hist. d'Angleterre, p. i, p. 403.

In the year 1430, we are told, that, after an huge tempest, which broke down the dykes in Holland, and made way for the sea into the meadows, &c. some girls, of the town of Edam, in West-Friesland, going in a boat to milk their cows,

cows, perceived a mermaid embarraffed in the mud with a very little water. They took it into their boat, and brought it with them to Edam, dreffed it in women's apparel, and taught it to fpin. It fed like one of them, but could never be brought to offer at fpeech. Some time after it was brought to Haerlem, where it lived for fome years, though ftill fhewing an inclination to the water. Parival relates that they had given it fome notions of a deity, and that it made its reverences very devoutly whenever it paffed by a crucifix. (Delices d'Hollande.) In the year 1560, near the ifland of Manar, on the weftern coaft of the ifland of Ceylon, fome fifhermen are faid to have brought up, at one draught of a net, feven mermen and maids; of which feveral Jefuits, and among the reft F. Hen. Henriques, and Dimas Bofquez, phyfician to the viceroy of Goa, are faid to have been witneffes. And it is added, that the phyfician, who examined them with a great deal of care, and made diffections thereof, afferted that all the parts, both internal and external, were found perfectly conformable to thofe of men. See the Hift. de la Compagne de Jefus, p. ii. tom. iv. N° 276, where the relation is given at length.

We have another account, as well attefted, of a merman, near the great rock called Diamond, on the coaft of Martinico. The perfons who faw it gave in a precife defcription of it before a notary: they affirmed, that they faw it wipe its hands over its face, and even heard it blow its nofe.

Another creature, of the fame fpecies, was caught in the Baltic, in the year 1531, and fent as a prefent to Sigifmund king of Poland, with whom it lived three days, and was feen by all the court. And another very young one was taken near Rocca de Sintra, as related by Damian Goes.

The king of Portugal, and the grand-mafter of the order of St. James, are faid to have had a fuit at law, to determine which party thefe monfters belonged to. See Sea-cow, and Siren. See Pontoppidan's Nat. Hift. of Norway, vol. ii. p. 186, &c.

MERMEREDGIK, in *Geography*, a town of Afiatic Turkey, in Natolia; 44 miles E. of Smyrna.

MERO, a diftrict of Teneffee, in America, on the banks of Cumberland river, comprehending feven counties and 32,178 inhabitants, of whom 8074 are flaves.

Mero *Point*, a point on the coaft of Peru, in the South Pacific ocean, between cape Blanco to the S.W., and Tumber river to the N.E., on the S.E. fide of Guayaquil bay. S. lat. 3° 40′.

Mero *Motu*. See Ex *Mero*.

MEROCELE, from μηρος, *the thigh*, and κηλη, *a tumour*, in *Surgery*, the crural or femoral rupture. See Hernia.

MEROLA, in *Geography*, a river of Naples, which runs into the Adriatic, N. lat. 42° 6′. E. long. 14° 55′.

MEROPE, a town of Peru, in the diocefe of Truxillo; 12 miles N.W. of Lambayeque.

MEROPS, the Bee-eater, in *Natural Hiftory*, a genus of birds of the order Picæ: bill curved, quadrangular, compreffed, carinate, pointed; noftrils fmall, at the bafe of the bill; tongue flender, the tip, generally, jagged; feet greffiorial. There are twenty-fix fpecies. The birds of this genus, with a few exceptions, inhabit the old continent. Their general food is infects, and they are particularly fond of bees and wafps. They have no note beyond a whiftle, and that far from an agreeable one. Like the king-fifher, they breed in holes in the banks of rivers.

Species.

* Apiaster. Back ferruginous; belly and tail blueifh-green; two of the tail-feathers longer; chin pale yellow. A variety occurs with the bill convex and uncarinated, and the toes unconnected at the laft joint. Bill black; irids red; front blue-green; crown, hind-head, and neck bay; a black ftreak from the bill to the hind-head; tail wedged, the feathers edged within with cinereous; legs chefnut; claws reddifh-black. This is one of the moft elegant of the European birds, and, next to the roller and king-fifher, may be regarded as the moft brilliant in point of colour. This bird is a native of the warmer parts of Europe, and of many parts both of Afia and Africa. It is rarely feen in the northern regions of Europe. In Greece, and among the iflands of the Archipelago, it feems to be extremely common, and we are told by Belon, that in the ifland of Crete the inhabitants practife a curious mode of catching it by means of a cicada, faftened on a bent pin, or a fifh hook, and tied to a long line; the infect is then thrown into the air, and flies with great rapidity, and the bee-eater, ever on the watch for infects, feeing the cicada, fprings at it, and fwallowing the bait, is thus taken by the Cretan boys. It has been feen in Sweden; and in the third volume of the Tranfactions of the Linnæan fociety, it is afferted that a flight of thefe birds, not lefs than twenty in number, was feen near Mattifhall in Norfolk, in the month of June 1793, and again in the following October. They feed, on the wing, upon bees, gnats, flies, and other infects. Their neft is compofed of mofs, and the eggs, from five to feven, are perfectly white, and about the fize of thofe of a ftare. When the fun fhines upon them, in their flight, they are a pleafing object, as they appear gilded. It is recorded by Kolben, the hiftorian of the Cape of Good Hope, that bee-eaters guide the Hottentots to the honey, which the bees lay up in clefts of the rocks.

Viridis, Indian Bee-eater. Green; band on the breaft black; chin and tail blue; two of the tail-feathers longer. It inhabits Bengal, and is eight or nine inches in length. Bill and band acrofs the eyes are black; legs are brown. There are four other varieties of this fpecies: in the *fecond*, the body is longer, front blue: in the *third*, the chin is yellow; line on the fides of the head black; quill-feathers tipt with brown. It is found in Egypt. The bill is black, ftraight; tongue not jagged; legs flefh-colour; tail even; in the *fourth* variety, the chin and ftripe beneath the eyes are blue; tail even; it is found in the Philippine iflands; two middle tail-feathers are black; in the *fifth* and laft variety, the front is of a pale yellow colour; chin blue, it inhabits India.

Congener, Yellow-headed Bee-eater. Yellowifh; rump greenifh; quill-feathers tipt with red; tail-feathers yellow at the bafe. Found in the fouthern parts of Europe. The band acrofs the eyes is black; back and fhoulders bay; leffer wing-coverts blueifh, the greater are yellow; quill-feathers black; legs yellow. According to Gefner it is often feen in the neighbourhood of Strafburg.

Superciliosus, Supercilious Bee-eater. Green, frontal line above and beneath the eyes white; chin yellowifh; two of the tail-feathers longer. There is a variety of this fpecies defcribed as having a flenderer bill; an even tail, with a rump and tail of blue-green. It inhabits Madagafcar, and is nearly a foot long. Bill and area of the eyes black; crown greenifh-bay; the legs are brown, and claws black.

Philippensis, Philippine Bee-eater. Green, beneath yellowifh; rump blue; tail even. This, as its name imports, inhabits the Philippine iflands, and is about eight or nine inches long. The bill and line through the eyes are black; legs and claws brown.

Cinereus, Cinereous Bee-eater. Variegated red and yellow, beneath reddifh-yellow; the two longeft tail-feathers are red. Inhabits New Spain, and is between nine and

and ten inches long. The bill is green; head, quill and lateral tail-feathers cinereous.

Flavicans, Yellow Bee-eater. Whitifh; head varied with white and tawny; breaft reddifh; back yellow; rump, wings, and tail rufous; two middle tail-feathers very long. In Willughby's Ornithology this fpecies is defcribed as the fecond bird of Paradife of Aldrovandus. This naturalift fays he obferved it, in the year 1577, in the poffeffion of a Roman knight of the name of Cavallieri. The head was nearly white, fprinkled with yellow, and gold-coloured fpots; the eyes were luteous, with red eye-lafhes; the bill between green and yellow, two fingers breadth long, and rather curved; the tongue red, longifh, and fharp, not unlike that of a wood-pecker, and calculated for piercing; the breaft reddifh; the back, wings, and belly whitifh, but the upper parts of the tips of the wings ferruginous; the upper part of the back yellowifh, but becoming reddifh or ferruginous at the rump; the tail-feathers were white at the bafe, but ferruginous for the remainder of their length, and the two middle feathers exceeded the others two palms in length. The wings in the figure of Aldrovandus appear very long in proportion to the bird, and the author fays they meafured five palms in length; the tail likewife, exclufively of the two middle feathers, appears of confiderable length.

Coromandus, Coromandel Bee-eater. Yellowifh; fides of the neck, wings, and tail yellow; wing-coverts, back, and rump waved blueifh, ocular ftripes black. Inhabits different parts of India and Coromandel, whence it derives its name. Bill and legs black; irids pale rufous; chin greenifh.

Brasiliensis, Brafilian Bee-eater. Varied brown and black; head, chin, leffer wing-coverts, and body beneath red; wings and tail blue. It is found, as its name imports, in Brafil; is about nine inches long; the bill, wings beneath, legs and claws yellow.

Superbus, Superb Bee-eater. Front and rump blue; two middle tail-feathers longer. Bill blackifh; quill-feathers edged with brown; lower half of the middle tail-feathers dark brown. The fize of this fplendid bird is nearly that of the common or European bee-eater.

Badius, Chefnut Bee-eater. Blue-green; head, neck, and fhoulders chefnut coloured; tail-feathers above blue, beneath grey-brown; two middle tail-feathers longer pointed. There is a variety that has the wings and tail chefnut. It inhabits the ifle of France. Bill black, band beneath the eyes brown; upper wing-coverts green, beneath tawny; quill-feathers beneath grey, four inner ones totally green; 13 middle ones tipt with black; tail-feathers grey at the inner edge; legs reddifh; claws blackifh.

Chrysocephalus, Yellow-throated Bee-eater. Green-gold, beneath blue-green; head and neck tawny; chin yellow; two middle tail-feathers longer. It is found in different parts of Afia, and is about ten inches long. The front and eye-brows blue-green; upper tail-coverts green.

Angolensis, Angola Bee-eater. Gloffy green-gold; band through the eyes cinereous, fpotted with black; wings and wedged tail beneath cinereous; chin yellow; throat chefnut. It inhabits, as its name expreffes, Angola, and is about five inches long. The bill and claws are black; legs cinereous; body beneath blueifh.

Erythrocephalus, Red-headed Bee-eater. Green, beneath yellowifh; head and neck red; chin yellow; wings and even tail beneath cinereous. It is found in India, and is about fix inches long. According to Briffon, the crown of the head and upper part of the neck are of a bright red; there is acrofs the eyes a black ftreak; all the upper parts of the bird are of a fine green; the throat and under parts yellow, but flightly dafhed, from the throat downwards, with red; tail even at the end, and rather fhort; irides red; bill black; legs brown.

Nubicus, Blue-headed Bee-eater. Blue-green, beneath red; back, wings, and forked tail dirty red. It inhabits Nubia, and is ten inches long. The bill is black; great quill-feathers tipt with blueifh-afh, the fecondary are blackifh; legs pale-afh.

Erythropterus, Red-winged Bee-eater. Olive, beneath whitifh, chin yellow; wings and tail red, tipt with black. It was defcribed by Buffon, from a fpecimen brought from Senegal by Adanfon. Its total length was about fix inches.

Cayanensis, Cayenne Bee-eater. Green; wings and tail rufous, the latter tipt with black. It is a native of Cayenne, from whence it derives its name. The bill is black; quill-feathers white at the bafe; the tail-feathers edged with black; legs yellowifh.

Surinamensis, Surinam Bee-eater. Variegated; hind-head reddifh; fcrag greenifh-yellow; quill-feathers greenifh, varied with black and blue. An inhabitant of Surinam. The irids are chefnut and claws black.

Novæ Seelandiæ, New Zealand Bee-eater. Gloffy greenifh-black; greater wing-coverts and tuft of curled feathers on each fide the neck white; tail even, coverts blue. Is found in New Zealand; is about 11 inches long; fings well; is held facred by the inhabitants; and the flefh is good. Legs and claws black; infide the mouth and tongue yellow, the latter tipt with black and befet with briftles; feathers of the neck lax, long, a little curled, with a longitudinal white ftreak through the fhaft.

Phrygius, Embroidered Bee-eater. Black variegated with yellow. This beautiful fpecies is the fize of a thrufh, and its black moft elegantly variegated with bright and pale yellow; the fides of the head, round the eyes, are covered by a naked, yellow, granulated fkin; the back and breaft undulated by numerous pale or whitifh-yellow crefcents, the tips of the black feathers being of that colour; the fmaller wing-coverts are marked in a fimilar manner; the larger tipt with bright yellow, and the quill-feathers edged with the fame colour, as are alfo the exterior tail-feathers; the bill is black, of a moderate length, and fharp-pointed; the legs are brown. It is a native of New Holland.

Niger, Yellow-tufted Bee-eater. Black; a large tuft of feathers behind the wings and vent yellow; tail wedged, edged and tipt with white. Native of the Sandwich iflands, where it is much efteemed on account of the tufts of yellow feathers beneath the wings, which are ufed in various ornamental articles of drefs among the natives, and on that account Dr. Shaw fays it might juftify us in placing this fpecies among a particular divifion of the genus Certhia. There are two other varieties, of which the *fecond* is known by having two middle tail-feathers uniform; and the *third* by its rufous flanks, and by its having all the tail-feathers uniform.

Carunculatus, New Holland Bee-eater. Brown, belly yellow; wattles carunculate; tail wedged, tipt with white. It inhabits New Holland, and is defcribed and figured in White's Voyage to New South Wales. It is fomewhat of the fize of a Miffel thrufh, but much longer in proportion, meafuring about fourteen inches. The feathers on the upper part of the head are longer than the reft, giving the appearance of a flight creft; the plumage of the bird is brown, the feathers long and pointed, and each feather has a white longitudinal ftreak; beneath the eye, on each fide the head, beyond the bafe of the lower mandible, is a lengthened pendent wattle of an orange colour; the

 middle

middle of the belly is yellow, the tail wedge-ſhaped, like that of the magpie, and the feathers are tipt with white. The bill and legs are brown. In ſome individuals of this ſpecies a ſilvery ſtreak appears beyond each ſide of the bill, and in the young birds the white ſtreaks on the plumage terminate in a kind of dilated ſpot at the tip of each feather.

Corniculatus, Horned Bee-eater. Brown, head nakedifh; body beneath and tips of the tail-feathers whitiſh; horn on the front obtuſe. This is alſo an inhabitant of New Holland, and is deſcribed and figured by Mr. White. It is rather larger than a black-bird, the plumage above is brown, and beneath it is white; the head and upper part of the neck is ſparingly covered with narrow white feathers, almoſt like hairs; but the fore-part of the neck and breaſt are furniſhed with long ones of a white colour with a dark middle ſtreak, and pointed at the ends; its moſt remarkable feature is, that on the forehead, juſt at the baſe of the bill, there is a ſhort blunt knob, about a quarter of an inch in height, and of a browniſh colour; the tongue is nearly the length of the bill, and briſtly at the end; the legs are dark brown.

Gularis, Red-throated Bee-eater, and ſometimes, from its colour, called the Black Bee-eater. Black; forehead and rump blue; belly ſpotted with blue; throat red. It inhabits Sierra Leona. In ſize it is rather ſmaller than the common bee-eater, and its prevailing colour is the fineſt velvet black; the forehead is of the richeſt blue, ſo alſo is the rump, ſurpaſſing that of the king-fiſher; the throat is of a bright blood-red, the larger wing-coverts and middle quill-feathers bordered with bright ferruginous; the tail is even at the end; the bill and legs black.

Rufus, Rufous Bee-eater. Quill-feathers brown, the outer edge rufous. Body beneath inclining to yellow; toes ſeparated to the baſe; hind-claw longer. It is obſerved by Buffon, that as the toes in this ſpecies are not united, as in the reſt of the genus, it ſeems to form as it were a connecting link, or ſhade, between the bee-eaters and the hoopoes.

Moluccensis, Molucca Bee-eater. Grey; orbits naked; cheeks black; tail ſubequal. It is a native of the Molucca iſlands, and is about 14 inches long. The bill is blackiſh, pervious, half covered with a membrane; tongue as long as the bill, fringed at the tip; ſome of the feathers of the cheeks are tipt with a ſilvery colour; legs duſky; outer toe connected with the middle one; hind-claw longer.

Monachus, Brown or Cowled Bee-eater. Deſcribed by Latham, white beneath, with black and ſomewhat downy head with raiſed crown. It is a large ſpecies, and a native of New Holland.

Malimbicus, Malimba Bee-eater. Sanguine roſe coloured beneath, with black eye-ſtripe, white throat, and two lengthened tail-feathers. This is a native of Malimba, in Congo, Africa, where it continues only three months in the year; migrating in troops, flying with the ſwiftneſs of a ſwallow, feeding on inſects, rarely perching on trees; nor on the ground any length of time.

MEROS, in *Ichthyology*, the name of a very large American fiſh, growing to five or ſix feet long, and called by the Braſilians *cugupu-guacu*. Its head is very large, and its mouth wide and toothleſs; its eyes have a black pupil and a yellow iris; it hath five fins, one running the whole length of the back and reaching nearly to the tail; the anterior part of this is narrow, and armed with ſmall but ſharp ſpines; the other part is broader, and ſuſtained by ſofter rays; behind the anus is one like the hinder part of that on the back, and two others behind the gills, which are large and broad; the tail fin is very large and broad, and much more ſo at its extremity than at its origin; the ſcales are ſmall; the head, back, and ſides are of a browniſh-grey; and its belly white. It is accounted a well taſted fiſh. Ray. See Perca *Guttata*.

MEROSAGLIA, in *Geography*, a town of the iſland of Corſica; 14 miles N.E. of Corte.

MEROVEUS, in *Biography*, king of France, or of the Franks, whoſe monarchy, at that time, was confined to both banks of the Lower Rhine, began his reign about the year 448. Little is known of his origin and deſcent, but the moſt probable opinion ſeems to be, that he was the younger of the two ſons of Clodion, his predeceſſor, and that he obtained the crown of the Franks through the protection of Valentinian III., and his miniſter Aëtius. Attila ſupported the cauſe of his elder brother, and Meroveus was preſent as an ally of the Romans in the famous battle of Chalons, fought againſt that conqueror in 451. He afterwards probably extended his dominion in the provinces of Mentz and Rheims, to the banks of the Seine, and it has been ſaid, that in conſequence of his celebrity and renown, all the French kings of the firſt race bore the name of *Merovingian*, though others maintain that the appellation is older than this ſovereign. He died about the year 456. Gibbon. Univer. Hiſt.

MEROVINGIAN Character, derives its name from Meroüée, the firſt king of France of that race, which reigned 333 years, from Pharamond to Charles Martel. This race is ſaid by ſome to have terminated in Childeric III. A.D. 751. There are many MSS. in the French libraries ſtill extant in this character. See Spect. de la Nat. vol. vii. p. 190.

MERRET, Christopher, in *Biography*, a phyſician and naturaliſt, was born at Winchcombe, in Glouceſterſhire, in February 1614. He was educated at Oxford, being firſt entered at Glouceſter hall, and ſubſequently removing to Oriel, and took the degree of M.D. in 1642, when he ſettled in London. He appears to have enjoyed a conſiderable ſhare of practice in his profeſſion, was a fellow of the College of Phyſicians, and one of the original members of the Philoſophical Society, which after the reſtoration became the Royal Society. He died in 1695. Merret was a ſtrenuous ſupporter of the excluſive rights of the college, and his firſt publication was "A Collection of Acts of Parliament, Charters, Trials at Law, and Judges' Opinions, concerning thoſe Grants to the College of Phyſicians," 4to. 1660. This book became the baſis of Dr. Goodall's Hiſtory of the College, and it was followed, in 1669, by "A ſhort View of the Frauds and Abuſes committed by Apothecaries, in relation to Patients and Phyſicians." This publication involved him in an angry controverſy with Henry Stubbe. He was known to the public, however, more reputably as a naturaliſt, by the publication of his work, entitled "Pinax Rerum Naturalium Britannicarum, continens Vegetabilia, Animalia, et Foſſilia in hac Inſula reperta," Lond. 1667, 8vo. This, though a dry and incomplete catalogue, and abounding with errors, has the merit of being the firſt of the kind relating to this country, and was without doubt inſtrumental in promoting the ſtudy of natural hiſtory here. The botanical part is the fulleſt, conſiſting chiefly, however, of an alphabetical liſt, according to the Latin names. A great portion of his knowledge of plants was obtained through the medium of Thomas Williſel, a noted herbaliſt, whom he employed to travel through the kingdom for him during five ſummers. The zoological and mineral parts of his pinax are very meagre. Merret communicated ſeveral papers to the Royal Society, which are printed in the earlier volumes of the Philoſophical Tranſactions; particularly an account of ſome experiments on vegetation; of the tin mines in Cornwall; of the art of refining; and ſome curious obſervations relative to the fens of Lincolnfhire. In 1662, he tranflated into Englifh, Neri's work "De Arte Vitraria." In 1686, an edition of the fame work was publifhed in Latin, with Merret's obfervations and notes; and fubfequently a work was printed in German and French, comprehending all that had been written by Neri, Merret, and Kunckel, upon this art. Eloy Dict. Hift. Gen. Biog.

MERRIMACK, in *Geography*, a river of America, which is formed by the confluence of Pemigewaffet and Winnipifcogee rivers in about N. lat. 43° 26′, and which purfues a foutherly courfe through the ftate of New Hampfhire, till it enters Maffachufetts, and then turning eafterly, paffes into the ocean at Newbury-Port. It is navigable for veffels of burden about 20 miles from its mouth.

Merrimack, a townfhip in Hillfborough county, New Hampfhire, on the W. bank of Merrimack river; eight or ten miles S. of Amherft; containing 926 inhabitants.

MERRIMICHI, a river of America, which falls into the head of a bay of that name on the N.E. coaft of the province of New Brunfwick. From this river there is a communication with St. John's, partly by land, but principally by water carriage in canoes. The falmon fifhery is carried on with fuccefs, and the cod-fifhery is improving near the entrance of the bay.

MERRITCH, or Merrick, a town of Hindooftan, in the country of Vifiapour, fituated on the N. fide of the Kiftnah; 50 miles S.W. of Vifiapour. N. lat. 16° 58′. E. long. 74° 47′.

MERRY, Robert, in *Biography*, was born in London, April 1755, and was defcended in a right line from fir Henry Merry, who was knighted by James I. at Whitehall. Mr. Merry's father was governor of the Hudfon's Bay Company. His grandfather was a captain in the royal navy, and one of the elder brethren of the Trinity Houfe; he eftablifhed the commerce of the Hudfon's Bay Company upon the plan which it now purfues. He made a voyage himfelf to Hudfon's Bay, and difcovered the ifland in the North feas, which ftill bears the name of Merry's ifland. He alfo made a voyage to the Eaft Indies, and was, perhaps, the firft Englifhman who returned home over land; in which expedition he encountered inconceivable hardfhips. Mr. Merry's mother was the eldeft daughter of the late lord chief juftice Willes, who prefided for many years with great ability in the court of Common Pleas, and was for fome time firft lord commiffioner of the great feal. Mr. Merry was educated at Harrow, under Dr. Sumner. The celebrated Dr. Parr was his private tutor. From Harrow he went to Cambridge, and was entered of Chrift's college. He left Cambridge without taking any degree, and was afterwards entered of Lincoln's Inn, but was never called to the bar. Upon the death of his father he bought a commiffion in the horfe-guards, and was for feveral years adjutant and lieutenant to the firft troop, commanded by lord Lothian. Mr. Merry quitted the fervice and went abroad, where he remained nearly eight years; during which time he vifited moft of the principal towns of France, Switzerland, Italy, Germany, and Holland. At Florence he ftayed a confiderable time, enamoured (as it is faid) of a lady of diftinguifhed rank and beauty. Here he ftudied the Italian language, encouraged his favourite purfuit, poetry, and was elected a member of the academy Della Crufca; the name of which academy he afterwards ufed as a fignature to many poems which were favourably received by the public, and which excited a great number of imitators. When Mr. Merry obferved this, he dropped his fictitious character, and ever afterwards publifhed in his own name.

Upon his marriage with Mifs Brunton, who performed in his tragedy of Lorenzo, a profpect opened to him of living at his eafe, by the joint production of that lady's talents, and his own pen; but unfortunately the pride of thofe relations upon whom he had moft dependence was wounded by the alliance; and he was conftrained, much againft Mrs. Merry's inclination, to take her from the ftage. This he did as foon as her engagement at the theatre expired, which was in the fpring of 1792. They then vifited the continent, and returned in the fummer of 1793. They retired to America in 1796, and our author died fuddenly at Baltimore, in Maryland, Dec. 24, 1798, of an apoplectic diforder, which proceeded, as is fuppofed, from a plethora, and the want of proper exercife. He was author of the following dramatic pieces, *viz.* "Ambitious Vengeance;" "Lorenzo;" "The Magician no Conjurer;" and "Fenelon," a ferious drama. Monthly Magazine, Jan. 1799.

Merry's *Ifland*, in *Geography*, an ifland in Hudfon's Bay. N. lat. 61° 52′. W. long. 93° 5′.

MERRY-MEETING Bay, a bay of America, in Strafford county, New Hampfhire, being the fouthernmoft arm of lake Winnipifcogee. On its W. fide ftands mount Major. —Alfo, a bay in Maine, formed by the junction of Androfcoggin and Kennebeck rivers, oppofite to the town of Woolwich, 20 miles from the fea.

MERS Agoleta, a town of Algiers, near the fea-coaft; fix miles S.W. of Tneifs.

Mers *il Keeber*. See Mazalquivir.

MERSA, El, a town of Africa; 12 miles N.E. of Tunis.

MERSBURG, or Morspurg, a town of the duchy of Baden, feated on the lake of Conftance, containing a feminary for fecular clergy, and a nunnery of the Dominicans; fix miles N.E. of Conftance. N. lat. 47° 41′. E. long. 9° 14′.

MERSCH, a town of France, in the department of the Forefts, and chief place of a canton, in the diftrict of Luxembourg. The place contains 1446, and the canton 8185 inhabitants, on a territory of 217½ kiliometres, in 15 communes.

MERSCHOWITZ, a town of Bohemia, in the circle of Leitmeritz; 14 miles W.S.W. of Leitmeritz.

MERSEA, a townfhip of Upper Canada, in the county of Effex, feated on lake Erie, W. of Romney.

MERSEBURG, a principality of Saxony, encompaffed by the circles of Leipfic and Thuringia, the principality of Querfurt, and duchy of Magdeburg. The foil is fertile, and well cultivated, producing wheat, millet, and flax, but wanting wood.—Alfo, the capital of the above-named principality, feated on the Saale. It contains within the liberties of the Chapter, the epifcopal palace and cathedral; a gymnafium or foundation fchool, the chancery-houfe, the chapter-houfe, the curiæ or refidences of the canons, and other buildings. It has alfo a parifh church; and derives its chief fubfiftence from the ftrong beer that is brewed here and exported to different places; 16 miles W. of Leipfic. N. lat. 51° 22′. E. long. 14° 6′.

MERSENETI, a town of Afiatic Turkey, in Natolia; 10 miles S.E. of Milets.

MERSENNE, Marin, in *Biography*, a learned French mathematician and philofopher, was born at Oyfe, in the province of Maine, in the year 1588. He purfued his college ftudies at La Fleche, where he had as a fellow ftudent the celebrated Des Cartes, with whom he contracted an intimacy and friendfhip that lafted during their lives. Here Merfenne rendered himfelf confpicuous for the diligence and rapid progrefs which he made in his various ftudies. From La Fleche he went to the univerfity of Paris, where he paid the

the utmost attention to the mathematical sciences; after which, he went through a theological course at the Sorbonne. When he had completed his studies, he entered himself at the convent of Minims near Paris, and took the vows in 1612, when he was only 24 years of age. In the following year he was ordained priest, and began to study the Hebrew language, of which he made himself a complete master. In 1615 he was sent to the convent of his order near Nevers, to fill the philosophical chair in that house; and he continued there, teaching philosophy, and afterwards theology, till the year 1619, when he was chosen superior of the convent. Upon the expiration of the term of his office, which was annual, he withdrew to Paris, where he spent the remainder of his life in study and literary converse, excepting such time as he devoted to short excursions into Italy, Germany, and the Netherlands. While at this great city, he was the chief friend and literary agent of Des Cartes, giving him advice and assistance upon all occasions, and informing him of every thing of a literary and philosophical kind that was going on in that city, and elsewhere. So highly did Des Cartes estimate the opinion of our philosopher, that he scarcely did any thing, without first consulting his friend. It has been reported, that when Des Cartes was about to found his system of philosophy upon the principle of a vacuum, he was informed by Mersenne, who had founded the Parisian philosophers upon it, that it would not be admitted, and immediately changed his system, and adopted the opposite doctrine of a plenum. Mersenne was much celebrated for possessing the peculiar talent of forming curious questions and problems; some of which, it afterwards appeared, he was unable to solve. To him has been ascribed the invention of the curve, well known by the name of the "cycloid," which instantly engaged the attention of mathematicians. Schooten, indeed, ascribes the invention to Des Cartes; but Torricelli, in the appendix, "De Dimensione Cycloidis," says, the curve was discovered and named by Galileo and others, about the year 1599, before Mersenne and Des Cartes could have made much progress in mathematical learning. Dr. Wallis, in the first volume of the London "Philosophical Transactions abridged," attempts to shew that it is a much older invention, and was known to Bovilli in the year 1500, and by cardinal Cusa a full half century before this. Mersenne died in the year 1648. The loss of him was deeply regretted by persons of all ranks who were acquainted with him, by whom he was as much beloved for the cheerful qualities of his heart, and his mild and amiable temper, as he was respected for his profound scientific knowledge. He was, while a resident at Paris, the very centre of communication between literary men of all countries; being there, what Mr. Collins was in England. He omitted no opportunity of engaging them to publish their works; and to Mersenne the world is indebted for several important discoveries, which would probably have been lost, but for his encouragement and patronage. His own works were numerous, and many of them highly important. The first which he published, of any magnitude, was entitled "Quæstiones celeberrimæ in Genesim, &c. cum accurata Textus Explicatione. In hoc Volumine Athei et Deistæ impugnantur et expugnantur." The other works of this philosopher are enumerated in the General Biography, to which our readers are referred.

In the musical writings of this diligent and ingenious ecclesiastic may be found the most minute and satisfactory account of the state of music in France, during the reign of Louis XIII., particularly in his "Harmonie Universelle," published at Paris in 1636, in folio; a work in which, through all the partiality to his country, want of taste, and method, there are so many curious researches and ingenious and philosophical experiments, which have been of the greatest use to subsequent writers, particularly Kircher, as render the book extremely valuable. This work, corrected and enlarged, was translated into Latin, and published by the author in 1648, the year of his death, under the following title, "De Sonorum Natura, Causis et Effectibus." In his twenty-third proposition, liv. i., this author explains and describes twelve different kinds of music and movement, used in France during his time: these were motets, songs or airs, passacailles, pavans, allemandes, gaillards, voltes, courantes, sarabandes, canaries, branles, and balets; of all which he gives examples in notes. But though most of these movements were the specific names of the dances then in vogue, the minuet, which, during the present century, has been in such general favour all over Europe, is never mentioned.

In the "Pref. generale," Mersenne speaks of Galileo's discoveries in harmonics; and in his liv. ii. "Des Consonances," of sympathic vibrations. In other parts of his work he explains clearly the twelve keys major of practical music; and shews, for the first time perhaps, that there may be seventy-two keys, or six for each note, flat, natural, and sharp, major and minor. There is nothing in this good father's book which reflects more honour on his taste and penetration than his partiality for the violin, to which, in liv. iv, "Des Instrumens," prop. i. he gives the preference over all other instruments then in use, at a time when it was thought unworthy of being admitted into the concerts of other countries.

It is amusing, however, to see how contented mankind have ever been, in the most rude and uncultivated ages of the world, with their own talents and accomplishments. A singular instance of this mental comfort appears in Mersenne, chap. "De l'Embellissemens des Chants," which he addresses "to posterity, that they may form some idea," says he, "of our manner of gracing and embellishing airs; as such advances have at no time been made in polishing and refining melody, as at present." In his treatise "De la Voix," where he explains the manner of running divisions and making shakes, he says, that "of all nations who study singing, and who run divisions in the throat, the French execute passages in the neatest manner: this even the Italians confess, who make a particular profession of singing. It is impossible," adds he, "to describe the beauty and sweetness of our vocal embellishments to such as have not heard them; for the purling of a stream, the meandering of a brook, or the warbling of a nightingale, is not half so mellifluous. And I find nothing in nature," continues this pious father, "that can give the least idea of these passages, which are far more ravishing than shakes or trills, for they are the very quintessence of music." (Liv. i. De la Voix, p. 40.) He afterwards observes, that no traces are to be found in the writers of music among the ancient Greeks, that this ingenious and voluptuous people ever had "des fredons & des passages comme nous autres:" trills and divisions in their music, like us.

One proposition in this book (xxxiv.) is to inquire whether the French method of singing is the best of all possible methods? and determines in the affirmative, not only with respect to this proposition, but affirms that of all those he had heard sing in neighbouring countries, as in Spain, Germany, Flanders, and Italy, he had met with none who sung so agreeably as the French. "There may," says he, "be now and then a miraculous performer in other countries, but I speak here in general."

He mentions recitative as a thing little practised in France, for

for want of courage. The Italians, he obferves, had fucceeded in this fpecies of finging, which Giacomo Peri had invented at Florence the beginning of the century. Here he fpeaks of feveral mufical dramas in Italy, but does not call them operas. (Liv. vi. L'Art de bien Chanter.) A book with the fame title was publifhed at Paris, by Bacilly, 1668.

The *fi*, to exprefs the feventh of the key, does not feem to have been in ufe at this time in France; as Merfennus in his folmifation has never introduced it, repeating the *mi*, in the key of C, for E and B.

MERSEY, in *Geography*, a navigable river of England, flows from the eaft to the weft, and forms, in the greater part of its courfe, a natural boundary between the counties of Lancafter and Chefter. Its whole extent is about fifty miles; thirty-five of which are navigable, from Liverpool to the mouth of the river Irwell, for veffels of confiderable burthen. The Merfey derives its origin from the junction of the rivers Etherow and Goyt, where it affumes the prefent name, and in its courfe receives the ftreams of the Tame, the Bollen, the Irwell, and the Weever. Oppofite Warrington in Lancafhire, where it meets the tide-water, the Merfey is only forty yards wide; but at Runcorn-gap, where it communicates with the Grand-trunk, and duke of Bridgewater's canals, its width is three hundred yards: below the gap, it extends itfelf into a grand eftuary of three miles in width, and receives the navigable river Weever from Northwich and Frodfham. In its courfe northward from Runcorn, it gradually diminifhes for fix miles, and oppofite Liverpool is only three-quarters of a mile wide; but it forms a fine channel, at leaft ten fathoms deep at low water, and is very commodious for fhipping. About five miles farther, meafuring by the Chefhire coaft, it falls into the Irifh fea, by two or three different channels, which are much incommoded by fands; but the paffage is rendered fecure by means of various land-marks, buoys, and light-houfes, and the excellent fyftem of pilotage eftablifhed by the Liverpool merchants. Lyfons's Magna Britannia, vol. ii.

MERSIG, a town of France, in the department of the Sarre, and chief place of a canton, in the diftrict of Sarrebruck. The place contains 1832, and the canton 6421 inhabitants, in 20 communes.

MERTAQUE, a town of New Spain, in the province of Honduras, which produces cochineal.

MERTENSIA, in *Botany*, a genus of the Submerfed *Algæ*, commonly termed Sea-weeds, named by the celebrated Thunberg, in honour of Profeffor F. C. Mertens, of Bremen, a man of the moft amiable character, highly diftinguifhed by his knowledge of this tribe of vegetables in particular. A treatife illuftrating this genus was publifhed by Dr. Roth, in Schrader's New Journal for 1807. A *Mertenfia* had indeed previoufly appeared, from the pen of Profeffor Willdenow, in the Stockholm Tranfactions for 1804, belonging to the order of Ferns; but that being reduced to another genus, (fee GLEICHENIA,) the prefent is eftablifhed; and as far as any opinion can be formed of fo unfettled a tribe, it feems to be tolerably diftinct from all that have already been adopted. Roth. in Schrad. New Journ. v. 2. fafc. 1. 11. t. 1. f. B.—Clafs and order, *Cryptogamia Algæ*. Nat. Ord. *Algæ*, Linn. Juff.

Eff. Ch. Frond internally jointed. Seeds difperfed in the coats of cluftered inflated vefícles.

1. M. *lumbricalis*. Roth as above. (Ulva lumbricalis; Linn. Mant. 311. Syft. Veg. ed. 14. 972. Thunb. Prod. 180.)—Gathered by Koenig, as well as by Thunberg, upon fubmarine rocks at the Cape of Good Hope. The *root* confifts of many flender entangled fibres, attaching themfelves to fhells and ftones. *Fronds* feveral, three or four inches high, cylindrical, bluntifh, tapering at the bafe, determinately branched, the thicknefs of a crow's quill, or more, greenifh-yellow, or purplifh, compofed of a thickifh coriaceous coat; internally fpongy, and interrupted by very frequent tranfverfe reticulated partitions, which are fcarcely difcoverable at the outfide. *Fructification* generally axillary, rarely lateral, confifting of numerous crowded, obovate, or oblong, vefícles, proceeding from a flightly elevated flefhy bafe, or *receptacle*. Each of thefe is jointed internally like the frond, but their coat is rather thinner and more pellucid, lodging very numerous, fcattered, roundifh-oval, cryftalline *feeds*. The fpecimens in the herbarium of Linnæus juftify his defcription of the fructification being terminal, but Roth afferts that it becomes fo only by accidental injuries to the frond. The internal partitions are confidered by this great cryptogamift of a fpurious nature, as originating from cellular fubftance only, which dilates into a tranfverfe web or net. The *feeds* are difperfed under the external cuticle, exactly as in real *Ulvæ*, though confined to the above-mentioned veficular excrefcences, which however feem materially different from branches, nor do they appear ever to be extended into fuch.

MERTHYR TYDVIL, or *Tudfyl*, in *Geography*, a large and populous market-town, fituated in the cwmwd of Senghenydd, cantref of Brenhinol, now the hundred of Caerphilly, and county of Glamorgan, South Wales. It is a place of great antiquity, and is faid to derive its name from Tydvil, the daughter of Brechan, prince of Brecknockfhire, who was murdered here, along with her father and brother, Rhun Dremrudd, by a party of Saxon marauders, about the clofe of the fifth century. Tydvil was the wife of Cyngin, fon of Cadell, prince of the vale royal and part of Powys, and is reckoned among the number of the ancient Britifh faints. After her death, the Saxons having been expelled by the prowefs of her nephew, Nevydd, a church was erected and dedicated to her at this place, and called the church of Merthyr Tydvil, which in Welfh fignifies "the Martyr Tydvil."

From this period, nothing occurs deferving of notice relative to Merthyr Tydvil, till about the year 1620, when it was diftinguifhed for its zeal in the caufe of non-conformity. Though then trivial in extent and political importance, it was neverthelefs a fort of hot-bed, which contributed in no fmall degree to engender and keep alive, for more than a century, thofe religious diffentions, the effects of which ftill continue vifible in the feparation of the greater proportion of the inhabitants of Wales from the eftablifhed church. In 1755 a new era commenced in the hiftory of this place. The extenfive and valuable mines in its immediate vicinity had hitherto attracted but little notice. At this time, however, Mr. Bacon particularly directed his attention towards them; and having obtained a leafe of a diftrict, extending about eight miles in length, and four in breadth, at the moderate rent of 200*l.* *per annum*, immediately began operations, and erected extenfive works for the fmelting and forging of iron. This gentleman continued increafing his eftablifhment till the year 1783, when he deemed it proper to let out the greater part of his property to Mr. Crawfhay, and the remainder to Mr. Hill: at the fame time, he referved to himfelf a certain tonnage on all the iron manufactured above a fpecified quantity. The new proprietors foon augmented the works; and the part belonging to Mr. Crawfhay, at Cyfartha, are now by far the largeft in this kingdom, and probably in Europe. He employs no fewer than 1500 men, at an average of 30 fhillings a week *per* man. The weekly wages paid for labour amount to 1500 pounds.

The

The average of iron produced from these works is from 180 to 200 tons a week. Six furnaces and two rolling-mills are employed. For procuring blast for the furnaces and working the mills, there are four steam-engines; one of fifty, one of forty, one of twelve, and one of seven horse power. The first engine is connected with the four upper blast-furnaces, to which is a water-engine annexed of nearly the same power. The machinery of this establishment is truly gigantic; and that part of it worked by water is curious, and certainly highly powerful. The great water-wheel is a most extraordinary piece of mechanism: it was constructed under the superintendance of Watkin George, and measures 50 feet in diameter. W. George was then a carpenter employed about the works: he was afterwards taken into partnership, and received 20,000*l*. to give up his share. Besides these works, and those of Mr. Hill, there are two others at Pendarren and Dowlais; the former producing about 140 tons of iron weekly, and the latter about three fourth-parts of that quantity. The total number of smelting-furnaces near this town is seventeen, *viz.* Dowlais four, Pendarren three, Plymouth (Mr. Hill) four, and Cyfartha six.

No fact can better illustrate the magic influence of trade on the condition of a country, than the rapid change which has been effected at Merthyr Tydvil and its neighbourhood. Forty years ago, this town was an inconsiderable village, and contained only a few hundred inhabitants; whereas, by the sole operation of its iron-works, it has risen to be by far the largest and most populous town in Wales. The inhabitants of this parish were estimated at 7705, in 1801; but the population is conjectured to amount to 10,000 persons. In 1803 the money raised for the poor rates, at 6*s*. 6*d*. in the pound, was 1453*l*. 17*s*. 10½*d*. The streets in general are close and confined, and have no proper outlets behind the houses. Considerable improvements, however, have already been made within these last five or six years. Such streets as have been built since that period are much better arranged, and wider than those which were erected earlier. At Pendarren is a large and elegant house, surrounded by beautiful gardens and pleasure-grounds, belonging to Mr. Homfray. The parish church, rebuilt in 1806, is a large and handsome building; and besides it, there is a spacious chapel built by Mr. Crawshay. The meeting-houses for dissenters of different sects are about eleven in number: three Baptists, two Presbyterian, two Independents, two in the Wesley connection, and two in that of Whitfield. A theatre has been lately erected here. There is likewise a philosophical society here, as well as a printing-house, and a book-seller. The inhabitants of this town are chiefly Welsh, and the language spoken in it almost entirely so. Less immorality prevails than might be expected in a place where the population consists chiefly of the lower orders. This is partly owing to the circumstance of the iron-masters and clergymen being usually magistrates for the county, and partly to the effect of religious instruction. These magistrates have the power of nominating the requisite number of constables, and must submit all their proceedings to the quarter and great sessions. A court of conscience, for the recovery of small debts, has been instituted here by act of parliament, within these three years. This town has three market-places, which are well supplied twice every week, on Wednesdays and Saturdays. It has likewise several fairs during the year.

The weighty and valuable productions of Merthyr Tydvil find an easy conveyance to the sea, by means of a canal which extends hence to Penarth harbour, in the Bristol channel, being navigable as far as Cardiff for vessels of 300 tons, and above that town for barges of 100 tons. This canal, begun about 22 years ago, was completed in 1798. At the Cyfartha works, where it terminates, it is 568 feet above the level of the sea; which elevation is effected by means of about 40 locks. A new tram road runs nearly by its side, through its whole course, extending altogether 26 miles in length.

Besides its iron ores, the neighbourhood of this town is abundantly productive of other minerals useful in the arts, and consequently subservient to the convenience and happiness of man. Coal, so indispensibly necessary in the manufacture of the iron, is supplied in immense quantities, and of excellent quality. Good mill-stones and stones for paving are likewise abundant; and in the lime-stone rocks are found beds of black and variegated marble, not inferior to any in the kingdom.

About two miles from the town, on the summit of a lofty mountain, is situated a very ancient market-place, where weekly markets have now been held for upwards of 800 years, during the summer season, from the 14th of May till the 14th October. This singular market is still much frequented. Several fairs are likewise held here for cattle, though the houses in the place do not exceed six in number.

Morlais castle stands about three miles to the north-west. It is situated on the summit of a hill, about half a mile from the ancient road over the mountains from Cardiff to Brecknock, overlooking a ravine of great depth, in the bottom of which runs a branch of Taff Vechan river. The area of this castle forms an irregular pentagon, defended on the south and east sides by a very large and deep trench cut in the solid rock. On the north and west sides it is rendered sufficiently strong, by the bold and rugged precipices which overhang the dingle. The whole of this castle is now in ruins. It was built by Ivor Petit, or Ivor Bach, the son of Cedevor, who was no less distinguished for his valour than for the uncommon smallness of his stature. Malkin's Scenery, Antiquities, and Biography of South Wales, 2 vols. 8vo. 1807. Carlisle's Topographical Dictionary of Wales, 1 vol. 4to. 1811.

MERTOLA, a town of Portugal, in Alentejo, seated on the Guadiana, containing about 2400 inhabitants; 24 miles S.S.E. of Beja. N. lat. 37° 36′. W. long. 7° 37′.

MERTON, a village in the west half-hundred of Brixton, in the county of Surrey, England, is situated on the Epsom road, nine miles distant from London. It contained in the year 1801, according to the return then made to parliament, 151 houses, occupied by 813 persons. The manor, which before the Conquest was the property of earl Harold, and was afterwards held by the crown, was granted by Henry I. to Gilbert Norman, sheriff of Surrey, who, in the year 1115, built a convent for canons regular of the order of St. Austin. The establishment was patronised by the king and his queen Matilda. In 1130, Merton abbey, as it was then called, was built with stone; and in 1136 the canons entered on the possession of it. The benefactions to it were numerous and ample. In the year 1236 a parliament was held at the abbey, wherein were enacted the statutes which take their name from that place. In this house also was concluded the peace between Henry III. and the dauphin of France. The abbey was surrendered in 1538; and the scite was afterwards granted to the newly-established monastery at Shene. After the dissolution, it was leased out to private persons; and during the civil war of Charles I. it appears to have been used as a garrison. At present there is no other vestige of the abbey than the east window of a chapel of crumbling stone, which seems, from its style, to have been built in the fifteenth century. The walls which surround the premises, including a space of about 60 acres, are

are nearly entire. The scite has long been occupied by two extensive manufactories for printing calicoes; and a copper mill is also established here.

The parish church of Merton was built, early in the twelfth century, by Gilbert Norman, the founder of the abbey. It is constructed of flints, and consists of a nave and chancel; and at the west end is a low spire. From the style of architecture, it is presumed to be the original structure, which has undergone but little alteration. In the chancel window are some remains of painted glass; and against the north wall of the church is a large picture of Christ bearing the cross.

Merton-Place, the seat of the late admiral Nelson, is in this parish; as is Cannon-hill, the villa of William Mollesson, esq. Sir Richard Hotham had a seat here, which was purchased by —— Graves, esq. Lysons's Environs of London, vol. i.

MERTVOI Kultuck, a bay at the north extremity of the Caspian sea. N. lat. 46°.

MERTZA, a small island in the north part of the gulf of Bothnia. N. lat. 65° 27'. E. long. 22° 9'.

MERTZBACH, a town of the duchy of Wurzburg; 6 miles N.N.E. of Ebern.

MERU, a town of France, in the department of the Oise, and chief place of a canton, in the district of Beauvais; 12 miles S.S.E. of Beauvais. The place contains 1800, and the canton 7131 inhabitants, on a territory of 165 kiliometres, in 20 communes.

Meru, a very celebrated mountain, in the mythological fables of the Hindoos. The word in Sanscrit signifies an *axis*, or *centre*; and hence, perhaps, it has been applied to the north pole, which, being deemed the most elevated region, led the poets to describe Meru as the highest mountain in the world. It is also, by way of pre-eminence, called Sū-merū, denoting its fairness or beauty. In the 15th chapter of the first book of the Mahabarat, it is thus described: "There is a fair and stately mountain, and its name is Mĕroo; a most exalted mass of glory, reflecting the sunny rays from the splendid surface of its gilded horns. It is clothed in gold, and is the respected haunt of dews and gandharvas (deities and celestial choristers). It is inconceivable, and not to be encompassed by sinful man; and it is guarded by dreadful serpents. Many celestial medicinal plants adorn its sides; and it stands, piercing the heavens with its aspiring summit, a mighty hill, inaccessible even by the human mind. It is adorned with trees and pleasant streams, and resoundeth with the delightful songs of various birds." (Gita, p. 146.) The above is the introduction to the story of the Kurmavatara, given by the learned translator in a note on the Gita. (See Kurmavatara and Brachmans.) This may be deemed sufficiently extravagant; but it is tame, compared with some of the ravings of Hindoo mystics, who find, in the contemplation of this mysterious mountain, types and symbols of every thing in and out of nature. Here follows a specimen of the Brahmanda Purana, taken from Mr. Wilford's dissertation on the Sacred Isles in the West, in vol. viii. of the Asiatic Researches. "Meru is the sacred and primeval Linga, and the earth beneath is the mysterious Yoni, open like the Padma or Lotos. The convexity in the centre is the Os tincæ, or navel of Vishnu: and the Hindoos often represent the physiological mysteries of their religion by the emblem of the Lotos, where the whole flower signifies both the earth and the two principles of fecundation; the germ is both Meru and the Linga; the petal and filaments are the mountains which encircle Meru, and are also the type of the Yoni; the four leaves of the calyx are the four vast regions towards the cardinal points; and the leaves of the plant are the different islands in the ocean round Jambu." At the end of this ingenious essay are curious plates, representing Meru under the fanciful semblance of a lotos, and other geographical extravaganzas of the Hindoo Puranicas, or poetical fabulists. "Brahma, Indra, and all the gods, declare that this largest of mountains is a form consisting of jewels of a hundred colours; the abode of various tribes; like gold; like the dawning morn, resplendent, with a thousand petals; like a thousand water-pots, with a thousand leaves. Within it is adorned with the self-moving cars of the gods, all beautiful; in its petals are the abodes of the gods, like heaven; in it thousand petals they dwell with their consorts. There resides above Brahma, god of gods, with four faces. There in the east is Indra, for ever to be praised; the lord of wealth, with a thousand eyes, the destroyer of towns." (See Indra.) On this Olympia of the Hindoos are all the gods assembled in their magnificent palaces, under different designations. Kailasa is the paradise of Siva. (See Kailasa.) Meru is the grand-father of the river Ganges, as noticed under Mera, the name of his daughter. Under the articles Linga, Lotos, and Yoni, some mention is made of this wonderful mountain; and the reader, desirous of farther accounts of it, and of mysticisms connected with it, is referred to vol. viii. of the Asiatic Researches, and to Moor's Hindoo Pantheon.

MERVILLE, Michael Guyot de, in *Biography*, a French writer, was born at Versailles in 1696. After travelling through various countries, he settled as a bookseller at the Hague, where he published a literary journal. His affairs becoming embarrassed, he went to Switzerland, and drowned himself in the lake of Geneva in 1765. He wrote, 1. Voyage Historique, 2 vols. 12mo. 2. Several Comedies, &c. published at Paris, in 3 vols. 12mo.

Merville, in *Geography*, a town of France, in the department of the North, and chief place of a canton, in the district of Hazebrouch; 15 miles W. of Lille. The place contains 5302, and the canton 16,608 inhabitants, on a territory of 60 kiliometres, in 5 communes.

MERUIT Quantum, in *Law*. See Quantum.

MERULA, George, in *Biography*, a critic and historian, one of the revivers of ancient literature, was a native of Alessandria in Italy. He acquired the rudiments of Latin and Greek under able preceptors, was soon distinguished for his classical attainments, and passed the greatest part of his life in teaching the languages and rhetoric at Venice, Milan, and Pavia. He died at Milan, at an advanced age, in 1494. He was celebrated as an original writer, and as an editor and commentator. Under the patronage of Lewis Sforza he wrote "Antiquitates Vicecomitum, sive de Gestis ducum Mediolanensium," of which the first decade was published in his life time, and four books of the second decade were given in the 25th vol. of the "Scriptores Rerum Ital." He also composed a description of Montserrat, and of the eruption of mount Vesuvius, and a small historical tract entitled "Bellum Scodrense," descriptive of the siege of Scutari by the Turks in 1474. He was the first who gave an edition of the four Latin writers on agriculture, *viz.* Cato, Varro, Columella, and Palladius, with notes, 1472. In the same year he gave the first edition of the "Comedies of Plautus." He likewise either first published or illustrated "Juvenal;" "Martial;" "Ausonius," and the "Declamations" of Quintilian. He translated from the Greek, the lives of Trajan, Nerva, and Adrian. To him the world is indebted for the discovery of many ancient MSS. in the monastery of Bobbio in 1494. Gen. Biog.

Merula, Paul, was born at Dordrecht, in Holland, in the

the year 1558. He acquired in his own country a profound knowledge of law, hiſtory, and polite literature, and then travelled for improvement into France, Italy, Germany, and England. On his return he was appointed to ſucceed the famous Lipſius as profeſſor of hiſtory at Leyden, an office which he held for fifteen years. He died in 1607; leaving behind him ſeveral learned works, as "The Fragments of Ennius, with a Commentary:" "Eutropius:" "The Lives of Eraſmus and Junius:" "Coſmographia," a work on ancient geography: "A Treatiſe on Law:" "A Treatiſe on Hunting, with the Laws reſpecting it:" the two laſt are in the Dutch language. After his death his works were collected and publiſhed under the title of "P. Merulæ Opera varia poſthuma," 1684.

Merula, Claudio, da Correggio, (a ſmall town in the ſtate of Modena,) organiſt of the church of St. Marc at Venice in the time of Zarlino, and one of the interlocutors in the "Raggionamento primo" of his "Dimoſt. Harm." where he is called "il gentiliſſimo M. Claudio Merula, ſuaviſſimo organiſta del ſuo tempo"—the ſweeteſt organiſt of his time. He had been maeſtro di cappella to the duke of Parma, and publiſhed "Toccate," or preludes for the organ, engraved on copper plates. The firſt book of his "Cantionum ſacrarum" appeared at Venice in 1578, in 4to.; after this he publiſhed maſſes, pſalms, motets, magnificats, madrigals in three, four, and five parts.

Claudio Merula was one of the firſt who attempted dramatic muſic. In 1574, he compoſed a theatrical piece at Venice, which was performed in the grand council chamber, for the entertainment of Henry III. of France, when he returned from Poland on the death of his brother, Charles IX. This piece was called a tragedy, and was probably declaimed, with madrigals and choruſſes intermixed.

Merula, Tarquinio, *il Cavalier*, a whimſical compoſer of Bergamo; in the tenth vol. of whoſe works, printed at Venice in 1655, moſt of his inſtrumental movements are compoſed on a ground-baſe, which ſoon after became a common practice with Stradella, Purcell, and others. This maſter was a church compoſer, and a madrigaliſt; but his favourite ſtyle ſeems to have been the burleſque: in his cantata of Curtius for a baſe voice, publiſhed in 1638, the poet, after adviſing Curtius againſt ſo raſh a ſtep, tells him, that though he may eaſily find his way to the bottom of the gulph into which he was about to plunge, yet, he adds, *quanto al ritornare, ſarà un difficile* PASSO; to which laſt word a diviſion of ſix bars, of ſixteen ſemiquavers in each, is given, in the courſe of which, the finger is carried from D on the ſixth ſpace in the baſe, down to the abyſs of double C. There is another diviſion of ſeven bars at the laſt cloſe, in which the paſſages are echoed, piano, and the trill of the times in iterations of the ſame note, in ſemiquavers, is written twice at full length.

The cavalier Merula's compoſitions are almoſt all ſo tinctured with caprice and buffoonery, as to render them more ſingular and new at leaſt than thoſe of his contemporaries. In his "Libro ſecondo della Muſiche concertate," publiſhed in 1635, he has publiſhed a three-part ſong, with ritornels for two violins and a baſe, ſopra la ciacona, with his cantata of "Curzio precipitato." Among other capricious things in this publication, there is a Canzonetta ſpirituale ſopra la Nanna, or Lullaby, conſiſting of only theſe two notes in the baſe:

He has compoſed a learned fugue in four parts, on the declenſion of *Hic, hæc, hoc;* and another upon *Quis vel qui: nominativo qui, quæ, quod, &c.* This laſt conſiſts of ſeveral movements which are ſupported with vivacity, and imitations of the cant and ſtammering of ſchool-boys in repeating their grammatical leſſon. The ſingle vocal airs of this period by Merula and others, which we have examined, in order to trace the progreſs of Italian melody, *ab ovo*, are dull, monotonous, and inelegant. Imagination, as yet, was too much fettered by canto fermo, canon, fugue, and eccleſiaſtical modes, to attempt the uſe of her wings.

Merula, in *Ichthyology*, a ſpecies of *Labrus;* which ſee.

Merula *Fluviatilis*, a name given by Schoneveldt, and ſome other writers, to the common tench. See Cyprinus *Tinca*.

Merula, in *Ornithology*, the *Black-bird*, a ſpecies of *Turdus*, of which there are ſeveral varieties. See Turdus *Merula*, &c. For other ſpecies of *Merula*, ſee Alauda, Corvus, Gracula, Lanius, Muscicapa, Oriolus, Paradisea, Sturnus, and Tanagra.

Merula *Aquatica*, the name of a bird called the *water-ouzel* in Engliſh. Sea Sturnus *Cinclus*.

Merula *Saxatilis*. See Turdus *Saxatilis*, Lanius *Infauſtus*, and Corvus *Caryocatactes*.

MERULIUS, in *Botany*, a name of far-fetched etymology and meaning; adopted by Haller, for the genus which now retains it, from John Bauhin, who in his *Hiſtoria* v 3. 807, mentions ſome fungi as called by the name of *Merulius* or *Metulius*, from *Meta*, a pillar or boundary-poſt with a round top, which their ſhape reſembles. Such fungi, no doubt, are numerous, belonging to various genera; but the idea is leſs ſuitable to our preſent *Merulii*, than to moſt others. —Hall. Hiſt. v. 3. 150. Perſ. Syn. 488. (Cantherellus; Juſſ. 4. Lamarck Illuſtr. t. 883.)—Claſs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eſſ Ch. Cap fleſhy or membranous. Receptacle veiny, with ſuperficial ſwelling plaits.

Perſoon defines 25 ſpecies of this very well-marked genus, whoſe fructifying membrane reſembles the gills of an *Agaricus* in appearance only, being totally diſtinct in nature. Its ſurface is perfectly continuous, but pinched up, as it were, into ſimple or branched tumid plaits.—The genus is divided into three ſections; 1ſt, the true *Cantherelli*, which have an entire, rather cup-ſhaped cap, with or without ſtalk, and conſiſt of 20 ſpecies; 2d, *Serpulæ*, four ſpecies, which ſpread indeterminately, fructifying on the upper ſide, and have no ſtalk; 3d, *Gomphus*, one ſpecies, of a club-like but truncated ſhape, which we think might be referred to the firſt ſection.

Examples of the firſt ſection are,

M. *Cantharellus*. Common Chanterelle. Perſ. n. 1. (M. n. 2326; Hall. Hiſt. v. 3. 150. Agaricus Cantharellus; Linn. Sp. Pl. 1639. Hudſ. 609. Fl. Dan. t. 264. Bull. t. 505. f. 1. Sowerb. t. 46. Bolt. t. 62. A. n. 73; Schæff. t. 82, and n. 95. t. 206. Fungus anguloſus, et velut in lacinias diſſectus; Vaill. Paris. 60. t. 11. f. 14, 15.) —Cluſtered, deep yellow all over. Cap fleſhy, ſmooth, depreſſed.—Very frequent in fir woods. It varies in the breadth of its top, from one to near three inches, and is entirely of the colour of yolk of egg, with an agreeable ſcent like a plum or apricot, eſpecially when drying. This fungus is eaten in many countries, and ſeems to be no otherwiſe unwholeſome, than as its toughneſs renders it indigeſtible. Haller reports the flavour to be excellent, though ſomewhat acrid, and ſays he had often eaten this *Merulius* dreſſed in meat broth, without any bad effects.

M. *nigripes*. Black-ſtalked Chanterelle. Perſ. n. 3. (Agaricus cantharelloides; Bull. t. 505. f. 2.)—Cap funnel-ſhaped, yellowiſh. Stalk elongated, black, and ſooty.

—Native of France. Persoon seems to have adopted it from Bulliard. The taller, more slender, black *stalk*, and more excavated top of the *cap*, seem the principal marks of distinction between this and the first species, of which Mr. Sowerby esteems it a variety only.

M. *lutescens*. Yellowish-stalked Chanterelle. Pers. n. 4. (Agaricus cantharelloides; Sowerb. t. 47. Helvella cantharelloides; Bull. t. 473. f. 3.)—Cap umbilicated, smooth; yellowish-brown above; reddish ash-coloured beneath. Stalk yellow, hollow.—Not uncommon in woods in autumn, according to Persoon, but it seems to have been first observed in England by Mr. Sowerby, Nov. 1794, in Peckham wood. This is clearly distinguished by its hollow pale-yellow *stalk*, and the reddish buff of its fructifying membrane, contrasted with the light brown of the upper surface.

M. *cornucopioides*. Cornucopiæ Chanterelle. Pers. n. 8. (Peziza cornucopioides; Linn. Sp. Pl. 1650. Sowerb. t. 74. Bull. t. 150. Bolt. t. 103. Elvela, n. 17. Schæff. t. 165, and n. 18. t. 166.)—Clustered, blackish, trumpet-shaped, with a wavy reflexed margin; the upper surface scaly; fructifying membrane blueish, with obsolete plaits.—Common in woods in autumn. Distinguished by its invertedly conical trumpet-like shape, with scarcely any *stalk*, the central hollow of the *cap* running down the middle, almost to the root, so as to form a funnel, the outside of which is really the under side of the *cap*, and bears a blueish powder, presumed to be the seed. The plaits of this part are in general sufficiently obvious to mark the genus, though often evanescent. An essential difference exists between this fungus and *Peziza*, the latter producing its seeds from the strongly-coloured upper side of the cap, or cup.

M. *retirugus*. Reticulated Sessile Chanterelle. Pers. n. 16. (Helvella retiruga; Bull. t. 498. f. 1.)—Sessile, vertical, roundish, thin and membranous; smooth and pale grey above; ash-coloured, with radiating reticulated plaits beneath.—This pretty species was found in France by Richard, growing parasitically upon mosses and other plants, affixed by its smooth upper side. The margin is entire when young, but subsequently torn or lobed. The *stalk* is wanting in this, and two or three others of the first section, and Persoon seems doubtful whether they ought not to range in the next. Their membranous nature, and determinate form, with the presence of a proper upper surface, surely justify their remaining where he has placed them.

The second section (which is Persoon's third, as he divides the former into two, because some have a central stalk, and others a lateral one, or none at all) comprises four species, whose shape is quite indeterminate, the whole fungus being reversed, or laid on its back, without any stalk, and almost without any upper surface. The fructification is rare, or tardily produced. The most remarkable is

M. *destruens*. Dry-rot Merulius. Pers. n. 21. (Boletus lachrymans; Wulf. in Jacq. Misc. Austr. v. 2. 111. t. 8. f. 2. Dicks. Crypt. fasc. 1. 18. Sowerb. t. 113.)—Widely spreading, indeterminate, yellowish-red, with a white downy edge. Plaits widely reticulated. The nature of this formidable fungus has not been known till within a few years, though its effects have been but too notorious in countries where much fir wood is used for building. The plant insinuates itself in the form of a fine web, like a sort of mouldiness, amongst the timbers or wooden walls of a house, which it speedily and effectually destroys, so that in Sweden, where houses of fir are common, their unexpected downfall is by no means unfrequent. Mr. Sowerby informs us of this pest having lately attacked some ships in the British navy, concerning which he has been consulted by the navy commissioners. The cure for this evil is the admission of air into all such structures, which is fatal to the growth of the plant. Where this vegetable thrives, but meets with a check to its increase by walls or otherwise, it thickens greatly, and produces a sort of orange-coloured honey-comb structure, containing the *seeds*, and discharging large drops of fluid here and there, as expressed in Mr. Sowerby's plate, justly commended by Persoon.

M. *vastator*, Pers. n. 22, seems very nearly akin to the last.

The third section consists of only one species,

M. *clavatus*. Club-shaped Chanterelle. Pers. n. 25. (Clavaria truncata; Schmid. Ic. t. 60.)—Club-shaped, abrupt, solid, with lateral plaits.—Found in grassy places in Germany, generally growing in tufts. The colour is violet, dull purple, or brownish. The shape is that of a *Clavaria*, either simple or branched; the top abrupt and flat, evidently, though narrow, analogous to the usual upper surface of the cap of a *Merulius*; the sides of the club-shaped body below being plaited or veiny, like the fructifying part of the other species.

MERY, John, in *Biography*, a distinguished anatomist and surgeon, was born at Vatau, in Berry, where his father practised surgery, in January 1645. From his earliest years he displayed an exclusive attachment to the profession of his father, and at the age of eighteen went to the great hospital at Paris, the Hôtel Dieu, where he pursued the study with extraordinary ardour. So earnest, indeed, was he in this pursuit, that whenever he could procure a body, he conveyed it to his bed-room, and passed the night in dissection. In 1681 he was promoted to the office of queen's surgeon; and in 1683 he was appointed surgeon-major to the invalids, at the instance of M. de Louvois, who justly estimated his zeal and talents. In the following year, when the king of Portugal applied to Louis XIV. to send a surgeon to Lisbon to attend upon the queen, he was sent post to that capital; but the queen died before his arrival. Both the courts of Spain and Portugal attempted, by very advantageous offers, to induce him to remain in the peninsula, but he declined them, and returned to Paris. He was now, 1684, received into the Academy of Sciences; and he was soon afterwards sent on a journey to England, by order of the court; but the object of this mission was never made public. He was also chosen by the monarch to attend upon the duke of Burgundy, then a child. Attendance on a court, however, as Fontenelle remarks, was not less irksome to him at home, than in Spain or Portugal, and he returned as soon as it was in his power to the hospital of invalids, and to the dissecting room.

He lived in retirement from all society, as far as it was possible, shutting himself in his closet as soon as he had performed the ordinary duties of his office, which he transacted very methodically: he was not seen even by his family, except at his hours of repast; and declined all solicitations to engage in private practice, except for the service of a few friends. In 1700 he was appointed first surgeon to the Hôtel Dieu, which gratified his utmost ambition, and afforded him abundant opportunities of gratifying his zeal in the pursuit of knowledge, for which he voluntarily sacrificed all considerations of rank and emolument. His high reputation for anatomical knowledge brought many requests from foreigners to give lectures upon that subject; which, however, he declined. But he procured for the students of the Hotel Dieu the erection of a theatre, in which they might obtain a regular course of anatomy, instead of the casual instructions which they had hitherto received; and he expected no additional

 tional

tional recompence for his increased trouble. It was a great part of the labour of his life to form an anatomical museum, which at length he rendered extremely curious and complete. For this purpose, he secluded himself in the most minute and patient dissections; and no man surpassed him in the accuracy with which he investigated facts relative to the construction of the human body. Nevertheless, he justly entertained a very humble opinion of the extent of information, which the knife of the anatomist can bring before the mind, in regard to the minute operations of the animal economy; and was accustomed to say ingenuously, "we anatomists are like the porters of Paris, who are well acquainted with all its streets, as well as its lanes and alleys, but know nothing of what passes within the houses." From the steady occupation of the investigation of facts, he was not in the habit of inventing theories, and did not readily admit the reasonings of others; at the same time, he did not easily renounce his own, when he thought them well founded on observation. Being little used, likewise, to the forms of polite conversation, he stated his views with great plainness, and used no ceremony in contradicting opinions and assertions, which he thought absurd or unfounded in fact; whence he sometimes gave offence at the meetings of the Academy without intending it. In his moral habits he was extremely regular, and always had a high sense of religion. He was married, and had several children. About the age of seventy-five, he suddenly lost the use of his legs, without any other indisposition; but from that time his health and strength began to be impaired, and he died in 1722, in his seventy-seventh year.

In addition to a great number of valuable communications, which were printed in the Memoirs of the Academy of Sciences, Mery published the following works separately. 1. "Description de l'Oreille de l'Homme," Paris, 1681, which was annexed to Laney's work "De l'Ame sensitive," by which he anticipated Duverney, who was known to have been long employed on the same subject. 2. "Observations sur la Manière de Tailler dans les deux Sexes, pour l'Extraction de la Pierre, pratiqueé par Frère Jacques," ibid. 1700, 12mo. This is a very scientific and candid discussion of that celebrated empiric's method of cutting for the stone, the general principle of which he approves, while he points out many mischiefs in his operations, occasioned by his ignorance of anatomy, and the rudeness of his instruments. 3. "Nouveau Systeme de la Circulation du Sang, par le trou ovale, dans le Fœtus humain, avec les Reponses aux Objections de M. M. Duverney, Tauvry, Verheyen, Sylvestre, et Buissiere," ibid. 1700, 12mo. The controversy upon this question was carried on with ardour. Mery controverted the received opinion, that part of the blood passes from the right to the left ventricle, through the foramen ovale, and maintained that its passage was in the opposite direction; and, therefore, that the greater part of the blood in the fœtus circulated through the lungs, and the smaller portion through the rest of the body. It is singular, as Senac remarks, in his treatise on the heart, that Mery, who was in error, had the greater number of partizans; but Duverney and the rest defended the question ill. 4. His last work, "Problèmes de Physique," ibid. 1711, 4to., relates to the connection of the fœtus with the mother, and its nutrition, which he maintains, in opposition to Falconet, to be effected by means of the maternal blood alone, and not by any lacteous fluid, produced in the uterus for that purpose. Eloy Dict. Hist. de la Med. Fontenelle, Eloges des Acad. Gen. Biog.

MERY-*sur-Seine*, in *Geography*, a town of France, in the department of the Aube, and chief place of a canton, in the district of Arcis-sur-Aube; 15 miles N.W. of Troyes. The place contains 1164, and the canton 9849 inhabitants, on a territory of 330 kiliometres, in 26 communes. N. lat. 48° 30′. E. long. 3° 58′.

MERYTA, in *Botany*, from μηρυω, *to collect in clusters*, alluding to the situation of the flowers. Forst. Gen. t. 60. Juss. 442. Lamarck Illustr. t. 803. Class and order, *Dioecia Triandria*. Nat. Ord. uncertain.

Gen. Ch. Male *flowers* aggregate in close heads. *Cal.* Perianth in three deep, ovate, acute segments. *Cor.* none. *Stam.* Filaments three, capillary, the length of the calyx; anthers oblong, with four furrows.

Female *flowers* not discovered.

1. M. *lanceolata*. Forst. Prod. 92.—Native of the Society isles.—The male flowers are represented in an hemispherical, lateral, sessile head. This is all the information extant respecting the genus in question; except that we find, by a note of the younger Linnæus, that sir J. Banks and Dr. Solander had likewise described it as new, by the name of *Neasa*.

MERZAPOUR, in *Geography*, a town of Bengal; 15 miles N.N.W. of Moorshedabad.—Also, a town of Hindoostan, in the country of Benares, seated on the Ganges; 24 miles W.S.W. of Benares. N. lat. 25° 10′. E. long. 82° 50′.

MERZBERG, a town of Silesia, in the county of Glatz, which has a silver mine; 10 miles S. of Glatz.

MERZIFOUR, a town of Asiatic Turkey, in Natolia; 30 miles S. of Samsun.

MES, a river of Persia, which runs into the Tab, near Ragian.

MESA, CHRISTOVAL DE, in *Biography*, a Spanish poet, who lived five years in habits of intimacy with Tasso. He is the author of three heroic poems. 1. "Las Navas de Tolosa," 1598, upon the great victory won at Madrid by Alonzo VIII. over the Moors. 2. "La Restauracion de Espana," 1607, of which Pelayo is the hero. 3. "El Patron de Espana," 1612, in honour of Santiago. Besides these works he published some smaller pieces, as a tragedy upon Pompey, and a translation of the whole of Virgil; and he left in MS. a version of the Iliad. Gen. Biog.

MESA, in *Geography*, a river of Russia, which discharges itself in the Tazovskaia gulf, N. lat. 68° 12′. E. long. 79° 14′.

MESA, *La*, the southernmost of four isles in the Pacific ocean, near each other, and E. of the Sandwich isles. N. lat. 19°. W. long. 137° 10′.

MES-AIR, or MEZAIR, in the *Manege*, is a manege half *terra a terra*, and half *corvet*: so that the mezair is higher than the action of the former, and lower than that of the latter. In this action use the same aids as in working upon curvets. Give the aids of the leg with delicacy, and no stronger than is just necessary to carry your horse forward. Remember when you close your legs to make him go forward, to push with the outward in such a degree as to keep your horse confined, and to assist the other in driving him forward; as it is not necessary to lay so much stress on the inner leg, because that serves only to guide the horse, and make him cover and embrace the ground that lies before him. Berenger's Horsemanship, vol. ii. p. 116.

MESANA, in *Geography*, a town of Hindoostan, in Guzerat; 35 miles N. of Amedabad.

MESANGE of Buffon, in *Ornithology*. See MOTACILLA and PARUS.

MESANGIA, the name of a bird common in France and Italy; it is of the size and shape of the ficedula, and

and differs from it very little, except the having a black spot upon the head. This seems to be the melancoryphos of the ancients, who supposed, as many do at this time, that the ficedula changed into this bird. The ficedula, or fig-eater, comes into the gardens in France only at the time when the figs, which are its proper food, are ripe: these it devours in an insatiable manner, and, as soon as it has done with them, goes away again. Soon after this the mesangia or black-cap appears, and is supposed to be the same bird, with the addition of this beautiful ornament. The ancients were very fond of this imaginary change of one bird into another; and Aristotle tells us, that the upupa is the same bird with the cuckoo, only changed in the colour and disposition of its feathers. Æschylus tells us in the same manner, according to the opinion of his times, that the cuckoo sings all the summer, and after that disappears; and that soon afterwards it comes again in a new form, with a plume upon its head, and is called the *upupa*.

MESARAIC, in *Anatomy*, a term applied to the blood-vessels, glands, &c. of the mesentery.

MESAYEH, in *Geography*, a town of the Arabian Irak, on the Euphrates; 50 miles S.S.W. of Bagdad.

MESAZONTES, μεσαζοντες, officers under the emperors of Constantinople. See MEDIATOR.

MESCHEDIZAR, in *Geography*. See MEDSHETISAR.

MESCHETWIND, a town of Bavaria, in the principality of Bamberg; seven miles S.W. of Forcheim.

MESCHID, a town of the Arabian Irak, near a large lake called "Rahemat," which communicates by a canal with the Euphrates. This is the place in which Ali, Mahomet's cousin and friend, and one of his successors, is said to have been interred; and his tomb is annually visited by a multitude of Persian pilgrims, who deem it a part of devotion equal to the pilgrimage to Mecca; 90 miles S. of Bagdad. N. lat. 32° 5'. E. long. 43° 34'.

MESCHID-*Hussain*, a town of the Arabian Irak, situated on a canal which passes from the Euphrates to the lake Rahemat; 53 miles S.S.W. of Bagdad. N. lat. 32° 36'. E. long. 43° 29'.

MESCHID, or *Maschid*, a city of Persia, in the province of Khorasan. Abas I. raised this place, which was small and called "Tus," to eminence, by erecting a magnificent mosque in honour of an Imam who was buried there, and which drew together a great number of pilgrims. This town has a manufacture of beautiful pottery, and also a manufacture of skins. In time of peace caravans pass continually through this town from Bucharia, Balk, Candahar, Hindoostan, and all parts of Persia. N. lat. 37° 35'. E. long. 57'.

MESCHIDABAD, a town of Asiatic Turkey, in Natolia; 25 miles S.S.W. of Amasreh.

MESCHIQUIEJOS, a town of South America, in the province of Carthagena; ten miles S. of Mompox.

MESCINZUNGH, a town of Thibet; 30 miles W. of Tankia.

MESCOLANZA, Ital. mixture: as mescolanza dell' antica e moderna, a mixture of ancient and modern music.

MESE, in *Geography*, a small island in the East Indian sea. N. lat. 6 55'. E. long. 131° 50'.

MESÉ, in the *Ancient Greek Music*, the name of the most acute sound of the second tetrachord. It implies *mean*: as it was in the middle of the great system, and an octave above the proslambanomenos.

Euclid calls mese the sound by which all other sounds are regulated. And Aristotle, in his 36th problem, sect. 19, says, that all the tones of a scale are accommodated or tuned to the mesé. See MUSIC *of the Ancients*.

MESEMBRIA, or MESSOURI, in *Geography*, a town of European Turkey, in Romania, at the mouth of a river which runs into the Black sea; formerly a bishop's see; 16 miles E.N.E. of Burgas. N. lat. 42° 38'. E. long. 27° 47'.

MESEMBRYANTHEMUM, in *Botany*, a vast genus of succulent plants, formerly known by the name of *Ficoides*, from its affinity to the Indian Fig, or *Cactus*. Breynius first named it *Mesembrianthemum*, meaning to express its flowers expanding at mid-day, which is true of many of the species, but not of all. Dillenius therefore, by altering one letter in the orthography, had recourse to another etymology, from μεσος, *the middle*, εμβρυον, *an embryo*, and ανθος, *a flower*; because the embryo (meaning the germen) is in the middle of the flower; which indeed, as that author most truly remarks, is the case with innumerable plants besides, but not exactly as in the present genus. He observes that the flower does not altogether stand on the top of the fruit, but is perforated, as it were, by the latter, whilst it so closely adheres to the middle, as not to be separable from it without laceration. We confess our predilection for the original idea of Breynius, which if not strictly applicable to all the species, one or more of which are night-scented flowers, is strikingly apposite to the generality, whose refulgent and radiating petals seem to welcome, as well as to emulate, the noon-tide sun, folding themselves up as it withdraws. Fig-Marigold.—Dill. Elth. 225. Linn. Gen. 252. Schreb. 340. Willd. Sp. Pl. v. 2. 1025. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 212. Juss. 317. Lamarck Dict. v. 2. 474. Illustr. t. 438. Gærtn. t. 126. —Class and order, *Icosandria Pentagynia*. Nat. Ord. *Succulentæ*, Linn. *Ficoideæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, in five acute, spreading, permanent segments. *Cor.* Petals numerous, linear-lanceolate, in many rows, rather longer than the calyx, slightly united into a tube by their claws. *Stam.* Filaments numerous, capillary, the length of the calyx, inserted into its fleshy part within the petals; anthers incumbent. *Pist.* Germen inferior, with five obtuse angles; styles generally five, sometimes four or ten, awl-shaped, spreading; stigmas simple. *Peric.* Capsule fleshy, roundish, marked with rays at the summit, the cells and valves each answering to the styles in number. *Seeds* numerous, roundish, affixed to the central column.

Eff. Ch. Calyx five-cleft. Petals numerous, linear, cohering at the base. Capsule fleshy, inferior, with many seeds.

Fifty species of *Mesembryanthemum* are defined in the 14th ed. of *Syst. Veg.* disposed in three sections, distinguished by the flowers being white, red, or yellow. Thunberg in his Prodromus has but 72; Willdenow mentions 86; but the new edition of the *Hortus Kewensis* enumerates 175. The labours of Mr. Haworth, who has published, in an octavo volume, an ample Monograph of the present genus, and who has, for many years, investigated and cultivated all the species he could procure, has thrown great light upon the subject, though we are not able to follow him in all that he describes, for want of having seen them so completely. They are almost exclusively the productions of the arid sands of the Cape of Good Hope; a very few only being found in New Holland, and New Zealand, or in the south of Europe. We shall therefore mention the native countries of such only of those we are about to particularize, as are found in other places, though even these are often likewise natives of the Cape; as the *crystallinum* and *nodiflorum*. There they are all at home. Their peculiarly succulent nature, like that of Aloes, is calculated to resist the

the burning ſun and long-continued drought of that climate, their cuticle allowing of very ſlow perſpiration, though of ready abſorption; ſo that however exhauſted they may be, they revive from the ſlighteſt ſhower. This wonderful proviſion of nature exiſts only in the living plant. When killed by momentary immerſion in hot water, theſe ſucculent plants dry nearly as quick as any others. The horticulturiſts of Europe are beſt acquainted with the numerous perennial ſpecies of the genus before us. There have indeed been ſome annual ones raiſed here, but we have reaſon to think there are many almoſt entirely unknown. Some of theſe bear very curiouſly-conſtructed capſules, which expand by moiſture, contrary to the nature of capſules in general, that their ſeeds may be diſperſed in the wet ſeaſon, when alone they would, in ſuch a country, have any chance of germinating. (See Sm. Introd. to Botany, 277. f. 178.) —We ſhall mention a few ſpecies of each of the 13 ſections into which this genus is diſtributed in *Hort. Kew.*

1. *Stemleſs; inverſely conical, or obcordate, or more rarely ſpherical, the leaves being extremely abrupt, and united even to their ſummits, the flowers ſolitary.* Seven ſpecies in Hort. Kew.

M. *minutum.* Tiny Fig-Marigold. Ait. n. 1. Sims in Curt. Mag. t. 1376.—Smooth, glaucous, ſpotleſs, nearly globoſe, umbilicated. Baſes of the petals forming a tube nearly as long as the borders.—This ſingular plant appears a congeries of glaucous balls, each about the ſize of a ſmall gooſeberry, hollowed out at the top, from whence ſprings a roſe-coloured, ſeſſile, ſolitary *flower*, larger than a daiſy, with yellow *ſtigmas*, and a pale tubular baſe, compoſed of the united claws of the *petals*, by which it is elevated much above the *calyx*. This ſpecies bloſſoms from the middle of November to near Chriſtmas, after which it muſt be kept without water through the winter, being preſerved from froſt.—Six more of this curious ſection are deſcribed by Mr. Haworth, and in *Hort. Kew.*, all ſent from the Cape at different times by the late Mr. Francis Maſſon. See Masson.

2. *Nearly ſtemleſs, with a perennial root.* Thirty-eight ſpecies.

M. *calamiforme.* Quill-leaved Fig-Marigold. Linn. Sp. Pl. 690. Willd. n. 20. Ait. n. 16. Dill. Elth. 239. t. 186. f. 228. (Ficoides capenſis humilis, cepæ folio, flore ſtramineo; Bradley Succ. Pl. t. 19.)—Leaves nearly cylindrical, acute, glaucous, finely dotted; flattened juſt above their baſe. Styles eight.—The numerous upright or aſcending *leaves*, about a finger's length, compoſe denſe glaucous tufts. *Flowers* large, of a brilliant white with pale lemon-coloured ſtamens, each on a very ſhort, ſolitary, ſlightly leafy, ſtalk, not ſo tall as the leaves. This is one of the oldeſt inhabitants of our gardens. Bradley publiſhed it in 1717.

M. *felinum.* Cat-chap Fig-Marigold. Haworth n. 35. Willd. n. 11. Ait. n. 29. (M. ringens β; Linn. Sp. Pl. 698. M. rictum felinum repræſentans; Dill. Elth. 240. t. 187. f. 230. Ficoides afra, folio triangulari enſiformi craſſo brevi, &c.; Mart. Dec. t. 30.)—Stem none. Leaves glaucous, fringed with vertical taper-pointed teeth; cartilaginous at the extremity.—This has been long known in England, and thrives well in the dry ſtove, flowering for ſome time during autumn. It is diſtinguiſhed by the idea which its oppoſite *leaves*, fringed with long vertical hooked teeth, convey of the widely-gaping mouth of a cat. The *flowers* are ſeſſile, large, lemon-coloured, opening in the afternoon, and cloſing at night.

M. *tigrinum*, and *caninum* are nearly akin to this; and the latter was confounded with it by Linnæus.

M. *prapingue.* Soft Tongue Fig-Marigold. Ait. n. 38. (M. heterophyllum; Andr. Repoſ. t. 540.)—Leaves tongue-ſhaped, very tender; the younger ones finely fringed, incurved at the point.—This flowered at Mr. Lambert's, at Boyton. The herbage is peculiarly ſucculent and tender, of a graſs green, and ſhining. *Flowers* large, yellow, on ſhortiſh ſtalks. *Capſule* cloſed when dry, expanding with moiſture, as in ſome annual ſpecies abovementioned, and, as it appears by the account in Andrews, (which, if we miſtake not, came from the pen of the late excellent Mr. George Jackſon, ſee Jacksonia), in many perennial ones; perhaps in all the genus.

M. *dolabriforme.* Hatchet-leaved Fig-Marigold. Linn. Sp. Pl. 699. Ait. n. 45. Curt. Mag. t. 32. (M. folio dolabriformi; Dill. Elth. 248. t. 191. t. 237. Ficoides capenſis humilis, foliis cornua cervina referentibus, petalis luteis, noctiflora; Bradl. Succ. Pl. t. 10.)—Stem ſhort. Leaves compreſſed, with a very prominent dilated keel, and a cylindrical baſe.—Although the growth of this ſpecies be very ſlow, it has always more or leſs of a decided thick woody much-branched *ſtem*, ſo that few ſtudents would ſeek it in this ſection. The *leaves* are very peculiarly formed, as above deſcribed, and are the only inſtance of the hatchet ſhape; ſee Sm. Intr. to Bot. 171. f. 98. The *flowers* are plentifully produced, yellow, on longiſh, ſolitary, terminal *ſtalks*, and expand in the evening and night only.

3. *Stems proſtrate. Leaves cluſtered, elongated. Petals yellow, either on both ſides, or on the upper one only.* Five ſpecies.

M. *loreum.* Leathery-ſtalked Fig-Marigold. Linn. Sp. Pl. 694. Willd. n. 48. Ait. n. 46. Dill. Elth. 264. t. 200. f. 255.—Leaves ſemicylindrical, ſomewhat triangular, elongated, recurved, rather glaucous, in round tufts. Stems lax, roundiſh, ſlender, whitiſh. Flowers axillary.—Though this has been generally cultivated in England for above 80 years, nothing is recorded of its blooming. Willdenow however deſcribes the *flowers* as very rarely produced in the collection of Engelbert Gother, each on a ſhort axillary ſtalk, from the lower *leaves* of the branch, with a purple *corolla*, and whitiſh *ſtamens*. The plant is known by its long trailing twine-like *ſhoots*, bearing ſeveral little tufts or knots of *leaves*, and generally dependent over the edges of the garden-pot.

4. *Leaves very long, alternate, cloſely crowded into tufts. Stem decumbent when old. Petals very narrow, fringed from the baſe to the middle.* Three ſpecies.

M. *capitatum.* Short Dagger-leaved Fig-Marigold. Haworth. Ait. n. 52. (M. pugioniforme; Linn. Sp. Pl. 699. Willd. n. 80. M. pugioniforme, flore amplo ſtramineo; Dill. Elth. 280. t. 210. f. 269. Ficoides capenſis, caryophylli folio, flore aureo ſpecioſo; Bradl. Succ. Pl. t. 14.)—"Leaves awl-ſhaped, triangular with equal ſides, glaucous. Membranes of the calyx pale. Petals yellow, as long as the calyx; the outer ones purpliſh. Styles briſtle-ſhaped, ſtraight."—A fine large branching ſpecies, diſtinguiſhed by the great ſize of its *flowers*, which are nearly as broad as the palm of the hand, of a brilliant ſtraw-colour, purpliſh underneath, opening in ſun-ſhine only. The *leaves* are numerous, curved, three or four inches long. This is the original *M. pugioniforme*, and we do not well underſtand why that name ſhould be transferred to another ſpecies, which it ſeems is ſo called in a French work on Succulent Plants, t. 72, and which has more compreſſed *leaves*, the membranes of the *calyx* brown, *petals* entirely ſtraw-coloured, ſhorter than the *calyx*, and linear-lanceolate expanded *ſtyles*.

5. *Leaves flat, often somewhat keeled beneath. Stems often decumbent or prostrate, widely spreading.* Seventeen species.

M. *cryſtallinum.* Ice-plant. Linn. Sp. Pl. 688. Willd. n. 25. Ait. n. 54. (M. cryſtallinum, plantaginis folio undulato; Dill. Elth 231. t. 180. f. 221. Ficoides africana, folio plantaginis undulato, micis argenteis aſperſo; Bradl. Succ. Pl. t. 48.)—Leaves alternate, ovate, waved, papillary. Flowers ſeſſile. Segments of the calyx ovate, broad.—Linnæus, not without reaſon, doubted whether this ſpecies came from Africa. Thunberg, however, found it at the Cape of Good Hope. The late Dr. J. Sibthorp gathered it about Athens. In gardens the plant has long been known, as a tender annual, much admired for appearing as if froſted over; or encruſted with ſugar. This appearance is cauſed by innumerable little bladders in the cuticle, filled with limpid juice. To the touch the whole herb is cold, and remarkably flaccid. Its *ſtem* ſpreads widely on the ground, in a rank mode of growth, bearing numerous broad undulated *leaves*, and copious, nearly ſeſſile, *flowers*, of a pale roſe or fleſh-colour. The *fruit* is dark purple.

M. *pinnatifidum.* Jagged-leaved Fig-Marigold. Linn. Suppl. 260. Willd. n. 23. Ait. n. 55. Curt. Mag. t. 67.—Leaves oblong, pinnatifid, papillary. Flowers axillary, on longiſh ſtalks.—This alſo is an annual, whoſe ſeeds, ſent by Thunberg from the Cape, vegetated in the Upſal garden. The pinnatifid *leaves*, and ſmall yellow long-ſtalked *flowers*, are its characteriſtics.

M. *cordifolium.* Heart-leaved Fig-Marigold. Linn. Suppl. 260. Willd. n. 24. Ait. n. 65. Sm. Spicil. t. 6. Jacq. Ic. Rar. t. 487.—Leaves ſtalked, papillary, heart-ſhaped or ovate. Stem round. Calyx often four-cleft.—Soon after the firſt introduction of this ſpecies, it was common in every green-houſe, but is now rather neglected. The *ſtems* are ſhrubby, though long and trailing. *Leaves* darkiſh green. *Flowers* ſmall, deep crimſon. It is readily propagated by cuttings.

6. *Leaves linear; the younger ones channelled above, convex beneath. Branches often ſomewhat ſhrubby. Root moſtly perennial; rarely annual.* Seventeen ſpecies.

M. *nodiflorum.* Neapolitan Fig-Marigold. Linn. Sp. Pl. 687. Willd. n. 56. Ait. n. 71. (Kali floridum repens Neapolitanum; Column. Ecphr. t. 73.)—Leaves alternate, nearly cylindrical, obtuſe; fringed at the baſe.—Native of the ſea-coaſts of the ſouth of Europe, and north of Africa. *Root* annual. *Stem* branched from the bottom, ſpreading, covered, like the *leaves*, with pellucid watery veſicles, as in *M. cryſtallinum*, but rather leſs glaucous. *Flowers* lateral or axillary, ſeſſile, ſolitary, ſmall and unornamental, with narrow white *petals* and yellow *ſtamens*. The ſegments of the *calyx* are oblong, obtuſe, leafy, very unequal in ſize.

M. *viridiflorum.* Green-flowered Fig-Marigold. Willd. n. 51. Ait. n. 74. Curt. Mag. t. 326.—Leaves ſemi-cylindrical, hairy, ſomewhat papillary. Calyx hairy. Petals capillary. Stem tumid. Branches diffuſe.—A ſhrubby ſpecies, ſingular in having green *petals*, which are very copious, and as narrow as a fine thread. The *herbage* is downy all over, ſlightly glaucous and papillary. It blooms from July to September, and is readily increaſed by cuttings. Mr. Maſſon ſent this from the Cape in 1774.

7. *Evening-flowering; with ſlender, ſhrubby, hard, greatly defoliated ſtems; nearly cylindrical undotted leaves; a four-cleft calyx; fragrant flowers, white on their upper ſide; roots much ſwelled with age, having very few fibres.* Two ſpecies.

M. *noctiflorum.* Night-flowering Fig-Marigold. Linn. Sp. Pl. 689. Willd. n. 41. Ait. n. 88. M. noctiflorum, flore intùs candido, extùs phœniceo, odoratiſſimo; Dill. Elth. 273. t. 206. f. 262.)—Leaves remote, obſcurely ſemicylindrical, diſtinct, glaucous. Bark white.—Highly deſirable for the ſake of its *flowers*, whoſe ſcent in an evening is like the Scarlet *Craſſula*, or the fineſt Bergamot Pear. The *ſtem* is ſhrubby, pale, upright, round, croſs-branched at the top. *Flowers* on longiſh ſtalks, from the ends or forks of the branches, with a thick pear-ſhaped *germen*, and ſhort four-cleft *calyx*, much exceeded by the numerous pale *petals*, whoſe under ſide is either red or yellow.

M. *ſtramineum.* Straw-coloured Sweet Fig-Marigold. Haworth. Ait. n. 89. (M. noctiflorum β; Linn. Sp. Pl. 689. Willd. n. 41. M. noctiflorum, flore intùs candido, extùs ſtramineo, odoratiſſimo; Dill. Elth. 274. t. 206. f. 263.)—Leaves remote, nearly cylindrical, diſtinct, rather glaucous. Bark grey.—Mr. Haworth agrees with Dillenius, who ſtrenuouſly inſiſted on this being ſpecifically diſtinct from the laſt, of which moſt writers make it a variety. The *flowers* are larger, very white above, pale yellow beneath. They expand only in an evening, like the laſt, and ſmell like the Dame's Violet, or Rocket (*Heſperis*).

8. *Flowers generally reddiſh. Branches ſhrubby, ſmooth. Leaves triangular and compreſſed* (except *M. læve*, Ait. n. 93), *naked, with ſtraight points.* Thirty-nine ſpecies.

M. *ſpectabile.* Showy Fig-Marigold. Haworth Meſembr. 385. Willd. n. 73. Ait. n. 98. Curt. Mag. t. 396.—Leaves crowded, triangular, elongated, glaucous, ſomewhat curved. Stem woody, aſcending.—Introduced by Mr. Maſſon in 1787. Its fine large crimſon *flowers*, produced all ſummer long, render this one of the moſt deſirable, nor is it difficult of culture. Mr. Curtis obſerves that the *leaves*, which are very glaucous, and often tinged with red, ſometimes acquire a prominent tooth or appendage on their upper ſide near the point.

M. *acinaciforme.* Scimitar-leaved Fig-Marigold. Linn. Sp. Pl. 695. Willd. n. 83. Ait. n. 116. Andr. Repoſ. t. 580, not 508. (M. acinaciforme, flore ampliſſimo purpureo; Dill. Elth. 282. t. 211. f. 270, and t. 212. f. 271.)—Leaves ſcimitar-ſhaped, dotleſs, combined at their baſe; their margins minutely undulated and rough. Petals lanceolate.—One of the firſt ſpecies brought to Europe, and one of the largeſt and moſt ornamental when it flowers, which unfortunately is but of rare occurrence. Andrews ſays this was accompliſhed by Mr. Trimmer of Brentford, by training the branches up againſt the glaſs, and watering the plant very ſparingly. The *leaves* are numerous, three inches long, very glaucous. *Flowers* terminal, ſolitary, as broad as the hand, formed of innumerable recurved bluntiſh *petals*, of a fine crimſon, with white *filaments* and yellow *anthers*.

M. *edule.* Eatable Fig-Marigold. Hottentot's Fig. Linn. Sp. Pl. 695. Willd. n. 85. Ait. n. 119. (M. falcatum majus, flore amplo luteo; Dill. Elth. 283. t. 212. f. 272.)—Leaves with three equal ſides, dotleſs, ſomewhat channelled; tapering at each end; keel finely ſerrated. Angles of the branches ſmooth and entire.—This is ſaid to have been one of the Cape plants, brought from Holland by the firſt Earl of Portland. It rarely flowers here, and not till the plant is old and woody. It nearly vies with the laſt in ſize, but the *flowers* are yellow. The *fruit* is reported to be eaten at the Cape, both by the Hottentots and the Dutch ſettlers.—The colour of this *flower* is an exception to the character of the ſection, but its cloſe affinity to ſome of the other ſpecies has ſuperſeded that one particular mark.

9. *Flowers yellow, orange, or ſcarlet. Stems rather ſhrubby, often erect. Leaves triangular, for the moſt part very ſhort.* Twelve ſpecies.

M. *aureum.*

M. *aureum.* Golden-flowered Fig-Marigold. Linn. Syst. Nat. ed. 10. v. 2. 1060. Willd. n. 75. Ait. n. 136. Curt. Mag. t. 262.—Leaves triangular, somewhat cylindrical, dotted, distinct. Petals orange. Styles deep purple.—A bushy species, long cultivated here, and easily increased, known by its rather large orange-coloured *corolla*, pale yellow *stamens*, and five purple *styles*, spreading like a star. The *leaves* are glaucous, tumid between their angles, about one inch and a half long. So great a similarity between the species of this section exists in the form of their *leaves*, that botanists are obliged to recur to the colours of the parts of fructification, which experience proves, in this case, to be constant. The *aureum* blossoms from February to May, being one of the earliest of its genus.

M. *tenuifolium.* Slender-leaved Fig-Marigold. Linn. Sp. Pl. 693. Willd. n. 45. Ait. n. 140. (M. tenuifolium procumbens, flore coccineo; Dill. Elth. 264. t. 201. f. 256.)—Leaves semicylindrical, awl-shaped, slightly compressed, green, smooth, longer than the joints of the branches. Petals scarlet. Stems decumbent.—Cultivated at Chelsea in 1700. Its procumbent habit, and slender scarcely glaucous *foliage*, mark this species. The *flowers* are plentiful about Midsummer, rather large, of a light brilliant scarlet, each lasting several days.

10. *Leaves more or less hooked at their points, distinct (without thickened sheaths) at the base. Petals reddish. Stems somewhat shrubby, very rarely creeping.* Ten species.

M. *tuberosum.* Tuberous-rooted Fig-Marigold. Linn. Sp. Pl. 693. Willd. n. 44. Ait. n. 146. (M. fruticescens, radice ingenti tuberosâ; Dill. Elth. 275. t. 207. f. 264.)—Leaves bluntly triangular, compressed, minutely papillary; recurved at the ends. Root tuberous, very large.—Brought from the Cape at the beginning of the last century. The *root* consists of several large ovate knobs, almost like those of a *Dahlia*. *Stems* woody, variously branched and curved. *Leaves* about an inch long, convex above. *Flowers* small, dull red, in terminal dichotomous panicles, whose permanent stalks often become spinous.

The *flowers* in this section are among the least beautiful of the genus.

11. *Leaves triangular, strongly united, so as to be perfoliate; their sheaths fleshy; their tips hooked. Stems hard, woody. Flowers mostly white, rarely reddish.* Twelve species.

M. *perfoliatum.* Great Perfoliate Fig-Marigold. Ait. n. 152. (M. uncinatum β; Linn. Sp. Pl. 692. Willd. n. 79. M. perfoliatum, foliis majoribus triacanthis; Dill. Elth. 251. t. 193. f. 240.)—Leaves strongly united at the base, pointed, dotted; their keel three-toothed at the summit.—A bushy plant, of rather slow growth, remarkable for two sharp teeth, besides the terminal one, at the back of its strongly perfoliate *leaves*. The *flowers* are purple, not frequent, produced after Midsummer.

M. *uncinatum* α of Linnæus and Willdenow, Dill. f. 239, differs in its smaller size, and having but one tooth below the point of the *leaves*.

M. *umbellatum.* Umbel-flowered Fig-Marigold. Linn. Sp. Pl. 689. Willd. n. 42. Ait. n. 162. (M. fruticescens, floribus albis umbellatis; Dill. Elth. 276. t. 208. f. 266. Ficoides africana erecta teretifolia, floribus albis umbellatis; Herm. Parad. 166. t. 166. Bradl. Succ. Pl. dec. 4. 12. t. 44, not 34.)—Leaves rather glaucous, rough with minute dots, remote, elongated, slender; their points recurved; their sheaths greatly thickened upwards.—This, according to Hermann, was early plentiful in the gardens of Holland. The *stem* is often two feet high. *Leaves* two inches long, spreading, channelled above, bearing axillary tufts of smaller ones. *Flowers* white, about as big as a daisy, many together in a forked umbel-like *panicle*, not a real *umbel*.

12. *Stems shrubby, their branches more or less rough.* Five species.

M. *micans.* Glittering Fig-Marigold. Linn. Sp. Pl. 696. Willd. n. 54. Ait. n. 163. Curt. Mag. t. 448. (M. micans, flore phœniceo, filamentis atris; Dill. Elth. 292. t. 215. f. 282.)—Leaves semicylindrical, bluntish, papillary, slightly recurved. Segments of the calyx rather pointed. Petals acute.—An old inhabitant of our greenhouses, distinguished by its glittering, glaucous, often purplish, *leaves* and *branches*, and the very rich orange scarlet of its *flowers*, which however are not so lasting as beautiful. The dark purple *stamens* form a striking contrast with the *corolla*.

Mr. Haworth's *M. speciosum*, Ait. n. 164, seems to us but a variety of this, with blunter *petals* whose claws are green.

13. *Branches, or leaves, or the tips of the leaves, more or less hispid.* Eight species.

M. *hispidum.* Purple Bristly Fig-Marigold. Linn. Sp. Pl. 691. Willd. n. 61. Ait. n. 168. Mill. Ic. t. 176. f. 3. (M. pilosum micans, flore saturantèr purpureo; Dill. Elth. 289. t. 214. f. 277, 278.)—Leaves cylindrical, blunt, papillary, without hairs, as well as the calyx. Stamens longer than the pistils. Branches very hairy.—Common in greenhouses, flowering most part of the year. The very bristly *stem* and *branches*; thick, deflexed, blunt *leaves*, and large *flowers*, of a shining violet purple, distinguish the present from all we have hitherto noticed.

Linnæus made several varieties of this, which are the *floribundum*, *striatum*, and perhaps *hirtellum*, Ait. n. 169, 171, and 170, all nearly akin, but we mean not to say they are one species. The citation of Willdenow under the *floribundum* in *Hort. Kew.* should be *M. hispidum* β.

M. *barbatum.* Trailing Bearded Fig-Marigold. Linn. Sp. Pl. 691. Willd. n. 63. Ait. n. 173. Curt. Mag. t. 70. (M. radiatum, ramulis prolixis recumbentibus; Dill. Elth. 245. t. 190. f. 234.)—Leaves remote, somewhat ovate, tumid, papillary; flattish above; tipped with five radiating bristles. Branches slender, smooth, straggling. Calyx five-cleft.—Very common in greenhouses, and even in the garret windows of many a humble collector. The radiating bristles at the end of the tumid *leaves* are remarkable, and are but about five in this species. The *flowers* appear in July, and are of a rich violet purple. Linnæus by mistake quotes Miller's t. 176. f. 3, for the present plant, instead of the *M. hispidum*. Willdenow has it under both.

M. *densum.* Dwarf Bearded Fig-Marigold. Haworth. Ait. n. 175. Curt. Mag. t. 1220. (M. barbatum γ; Linn. Sp. Pl. 691. Willd. n. 63. M. radiatum humile, foliis majoribus; Dill. Elth. 248. t. 190. f. 236.)—Stem very short. Leaves densely crowded, semicylindrical, papillary, tipped with many radiating bristles; their base somewhat fringed. Calyx six-cleft, very hairy, as well as the flower-stalks.—Dillenius says this was plentiful with him, but he never remembered its blooming. Mr. Haworth kept it 21 years without seeing a flower. We perfectly agree with Dr. Sims that this gentleman has shewn his judgment in separating this, as well as his *hirsutum*, Dill. f. 235, from the *barbatum*, under which Linnæus had confounded them all. The *flower* of the *densum* is twice as large as that of either of the others, with conspicuous yellow *anthers*; and the white membranous starry bristles, at the end of each leaf, are very striking.

Mesembryanthemum, in *Gardening*, comprehends plants of the succulent flowery exotic kinds, of which the species cultivated are, the diamond fig marigold, or ice plant (M. crystal-

cryſtallinum); the pinnated fig marigold (M. pinnatifidum); the plane-leaved fig marigold (M. tripolium); the ſmall flowered fig marigold (M. caducum); the angular-ſtalked fig marigold (M. pupuloſum); the jointed fig marigold (M. geniculiflorum); the night-flowering fig marigold (M. noctiflorum); the ſhining fig marigold (M. ſplendens); the umbelled fig marigold (M. umbellatum); the houſeleek-leaved fig marigold (M. expanſum); the quill-leaved fig marigold (M. calamiforme); the daiſy-flowered fig marigold (M. bellidiflorum); the delta-leaved fig marigold (M. deltoides); the bearded fig marigold (M. barbatum); the briſtly fig marigold (M. hiſpidum); the hairy-ſtalked fig marigold (M. villoſum); the rugged fig marigold (M. ſcabrum); the creeping fig marigold (M. reptans); the hook-leaved fig marigold (M. uncinatum); the thorny fig marigold (M. ſpinoſum); the tuberous-rooted fig marigold (M. tuberoſum); the ſlender-leaved fig marigold (M. tenuifolium); the upright-ſhrubby fig marigold (M. ſtipulaceum); the thick-leaved fig marigold (M. craſſifolium); the ſickle-leaved fig marigold (M. falcatum); the cluſtered fig marigold (M. glomeratum); the two-coloured fig marigold (M. bicolorum); the ſerrate-leaved fig marigold (M. ſerratum); the glittering fig marigold (M. micans); the ſpit-leaved fig marigold (M. veruculatum); the glaucous-leaved fig marigold (M. glaucum); the horned fig marigold (M. corniculatum); the ringent fig marigold (M. ringens); the hatchet-leaved fig marigold (M. dolabriforme); the various-leaved fig marigold (M. difforme); the white fig marigold (M. albidum); the tongue-leaved fig marigold (M. linguiforme); the dagger-leaved fig marigold (M. pugioniforme); the twiſted-leaved fig marigold (M. tortuoſum); the notch-flowered fig marigold (M. emarginatum); and the bracteated fig marigold (M. bracteatum).

In the ſeventh ſpecies there is a variety in which the flowers are ſomewhat larger, and of a very pale yellow on the outſide.

The thirteenth ſort has different varieties; as the great delta-leaved, and the ſmall delta-leaved marigold.

The fourteenth ſpecies has alſo ſeveral varieties; as the ſhrubby, bearded, the ſmall dwarf-bearded, and the great dwarf-bearded.

And in the fifteenth kind there are different varieties; as the purple-flowered, the pale-flowered, and the ſtripe-flowered.

The nineteenth ſpecies likewiſe affords different varieties.

It may be noticed, that the twenty-ſixth ſpecies is very variable, aſſuming different appearances, according to its treatment, and the different ſtages of its growth: its very numerous beautiful purple flowers, covering the whole plant, and produced every ſeaſon, make it a valuable ſpecies in all caſes.

The twenty-ninth ſpecies varies with paler and ſmaller flowers.

And the thirtieth varies with ſhorter and more manifeſtly three-ſided leaves and fewer flowers.

The thirty-ſecond ſpecies has a variety which throws out many procumbent branches, tough at the lower part, but not properly woody, herbaceous at the upper part, about three inches in length, round or ſlightly angular, jointed at ſhort intervals, with bluntly triangular leaves, from which other leaves ſpring in bundles, of the ſame form but ſhorter; the root-leaves and thoſe at the baſe of the branches remarkably long: the leaves bend like the horns of kine, whence the trivial name.

In the thirty-third ſpecies there is a variety which is entirely ſeſſile, of a whitiſh glaucous colour, with the leaves pale at the baſe, with frequent round whitiſh dots, eſpecially towards the end; they are ſhorter than thoſe of the original, more reſupine, leſs triquetrous, but with a rounder back, and more frequent, longer incurved prickles, terminated by ſlender harmleſs ſpinules, which are ſometimes white, ſometimes reddiſh: the leaves have a white line at the end, which is continued towards the back: there is firſt a flower in the middle, and afterwards ſeveral come out ſucceſſively at the ſides, all ſeſſile. This is called *Cat-chap marigold.*

Mr. Haworth has two other varieties; the *Tiger-chap fig marigold*, which is ſtemleſs in all the ſtages of its growth; being more ſucculent and groſs than the following: the leaves are rather ſhorter, beſet with much longer hairs on the ſides, and having numerous whitiſh ſpots: the flowers are ſeſſile, yellow, and large; and the *Mouſe-chap fig marigold*, in which the branches in very old plants are ſome inches long, and numerous, forming a fine tufted plant; the flowers ſmall and of a yellow colour.

The thirty-ſeventh ſpecies has ſeveral varieties.

In the firſt the leaves are wide and compreſſed about the edge; the flowers ſomewhat large, with blunt petals, ſcattered and not numerous, with ſcarcely any peduncle; one plant has ſeveral heads, from each of which are produced cluſters of leaves in pairs, diſpoſed like thoſe of the Tongue aloes, but with the edges not horizontal but oblique; there are generally three or four pairs of theſe leaves; they are broad and thick, flat above, pillowed below, bright green, ſmooth and ſhining, ſometimes blunt, ſometimes a little pointed, generally in the ſhape of a ſhoemaker's knife; the younger leaves in this and the other *varieties*, are folded together and obliquely inſerted into each other; the flowers come out ſucceſſively in Auguſt and September from the axils, beginning with the loweſt; they are ſubſeſſile, large, yellow, ſomewhat paler than in the following variety, ſhining in the ſun; petals ſomewhat blunter, entire, or ſometimes cut here and there.

The *Broad tongue-leaved* variety has thick leaves, flat above, convex beneath, with the margins thicker and leſs upright than in the preceding, ſmooth and ſhining, pale green, eſpecially towards the baſe, when held up to the light appearing to be compoſed of innumerable veſicles; three or four pairs of theſe leaves lie in the ſame inclined plane; theſe are ſometimes flatter and blunt at the end, ſometimes very much cut at the edge; from the lower pair firſt, and then from the next, a ſhort peduncle ariſes, obtuſely triquetrous, bearing a large flower of a ſhining golden colour, with many ſtamens, having oblong golden anthers.

The *Narrow tongued-leaved* variety is very like the preceding, but the petals have a ſlight tinge of red on the outſide; the older leaves are more reflex; the younger ones, which are cloſer and more luxuriant, are ſomewhat twiſted in and excavated, and are of a fuller green colour, the fruit is ſmaller and ſofter, not elevated, but rather depreſſed, roundiſh, and commonly ſtreaked with eleven angles; it is generally eleven-celled; the cells being the ſame in number as there are horns of the ſtyle, which are depreſſed at the bottom of the flower under the ſtamens, and are curled and wrinkled; the petals in two or three rows, almoſt of the ſame length, of a ſhining yellow colour.

There is another variety, which is diſtinguiſhed from the others by the leaves being longer and more erect; the peduncles of the flowers longer; the capſules leſs globular, commonly divided into nine cells; the calycine ſegments four, three longer and narrower, one ſhorter and broader, with a membranaceous margin; the flowers have a double or triple row of petals, ſhining in the ſun with the ſplendour of of gold; the ftamens numerous, with oblong faffron-coloured anthers.

Method of Culture.—Thofe of the annual and biennial kinds may be increafed by fowing the feeds in the early fpring months on a frefh hot-bed, covered with fandy earth, or in pots of fine fandy mould. And when the plants have attained a few inches in growth they may be planted on frefh hot-beds, or in pots plunged in them, to bring them forward; and as foon as they have taken root, they fhould have very little water; when of fufficiently large fize, each fhould be planted in a fmall pot, filled with light frefh earth, but not rich, plunging them into a hot-bed of tan, fhading them in the heat of the day until they have taken new root, when they fhould have plenty of frefh air. About the beginning of fummer fome of the plants may be inured to the open air, and afterwards be turned out of the pots, and planted with balls of earth about them in a warm border, where they often thrive and fpread, but are not very productive of flowers in this way. Some muft alfo be continued in pots, and removed to the fhelves of the ftove, where they flower more plentifully.

The only culture which they afterwards require is, for thofe in the pots to have frequent flight waterings in dry weather, and the others to be kept clean, and their branches permitted to fpread upon the furface of the ground.

All the perennial forts may be readily increafed by cuttings planted during the fummer months. Thofe having fhrubby ftalks and branches, readily take root when planted out in beds or in pots of light fandy foil, covered with mats or glaffes; in the latter cafe, being fhaded when the fun is warm. The cuttings of thefe forts need not be cut from the plant more than five or fix days before they are planted, during which time they fhould be laid in a dry room, not too much expofed to the fun, that the parts which are feparated from the old plants may heal over and dry, otherwife they are apt to rot. They may then be planted at about three inches diftance from each other, the earth being preffed very clofe to them, and none of their leaves buried in the ground, as from their abounding in moifture, when they are covered with the earth, it is apt to caufe them to rot, which often deftroys the cuttings. When they are taken from the old plants, they fhould therefore be divefted of their lower leaves, fo as to allow a naked ftalk of fufficient length for being planted in the earth.

Thofe in pots may be plunged in a hot-bed, or in a warm border, due fhade and fhelter being given, and flight waterings in dry weather. When they have ftricken good roots, they fhould be removed with balls of earth into other feparate fmall pots of light fandy mould, being placed in a fhady fituation, a very flight watering being given to fettle the earth about them. After they become well rooted, they may be removed, fo as to have more fun; when they may be kept till autumn, being watered very flightly twice a week in fummer and once afterwards, care being taken to prevent their roots fhooting through the pots, by fhifting them two or three times in the fummer feafon in order to pare them off.

In the autumn and winter they fhould be protected in the greenhoufe.

The cuttings of the more fucculent forts fhould be left to heal over a much longer time, being a little freed from leaves, and covered with glaffes to prevent the wet. They fhould have lefs water, and be removed lefs frequently. They fucceed well in an airy glafs cafe during the winter, when fcreened from frofts and fevere weather.

And fuch forts as do not afford cuttings, may be increafed by planting and managing the bottom fide-heads or off-fets in the above manner. They may likewife be increafed by feeds or cuttings readily in the ftove department.

The only culture neceffary afterwards is, merely to give water frequently in fmall quantities in fummer, and very fparingly in winter, fhifting the plants occafionally into larger pots.

Thefe are moftly plants which afford a fine variety in greenhoufe collections, and among other potted plants of fimilar growths.

MESEMMA, or Bousemmo, in *Geography*, a town of Africa, in the kingdom of Fez, inhabited by Arabs.

MESENTERIC, in *Anatomy*, from mefentery, an epithet ufed in defcribing parts connected with the mefentery. There are a fuperior and inferior mefenteric artery, branches of the abdominal aorta (fee Artery): a fuperior and inferior mefenteric vein joining the vena portarum. (See Liver.) The glands connected with the lacteals and with the abforbents of the large inteftine, are called mefenteric, and the fame term is applied to the nerves of the inteftines.

MESENTERICA, in *Botany*, a genus of the fungus tribe, fo called by Tode, from its refemblance to the human mefentery.—Perf. Syn. 706. Tode Fung. Mecklenb. fafc. 1. 7.—Clafs and order, *Cryptogamia Fungi*. Nat. Ord. *Fungi*.

Eff. Ch. Creeping, gelatinous, veiny; the ramifications of the veins joined by a thin membrane.

1. M. *lutea*. Perf. n. 1. (M. tremelloides α, lutea; Tode fafc. 1. 7. t. 2. f. 12.)—Lemon-coloured, or of a golden yellow.—Found after rain in the fpring, fometimes in autumn, upon rotten wood, fpreading to the breadth of two or three inches, like a fine veiny web, of a yellow colour, more or lefs deep; fometimes greenifh. The margin at length fwells, and affumes a bright yellow hue; whence Tode concluded that part to be the feat of the fructification. The whole is fo delicate, that if expofed for twelve hours to a warm air, it decays entirely, leaving nothing but a few very minute fcales.

2. M. *cærulea*. Perf. n. 2. (M. tremelloides β, cærulea; Tode fafc. 1. 8.)—Entirely of a glaucous blue.—Found once only, in September, on a half-rotten board. *Tode*.

3. M. *argentea*. Perf. n. 3. (Corallo-fungus argenteus, omenti formâ; Vaill. Parif. 41. t. 8. f. 1.)—White, very broad; the margin tumid and downy. On old boards or pofts in cellars, fpreading from a little foft and tender tuft, as white as fnow, into a membrane from four to twenty-four inches in extent, full of beautifully branching veins, and fringed at the margin. After fome time, the whole turns reddifh and decays.

MESENTERIUM, Mesentery, in *Anatomy*, the procefs of peritoneum, by which the fmall inteftine is retained in its pofition in the abdomen. See Intestine.

MESERCAN, in *Geography*, a town of Perfia, in Chufiftan; 36 miles S.S.E. of Sufter.

MESERJEEN, a town of Algiers; 5 miles S.W. of Oran.

MESERITSCH, or Meserzicz, a town of Moravia, in the circle of Prerau; 30 miles E. of Olmutz. N. lat. 49° 26′. E. long. 18° 2′.

MESERITSCH, Great, a town of Moravia, in the circle of Iglau; 18 miles W. of Olmutz. N. lat. 49° 23′. E. long. 15° 55′.

MESERITZ, a town of the duchy of Warfaw; 40 miles W. of Pofen.

MESEWITZ, a town of Pruffia, in the palatinate of Culm; 21 miles E.S.E. of Culm.

MESHES *of Nets*, the openings or interftices between the threads.

MESHTA, in *Geography*, a town of Egypt, on the left bank of the Nile; 7 miles N. of Tahta.

MESIANO, the name of two towns of Naples, in Calabria Ultra; one six miles N.E. of Bova, and the other three miles N. of it.

MESINAN, a town of Persia, in the province of Mazanderan; 50 miles S. of Afterabad.

MESIRE, a name given by Avicenna to a distemperature of the liver, attended with a sense of heaviness, tumour, inflammation, and pungent pain, and always with thirst, a dry mouth, and a parched black tongue.

MESITICUM, among the Romans, a toll paid for a place to sell goods in the forum.

MESKOUTEEN, Hammam, *i. e.* the *silent* or *enchanted baths*, celebrated baths of Algiers, in the province of Constantina, situated on a low ground, surrounded with mountains. The water furnished by several fountains is intensely hot, and falls afterwards into the river Ze-nati. Other baths at a small distance are, comparatively, intensely cold; and still farther, nearer the banks of the Ze-nati, are the ruins of a few houses, built probably for the convenience of persons who came thither for the benefit of the waters; 36 miles E. of Constantina. Shaw's Travels.

MESLAY, a town of France, in the department of Mayenne, and chief place of a canton, in the district of Laval. The place contains 1173, and the canton 10,154 inhabitants, on a territory of 245 kiliometres, in 14 communes.

MESLE-sur-Sarthe, a town of France, in the department of the Orne, and chief place of a canton, in the district of Alençon. The place contains 648, and the canton 9364 inhabitants, on a territory of 157½ kiliometres, in 20 communes.

MESLIN-Corn, in *Agriculture*, a term applied to wheat and rye produced in a state of mixture.

MESMARCHURES, in the *Manege*. See Pastern.

MESMES, Claude de, *Count d'Avaux*, in *Biography*, an eminent French negociator, descended from an illustrious family, was trained from an early period of life to public business, and was appointed counsellor of state in the year 1623. In 1627 he was sent as ambassador to Venice, in which quality he visited Rome, Mantua, Florence, and Turin. He next passed into Germany, where he held conferences with most of the princes of the empire. Soon after this he was dispatched upon public business to the more northern kingdoms of Poland, Denmark, and Sweden. In every undertaking he obtained a high character for probity as well as talents, and thus acquired an almost unlimited confidence with the foreign ministers, with whom he treated. This enabled him to act with considerable effect as plenipotentiary, from his court, at the general peace, concluded, in 1648, at Munster and Osnaburg. He did not confine himself wholly to the affairs of the state, but also maintained a regular correspondence with men of letters, of whom he was the friend and protector. He died at Paris in 1650. Moreri.

Mesmes, John Antony de, *Count d'Avaux*, and a nephew of the preceding, passed through a similar course of public employments with his uncle. He was appointed ambassador extraordinary to Venice from 1671 to 1674, and in the following year was one of the plenipotentiaries at the peace of Nimeguen. Some time after this he was ambassador in Holland, where he effected the truce with Spain by which Luxemburgh was ceded to France. In 1689 he was the French ambassador to James II. while in Ireland. In 1692 he went out in the same quality to Sweden, and was very useful in settling the preliminaries of the peace of Ryswick. He died in 1709, at Paris, at the age of sixty-nine, having passed an active and very useful life in the service of his country. A collection of his "Letters and Negociations" was published in 1752, in six volumes 12mo. Moreri.

MESN, or Mesne, a term in *Law*, signifying him who is lord of a manor, and so hath tenants holding of him; yet he himself holds of a superior lord.

All the land in the kingdom is supposed to be holden, mediately or immediately of the king; who is styled the lord "paramount," or above all. Such tenants as held under the king immediately, when they granted out portions of their lands to inferior persons, became also lords with respect to those inferior persons, as they were still tenants with respect to the king; and, thus partaking of a middle nature, were called *mesne*, or middle lords. So that if the king granted a manor to A, and he granted a portion of the land to B, now B was said to hold of A, and A of the king; or, in other words, B held his lands immediately of A, but mediately of the king. The king was therefore styled lord paramount; A was both tenant and lord, or was a mesne lord; and B was called tenant "paravail," or the lowest tenant; being he, who was supposed to make "avail," or profit of the land. It is in this manner all the lands of the kingdom are holden, which are in the hands of subjects. Bl. Com. b. ii.

The word is properly derived from *maisne, quasi minor natu*; because his tenure is derived from another, from whom he holds: or perhaps *mesn* is the same as *mean* or middle between two extremes, either in time or dignity.

Mesn also denotes a writ, which lieth where there is lord mesn and tenant; and lies, when upon a subinfeudation the mesn or middle lord suffers his under-tenant, or tenant paravail, to be distrained upon by the lord paramount, for the rent due to him from the mesne lord. F. N. B. 135.

This is in the nature of a writ of right; and in this case the tenant shall have judgment to be acquitted or indemnified by the mesne lord; and if he makes default therein, or does not appear originally to the tenant's writ, he shall be forejudged of his mesnalty, and the tenant shall hold immediately of the lord paramount himself.

Mesn, or *Mesne process*. See Process.

MESNA, in *Geography*, a city of Africa, capital of Begarmee; 170 miles S. of Bornou. N. lat. 17°. E. long. 22° 12′.

MESNAGER, Nicholas, in *Biography*, an able negociator, was born at Rouen, in 1658, of a rich commercial family. He was sent by Louis XIV. to Spain on some important missions relative to the commerce of the Indies, and afterwards to Holland; on which occasions he gave so much satisfaction as to be created a chevalier of the order of St. Michael, with patents of nobility. In 1711 he signed the preliminary treaty of peace between France and England at London, and he was next employed with the abbé Polignac as plenipotentiary at Utrecht. He died at Paris in 1714. His memoirs have been printed. Moreri.

MESNARDIERE, Hippolytus Julius Pilet de la, a French poet, was born at Loudun in 1610, and died in 1663. He was a member of the French Academy, and patronized by cardinal Richelieu. His works are, 1. "A Treatise on Melancholy," 8vo.; 2. "Poetique," 4to.; 3. "The Tragedies of Alinde and La Pucelle de Orleans;" 4. "A Collection of Poems," &c.; 5. "Relations of War," &c. Moreri.

MESNEVY, or Masnavi, in *Oriental Literature*, is a very celebrated work in the Persian language. The author is Jelal ud Din; Rumi is often added to his name, denoting that he was of Lower Asia. He died in 1262, and was buried in a monastery founded by him in the city of Konyeh (Iconium)

(Iconium) for an order of Dervishes. His work is the most esteemed of that numerous class of writings containing the doctrines of Sufism, (see SUFI,) or emblematical theology, and for several centuries his tomb was visited by his devout countrymen, who consider his works as the effect of inspiration, and inferior only to the Koran. As well as religion and morality, the Mesnevy comprises also history and politics. The following character of it is taken from the last volume of sir William Jones's works. "So extraordinary a book as the Mesnavi was never, perhaps, composed by man. It abounds with beauties and blemishes equally great; with gross obscenity and pure ethics; with exquisite strains of poetry and flat puerilities; with wit and pleasantry mixed with dull jests; with ridicule on all established religions, and a vein of sublime piety. It is like a wild country in a fine climate, overspread with rich flowers and with the odour of beasts. I know of no writer to whom the Maulavi can justly be compared, except Chaucer or Shakspeare." The term Maulavi, here used, is usually applied to this great writer, denoting his literary reputation. Commentaries on his works, and abridgments, translations, and imitations of them, are very numerous in the different dialects of the East. See MYSTICAL *Poetry*.

MESNOI, in *Geography*, an island of Russia, in the straits of Vaigatskoi, N. lat. 70° 4'. E. long. 60° 14'.

MESOCHOROS, μεσοχορος, among the ancients. The mesochori were musicians who presided in concerts, and by beating a desk in a regular manner with their feet, directed the measure of the music. For this purpose in the theatre they wore wooden clogs on their feet, that they might be better heard, which were called by the Greeks *crupezia*.

MESOCHORUS, among the Romans, was also used for a person in public assemblies, appointed to give the signal for acclamation at the proper time, that all might join in it at once.

MESOCOLON, in *Anatomy*, the peritoneum connecting the colon in its situation. See INTESTINE.

MESOCUROS, μεσοκουρος, in *Antiquity*, an actress in tragedies, who had the middle part of her head shaven: but others think that mesocuros signifies a girl or very young woman.

MESODMES, or MESOMEDES, in *Biography*, a Greek lyric poet and musician, to whom the hymn to Nemesis, the last of the three hymns published in Dr. Fell's Oxford edit. of Aratus, with the original music, has been ascribed. It is not satisfactorily settled who this Mesomedes was, or at what time he lived. See MUSIC *of the Ancient Greeks*, for conjectures on the subject.

MESOGASTER, MESOGASTRION, in *Anatomy*, a name sometimes given to the lesser omentum. See EPIPLOON.

MESOGLOSSI, a name given by some writers to the muscles of the tongue, more usually called by anatomists the geniogloffi.

MESOIDE, in the *Greek Music*, a kind of melopœia, the notes of which were confined to the two middle strings of the meson tetrachord.

MESOIDES, mean sounds, or sounds taken in the middle of the system. See MELOPŒIA.

MESOLA, or MEZOLA, in *Geography*, a town of Italy, in the department of the Lower Po, near the coast of the Adriatic, on an island formed by a branch of the Po; 30 miles E.N.E. of Ferrara.

MESOLABE, MESOLABIUM, a mathematical instrument, invented by the ancients for finding two mean proportionals mechanically, which they could not come at geometrically. See PROPORTIONAL. It consists of three parallelograms, moving in groove to certain intersections. Its figure is described by Eutocius, in his commentary on Archimedes.

MESO-LOGARITHM, a term used by Kepler to signify the logarithms of the co-sines and co-tangents; the former of which lord Napier calls *antilogarithms*, and the latter *differentiales*.

These are also called *artificial sines* and *tangents*.

MESON, in the *Ancient Greek Music*, is the name given to the second tetrachord from the bottom, and it was likewise the name by which the four strings of that tetrachord were distinguished: as the first string was called hypate-meson, the second parhypate-meson, the third lichanos-meson, or meson-diatonos, and the fourth mese. Meson is the genitive case plural of mese, mean or middle; because the meson tetrachord is the middle between the first and third tetrachord, or rather because the string or sound mese gives the name to the whole tetrachord, of which it is the highest note. See *Plate of the Greek Diagram*.

MESONYCTICUM, Lat., μεσονυκτικον, Gr., a midnight hymn in the Greek church.

MESO-PLEURII, derived from μεσος, *middle*, and πλευρον, *rib*, in *Anatomy*, the intercostal muscles.

MESO-PLEURII is sometimes also used for the intermediate spaces between the costæ, or ribs.

MESOPOTAMIA, in *Ancient Geography*, an extensive province of Asia, the Greek name of which denotes "between the rivers," and on this account Strabo says, "οἱ κεῖται Μεταξυ τȣ Ευφρατȣ και τȣ Τιγρος," that it was situated between the Euphrates and the Tigris. In Scripture this country is called "Aram," and "Aramæa." But as Aram also signifies Syria, it is denominated "Aram Naharaim," or the Syria of the rivers. This province, which inclines from the S.E. to the N.W., commenced at N. lat. 33° 20', and terminated near N. lat. 37° 30'. Towards the south it extended as far as the bend formed by the Jordan at Cunaxa, and to the wall of Semiramis which separated it from Messene. Towards the north, it comprehended part of Taurus and the Mesius, which lay between the Euphrates and the Tigris. The modern name, given by the Arabs to this part, is of the same import with the ancient appellation; they call it "isle," or in their language, "Al-Dgézera." In this northen part is found Osrhoéne, which seems to have been the same place with Anthemusia. The northern part of Mesopotamia is occupied by chains of mountains passing from N.W. to S.E., in the situation of the rivers. The central parts of these mountains were called "Singaræ montes." The principal rivers were Chaboras (Al Kabour), which commenced at Charræ (Harran), E. of the mountains, and discharged itself into the Euphrates at Circesium (Kirkisieh) (see CHABOR); the Mygdonius (Hanali), the source of which was near Nisibis, and its termination in the Chaboras. (See MYGDONIUS.) The principal towns, in the eastern part along the Tigris and near it, are Nisibis (Nisibin), Bezabde (Zabda), Singora (Sindja), Labbana on the Tigris (Mosul), Hatru (Harder), and Apamea-Mesenes. At some distance to the south, upon the Tigris and on the borders of Mesopotamia, was the town of Antiochia, near which commenced the wall that passed from the Tigris to the Euphrates, under the name of "Murus Mediæ," or "Semiramidis." In the western part were Edessa, called also Callin-Rhæ (Orfa), Charræ (Harran), Nicephorium (Racca), Circesium at the mouth of the Chaboras, Anatho (Anah), Neharda (Hadith Unnour) upon the right of the Euphrates. There are several other towns of less importance, which our limits will not allow us to mention. According to Strabo, this country was fertile in vines,

vines, and afforded abundance of good wine. According to Ptolemy, Mesopotamia had on the north a part of Armenia, on the west the Euphrates, on the side of Syria, on the east the Tigris, on the borders of Assyria, and on the south the Euphrates which joined the Tigris. Mesopotamia was a satrapy under the kings of Syria. See SYRIA.

MESOPYCNI, μεσοπυκνα, in the *Ancient Music*, was an appellation given to such chords as formed the middle notes of the spissa. There were five mesopycni in the scale. See PYCNI and SPISSUM.

MESORECTUM, in *Anatomy*, the process of peritoneum attached to the sigmoid flexure of the colon, and upper part of the rectum. See INTESTINE.

MESORO, in *Ichthyology*, a name given by Salvian to that fish which we call the butterfly-fish, the blennus or blennius of other authors.

MESORO is also used by the Italians for the fish commonly called the *uranoscope*, or *star-gazer*.

MESOTHENAR, in *Anatomy*, a name given by Winslow to a muscle of the thumb. It includes the adductor pollicis, and a part of the flexor brevis. See ADDUCTOR and FLEXOR.

MESOTYPE, in *Mineralogy*. See ZEOLITE.

MESPILEUS LAPIS, in *Natural History*, a name given to some species of the echinitæ, from their resemblance to the ripe fruit of a medlar. This was a name given them before they were much known, and they were some time afterwards called, from their five lines on the surface, *pentexoche*.

MESPILUS, in *Botany*, μεσπιλη of the Greeks, the Medlar-Tree. Linn. Gen. 251. Schreb. 339. Willd. Sp. Pl. v. 2. 1010. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 205. Sm. Fl. Brit. 529. Juss. 335. Lamarck Dict. v. 4. 437. Illustr. t. 436. Michaux Boreal-Amer. v. 1. 291. Gærtn. t. 87. (Cratægus; Linn. Gen. 250. Schreb. 338. Willd. Sp. Pl. v. 2. 1000. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2 v. 3. 200. Juss. 335. Lamarck Illustr. t. 433. Michaux Boreal-Amer. v. 1. 287. —Class and order, *Icosandria Pentagynia*. Sm. Intr. 427. Nat. Ord. *Pomaceæ*, Linn. *Rosaceæ*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, concave, in five deep, spreading, permanent segments. *Cor.* Petals five, roundish, concave, with short claws, inserted into the calyx. *Stam.* Filaments about twenty, awl-shaped, inserted into the calyx, not longer than the corolla; anthers simple, roundish. *Pist.* Germen inferior; styles from two to five, (occasionally solitary,) simple, erect; stigmas capitate. *Peric.* Berry roundish, umbilicated, crowned with the closed calyx, but almost perforated in the centre. *Seeds* equal in number to the styles, bony, gibbous at the outer side, each with two kernels.

Ess. Ch. Calyx five-cleft. Petals five. Berry inferior. Seeds two to five, with two kernels.

Botanists have differed concerning the limits of this genus. The *Cratægus* of Linnæus is distinguished from his *Mespilus* solely by the former having but two styles, and occasionally, on the same tree, some flowers with but one; while the latter has five. *Sorbus* is supposed to differ from both in having three styles and as many seeds. Linnæus was well aware of the close relationship between all the three genera, and hints that there is scarcely any sufficient distinction between them. He adds however that "the leaves in *Sorbus* are usually pinnate, in *Cratægus* angular, in *Mespilus* undivided." This would indeed be a character in the habit too important to be overlooked, but unfortunately it is not founded in fact. *M. tanacetifolia* has not merely angular, but pinnatifid leaves, with the fructification of a perfect *Mespilus*, and is so naturally allied to the Hawthorn, *Cratægus Oxyacantha* of Linnæus, that nothing ought to disjoin them. As to *Sorbus*, the *domestica* is shewn in *Engl. Bot.* v. 5. 350, to be a complete *Pyrus*, both by number and structure of all the parts; nor can the *aucuparia* or the *hybrida* (more properly *pinnatifida*) be separated from it, as the number of their styles and cells is variable, though the coats of the latter are rather more coriaceous than in the *domestica*. Other acknowledged species of *Pyrus* indeed have pinnate or pinnatifid leaves. (See PYRUS.) The writer of the present article therefore sees no reason to abrogate what is settled in the *Flora Britannica*, though Willdenow, not having seen that work till he got as far as *Tetradynamia*, has not adopted this correction; and the authors of the new edition of the *Hortus Kewensis* in general follow him, where they themselves have not particularly studied any subject. Hence five of the fourteen species of *Cratægus* in the last-mentioned work are defined with five styles or five seeds, one with three and another with four; a sufficient evidence of their being *Mespili*, in spite of their more or less angular foliage. It is scarcely necessary to observe that the fruit of these two supposed genera is exactly of the same nature. We now follow Linnæus and Gærtner in calling it a *bacca*, or berry, because it is found most convenient to restrict the term *drupa* to pulpy fruits with a solitary nut.

The number of styles is so ill calculated for a generic distinction in this case, that we cannot take advantage of it even to divide *Mespilus* into any tolerably natural sections. The form of the leaves, whether undivided, lobed, or pinnatifid, might serve better. None of this genus is known to have really pinnated leaves.

The species of *Cratægus* are nineteen in Willdenow, of *Mespilus* six; in all twenty-five. They are all either *trees* or *shrubs*, with very hard wood, often thorny; and they have stalked, alternate, almost always deciduous, *leaves*. Their *flowers* are corymbose, sometimes solitary; white with an occasional tint of red. *Fruit* mealy, red or yellow, seldom eatable. The whole genus is very patient of cold, partly American, partly European and Alpine, well calculated and much used for the adorning of shrubberies in this climate. It is remarkable that none of them have been published in that useful and deservedly popular work, the Botanical Magazine.

We shall indicate a few of the most valuable.

M. *coccinea*. Great American Hawthorn. (Mespilus apii folio virginiana, spinis horrida, fructu amplo coccineo; Pluk. Phyt. t. 46. f. 4. Cratægus coccinea; Linn. Sp. Pl. 682. Willd. n. 1. Ait. n. 1.)—Thorny. Leaves ovate, with angular incisions, serrated, smooth; heart-shaped at the base. Footstalks and calyx glandular. Styles five.—Native of Virginia and Canada. Cultivated by bishop Compton at Fulham in 1683. This is a spreading tree, with broad light green *leaves*, strong thorns, large white copious *flowers*, which appear in May, and scarlet *fruit*, as big as a small damson. Linnæus and Willdenow cite under this, synonyms of Miller (*Ic. t.* 179.) and the *Hort. Angl. t.* 13, which belong to *Mespilus cordata*, their *Cratægus*, n. 2.

M. *parvifolia*. Small-leaved Hawthorn. (M. Xanthocarpus; Linn. Suppl. 254. Cratægus parvifolia; Willd. n. 8. Ait. n. 7.)—Thorny. Leaves somewhat wedge-shaped, crenate, cut. Flowers nearly solitary. Segments of the calyx leafy, cut and serrated, as long as the fruit. Styles five.—Native of Virginia. Cultivated here in the time of bishop Compton. We are indebted to Messrs. Lee and Kennedy for a knowledge of this species, for Willdenow quotes a heap of erroneous synonyms, amongst others the

the *Cratægus tomentoſa*, Linn. Sp. Pl. 682. The preſent ſhrub is remarkable for its ſtout, rigid habit; ſtraight dark *thorns*, often two inches in length; ſmall *leaves*, about an inch long, more or leſs downy; rather large *flowers*, moſtly ſolitary, at the end of each ſhort lateral ſhoot, with a long, leafy, green *calyx*. The *fruit* is ſaid to be pale yellow, dotted with little black warts, and containing five ſeeds.

M. *Oxyacantha*. Common Hawthorn, White-thorn, or May. Gærtn. v. 2. 43. t. 87. Sm. Fl. Brit. 529. (Cratægus Oxyacantha; Linn. Sp. Pl. 683. Fl. Dan. t. 634. Bulliard. t. 333, with the flowers of *Prunus ſpinoſa!* C. monogyna; Jacq. Auſtr. t. 292. Oxyacanthus; Ger. em. 1327.)—Thorny. Leaves obtuſe, deeply three-cleft, ſerrated, ſmooth. Styles one or two.—Native of dry, open, ſtony countries in all parts of Europe, flowering in May or June. In the rich deep ſoil of Marſhland it is particularly luxuriant, and the bloſſoms, uſually white, aſſume there a pink hue. Double and roſe-coloured varieties are often cultivated, as well as one with yellow, not ſcarlet, fruit. This tree is one of the greateſt ornaments of our parks and hedges.

M. *odoratiſſima*. Downy Oriental Hawthorn. Andr. Repoſ. t. 590. (M. tanacetifolia β; Sm. Prod. Fl. Græc. Sibth. v. 1. 342.)—Thorny. Leaves deeply five-cleft, jagged; very downy on both ſides. Styles five.—Native of the Levant. In Greece, and the ſouth-weſtern part of the Crimea. Cultivated by Meſſrs. Lee and Kennedy for ſome years paſt. Rather ſtouter than the Common Hawthorn, and diſtinguiſhed by its very ſoft deep-cut *leaves*, larger highly fragrant *flowers*, and globular ſcarlet *fruit*, as big as a ſmall gooſeberry. Mr. Lambert diſcovered, by Pallas's herbarium, that this is the *Cratægus orientalis* mentioned by that intelligent traveller; ſee the Engliſh edition of his Travels, v. 2. 174. and 181.

M. *tanacetifolia*. Tanſy-leaved Hawthorn. Sm. Exot. Bot. v. 2. 51. t. 85. Ait. Hort. Kew. ed. 2. v. 3. 206. Andr. Repoſ. t. 591. (M. orientalis, tanaceti folio villoſo, magno fructu pentagono e viridi flaveſcente; Tourn. Cor. 44. Voy. v. 2. 171. t. 172.)—Thorny. Leaves obtuſe, pinnatifid, cut; downy on both ſides. Styles five. Bracteas permanent.—Native of all the high mountains of Greece. A very deſirable ſhrub for plantations, on account of its large highly-ſcented corymboſe *flowers*, and yellow *fruit*, which reſembles a ſmall apple, and has the ſcent of one. By culture and grafting, it promiſes to become an acquiſition to our tables. From the deſcription in Dioſcorides of his μεσπιλον, "a ſpinous tree with leaves like hawthorn, fruit like a little apple, ſweet, with three hard ſeeds," this ſhould ſeem, as the number of ſeeds varies, to be the very plant; while his μεσπιλον ἕτερον, from Italy, "a tree like an apple tree, but with ſmaller leaves, and a round eatable fruit, with a broad depreſſion, ſlightly aſtringent, and long in ripening," can only be our common garden *Meſpilus germanica*. Tournefort did not obſerve the thorns of the *M. tanacetifolia*, but he deſcribes the eagerneſs with which his Armenian companions collected and ate the fruit, and he mentions the trees as of the ſize of oaks. He notices alſo our preceding *M. odoratiſſima*, as diſtinguiſhed by its red fruit, varying in ſize, rather acid, and more agreeable than that of the *tanacetifolia*.

M. *Azarolus*. Neapolitan Medlar or Azarole. (M. Aronia veterum; Bauh. Hiſt. v. 1. 67. M. prima; Matth. Valgr. v. 1. 229. M. n. 13; Duham. Arb. v. 2. 16. t. 5. (Cratægus Azarolus; Linn. Sp. Pl. 683. Willd. n. 19. Ait. n. 14. Andr. Repoſ. t. 579.)—Somewhat thorny. Leaves obtuſe, nearly ſmooth, in three or five entire-edged ſegments. Styles two.—Native of Italy, the ſouth of France, and Carniola; rare in our gardens. It is akin to the two laſt, but the *leaves* are ſmoother, entire at the edges, and the *ſtyles* but two; though Scopoli ſays the fruit has five cells, which cauſed him to refer this ſpecies to *Pyrus*. We have no doubt that the number of the *ſtyles* and *cells* is the ſame, and therefore this perhaps affords another example of the variableneſs of that number. The *fruit* is ſaid to be auſtere in flavour, and hence Matthiolus found a difference between his plant and the μεσπιλον of Dioſcorides, which, as they had never ſeen the true one, he, and other botaniſts of his time, took this to be; nor were they very wide of the mark. When cultivated, the Azarole is ſpoken of as an agreeable fruit. We have never heard of its ripening in England, nor does the tree often bloſſom.—The old wooden cut of Matthiolus, uſed again by Duhamel, is by far the beſt repreſentation of this ſpecies; that in Ger em. 1454 is more like the *Oxyacantha*.

M. *germanica*. Common, or Dutch Medlar. Linn. Sp. Pl. 684. Willd. n. 1. Ait. n. 1. Engl. Bot. t. 1523. Pallas Roſſ. v. 1. p. 1. 29. t. 13. f. 1. (M. altera; Matth. Valgr. v. 1. 230. M. ſativa; Ger. em. 1453.)—Thorns none. Leaves lanceolate, ſomewhat downy. Flowers ſolitary, ſeſſile, terminal. Styles five.—Native of the warmer parts of Europe. Common in gardens, for the ſake of its fruit, which is not eatable till it becomes quite mellow, and is almoſt as variable in ſize and flavour as any other. The *leaves* are a ſpan long, moſt downy beneath, dark green above, a little ſerrated at the top. *Flowers* the largeſt of the genus, white, as broad as a crown piece. *Fruit* broad, depreſſed, brown when ripe.

M. *grandiflora*. Large-flowered Barren Medlar. Sm. Exot. Bot. v. 1. 33. t. 18. Ait. n. 5.—Thorns none. Leaves elliptic-oblong, ſlightly downy, unequally ſerrated. *Flowers* nearly ſolitary, terminal. Styles three.—Cultivated in Chelſea garden by Mr. J. Fairbairn, who is unacquainted with its native country. The *tree* much reſembles the *M. germanica*, but the *leaves* are ſtrongly ſerrated, and more elliptical. *Flowers* white, ſcentleſs, almoſt as big as thoſe of the *germanica*, and much exceeding thoſe of all the other ſpecies, *tanacetifolia* approaching them moſt nearly in this reſpect. They grow moſtly ſolitary, rarely two together, at the ends of ſmall lateral branches. *Styles* never more than three; often but two. *Fruit* ſmall, reddiſh, with little pulp, rarely perfected in England.

M. *japonica*. Japan Medlar, or Loquat. Thunb. Jap. 206. Willd. n. 2. Ait. n. 2. Banks. Ic. Kæmpf. t. 18. Vent. Malmaiſ. t. 19. (Bywa; Kæmpf. Amœn. 800.)—Leaves obovate, acute, ſerrated; downy beneath. Cluſters aggregate, terminal. Styles five.—Native of Japan; hardy with us, flowering in ſpring and autumn, and often ripening its *fruit*, which is globular, an inch in diameter, yellow, not bad eating. Thunberg ſays this is a very large tree in its native country. The *leaves* are rigid, a foot long, evergreen, ſmooth, and ſhining on the upper ſide, white or ruſty beneath. *Flowers* very numerous, white, on ruſty ſtalks.—This plant remained for ſome time in our ſtoves without flowering, and was taken for a *Volkameria*.

MESPILUS, in *Gardening*, comprehends plants of the deciduous tree flowering ſhrubby and evergreen kinds, of which the ſpecies cultivated are; the Dutch or common medlar (M. germanica); the arbutus-leaved meſpilus (M. arbutifolia); the alpine meſpilus (M. amelanchier); the baſtard quince, or meſpilus (M. chamæ-meſpilus); the ſnowy meſpilus (M. canadenſis); the dwarf meſpilus (M. cotoneaſter); the quince-leaved meſpilus (M. tomentoſa); and the evergreen thorn or meſpilus (M. pyracantha).

In the firſt ſort it is obſerved, that the wild tree differs from the cultivated one in having more ſlender, ſtrigoſe, thorny branches, and much fmaller leaves, flowers, and fruits.

And there are two varieties, the narrow-leaved and the broad-leaved; the firft growing to a large tree, rifing with a ftraighter ftem, and the branches growing more upright than thofe of the Dutch medlar: the leaves are narrower and not ferrate, the flowers fmaller, and the fruit fhaped like a pear. This is a native of Sicily.

The latter never rifes with an upright trunk, but fends out crooked deformed branches at a fmall height from the ground, the leaves are very large, entire, and downy on their under fide: the flowers very large, as alfo the fruit, which is rounder, and approaches nearer to the fhape of an apple: this, bearing the largeft fruit, is now generally cultivated; but there is one with fmaller fruit, called the Nottingham medlar, of a much quicker and more poignant tafte. There are alfo other varieties in the fruit, which are now little attended to by the cultivators of this fruit.

The fecond fpecies varies with red, with black, and with white fruit.

Method of Culture.—They are all eafily raifed by feeds, layers, grafting and budding; but it is the beft practice to raife the medlar kinds principally by grafting or budding, in order to continue the forts.

When they are raifed in the firft method, the feeds fhould be fown in autumn, in a bed of common earth, as they ufually lie a year, or more, before they germinate, as in the haw and holly-berries, &c.

As foon as the plants appear they fhould be watered frequently in dry weather; and in the autumn or fpring following, the largeft be thinned out and planted in nurfery rows, two feet by one afunder; and in another year all the reft may be fet out in the fame manner; and in three or four years they will be proper for being planted out in the garden or fhrubbery grounds.

But in the fecond mode the young branches fhould be laid down in the autumn in the common method; and they will be properly rooted by the autumn following, when they fhould be planted out in nurfery-rows in the fame way as the feedlings.

And the two laft methods fhould be performed on the ftems or ftalks of the larger medlar kinds, or fometimes upon thofe of the white thorn, raifed from feed as above; but the pear-ftock is to be preferred for the common medlars, when intended as fruit trees. The operations are performed in the ufual way, low in the ftocks to form dwarfs; and for half or full ftandards, training the firft fhoot for a ftem, or the ftock may be let form a ftem, and then be wrought at from about three or four to five or fix feet in height. See BUDDING and GRAFTING.

Thofe plants intended for fruit-trees, whether dwarfs, half or full ftandards, in training, fhould, for dwarfs, have the firft fhoots from the graft or bud headed down fhort in fpring, if neceffary, in order to force out a proper fupply of bottom branches, which muft be trained as other dwarf fruit-trees, either for ftandard-dwarfs or efpaliers. When for half or full ftandards, and wrought low in the ftocks, the firft fhoot of each fhould be trained for a ftem, topping it afterwards at the proper height to force out lateral fhoots to form the head; but when wrought high in the ftock, the firft fhoots may either be fhortened or fuffered to grow, as may feem moft proper, according to the natural difpofition of the leading fhoot, in refpect to its furnifhing lateral branches. After this training for the firft year or two, to give the trees their firft proper formation, there fhould not be any further general fhortening of the branches, practifing it only occafionally to particular fhoots, to procure more wood, when neceffary, to fill vacancies, to reduce any irregular growth, or to cut off dead parts. But in other refpects the branches fhould be principally left at full length, and the ftandards left to affume nearly their own natural way of branching. See PRUNING and TRAINING.

Thefe plants are all hardy, fucceeding in any common foil and fituation.

It may be noticed that the firft fort and varieties are cultivated as fruit trees, principally as ftandards, but fometimes as efpaliers for variety; and are often introduced into the fhrubbery plantations. All the other fpecies are proper for ornament in fhrubbery or other plantations, where they effect a fine variety by their different foliage and flowers, as well as their fruit in autumn and winter, which remains long on the branches. They fhould be difpofed—the deciduous kinds principally in affemblage with others of that fort, and the ever-green kind alfo chiefly with thofe of their own kind, arranging each fort according to its height of growth; but the laft fort, being agreeably ornamental, both as an ever-green and in its numerous clufters of fine red berries in winter, fhould have a confpicuous fituation. From its being of a rather flender growth, it is however commonly trained againft walls or the fronts of houfes, for the fupport of its flexible branches, as well as to exhibit its berries more ornamentally. It may however be trained as a ftandard fhrub, like the other forts, in the open fhrubbery; in which cafe it fhould be generally trained with fhort fingle ftems, and be permitted to branch out upwards into fpreading heads, which have a good effect.

MESS, in *Sea Language*, denotes a particular company of the officers or crew of a fhip, who eat, drink, and affociate together, whence *mefs-mate*, denoting one of thefe with refpect to another.

MESS, in *Military Language*. The principal military mefs in Great Britain is kept, and provided for in the extraordinaries of the army, at the Horfe-guards. This mefs confifts of the field officers in waiting, of the life and foot guards, officers in the king's life and foot guards; officer of the queen's guard and tilt picket, and adjutant of the battalion of foot guards that mounts. The colonel of the foot guards is allowed to invite three vifitors. Two breakfafts are likewife provided every morning, one for the guard coming on, and one for the guard going off, together with a fupper every night.

MESSA, in *Geography*, a town of Morocco, fituated on the river Sus, not far from the foot of the Atlas. It is large, divided into three parts, and furrounded with walls. In its vicinity is a mofque, containing the bones of a whale, which the fuperftitious inhabitants confider as thofe of the whale which fwallowed Jonah; 165 miles S.W. of Morocco. N. lat. 29° 56′.

MESSA, *Meffe*, plural. Ital.; *Meffe*, *Meffes*, plu. Fr., the title given in the Romifh liturgy to the high mafs in mufic, confifting of the *Kyrie*, *Chrifte*, *Credo*, *Sanctus*, and *Agnus Dei*. Thefe portions of the church fervice have been fet in the ftyle of our cathedral fervices by every great compofer in Catholic countries, ever fince the laws of counterpoint were fettled, that is, from the latter end of the 15th century to the prefent time. For common occafions the mafs is fet for the choral eftablifhment, accompanied only by the organ: in thefe, folo verfes are feldom introduced; but for feftivals, in Italy, the compofition is more elaborate and fecular, when an additional band and fingers of the firft clafs are employed. Aleffandro Scarlatti, Leo, Pergolefi, Durante, Perez, Jomelli, Sacchini, &c. have compofed maffes, which will be regarded by true judges of compofition as mafter-pieces of the art.

Messa *Bassa*, silent mass whispered by the priest during a musical performance.

Messe *de Capella*, in the *Italian Music*, is used for masses sung by their grand chorus. In these, various fugues, double counterpoints, and other ornaments are used.

Messe *Concertati*, masses wherein the parts reciting are intermixed with chorusses.

MESSALA, M. Valerius Corvinus, in *Biography*, an illustrious Roman, of an ancient and noble family, who distinguished himself in youth by his eloquence and patriotism, and joined the republican army under Brutus and Cassius against the triumvirs. He is described in very high terms by Cicero, in a letter to Brutus, as being almost, or altogether unequalled for integrity, constancy, and the affection which he displayed for the commonwealth. Of his eloquence, Quintilian says, it is splendid, fair, and bearing the stamp of his nobility. At the battle of Philippi he had a distinguished command, and with his legion was the first that turned the left wing commanded by Octavianus Cæsar. After the death of the two republican chiefs, he made his peace with the victor, and, according to one of the historians of Rome, there was no circumstance of the victory more pleasing to Cæsar than the preservation of Messala, nor did any man ever give proof of greater attachment and gratitude than Messala towards Cæsar. Yet, to his honour, it is asserted, that he never, and on no occasion, was backward in shewing his regard to the memory of his earlier friends, and his decided preference of their cause. When he recommended Strato to Cæsar, he said, with tears flowing from his eyes, "this, sir, is the man who performed the last kind office for my beloved friend Brutus;" and at another time, when Cæsar reminded him that he had been no less zealous for him at Actium, than *against* him at Philippi, he answered, "I always espoused the most just side of every question." In the year 31 B.C. he was the emperor's colleague in the consulate, and was sent as his legate into Asia a year or two afterwards. In 37 he obtained a triumph over the Aquitanians; after this, he for a short time held the office of prefect, which he resigned, finding it ill adapted to his habits. He was addicted to literary pursuits, and was a patron of literary persons, particularly of Tibullus, who commemorates him in his elegies, and has left an express panegyric upon him. In old age he composed a work "De Familiis Romanis," cited by Pliny. At the age of seventy, about two years prior to his decease, the faculties of his mind underwent a total decay, and his memory so completely failed him, that he forgot his own name. Plutarch.

MESSALIANS. See Euchites.

MESSALINA, Valeria, in *Biography*, a daughter of Messala Barbatus, married the emperor Claudius, and disgraced herself by her cruelties and scandalous incontinence. Her husband's palace was not the only seat of her lasciviousness, but she even prostituted herself in the most public manner. Her extravagancies at last irritated Claudius so much, that he was obliged to summon her to answer to all the accusations which were brought against her, upon which she attempted to destroy herself, and when her courage failed, one of the tribunes dispatched her with his sword in the year 48. The satirist, in speaking of her, says,

"Et lassata viris, necdum satiata, recessit."

There was another person of this name called also Statilia, who was descended of a consular family, and married the consul Atticus Vistinus, whom Nero murdered. She received with tokens of tenderness her husband's murderer, and married him. She had married four husbands before she came to the imperial throne; and after the death of Nero retired to literary pursuits and peaceful occupations. Otho, after this, paid his addresses to her, but before the consummation of marriage he destroyed himself. In his dying moments he wrote her a pathetic and very consolatory letter.

MESSANA, in *Ancient Geography*. See Messina.

MESSAPIA, a country of Italy, which, though scantily watered, was covered with trees and pastures. Its principal towns were Brundusium, Rudiæ, Lupiæ, Hydruntum, Callipolis, and Tarentum. It was also called Iapygia.

MESSAR, in *Geography*, a small island in the Red sea, N. lat. 17° 26′.

MESSARA, a province of the island of Crete, which lies south to that of Candia, and which is the most fertile, and the most agreeable of the island; it has, among others, a very beautiful plain, six leagues in extent, in which are found an abundance of wheat, barley, flax, cotton, and a variety of fruits. It is crossed by a small river called at this day "Malognithi," and formerly known by the name of "Lethe." It passes by the side of the ruins of Gortyna, and empties itself into the sea facing the Paximadi islands. The wheat of Messara yields a great quantity of flour, which makes excellent bread; it is conveyed on the backs of asses to Candia, Retimo, and Canea; while the inhabitants themselves live all the year on a very coarse barley bread. Messara is reckoned the granary of Crete: its wheat is one of the best in Turkey. The Turks are here more numerous than the Greeks.

MESSASAGUES, or Missasagas, a tribe of Indians in America, on a river of this name, which discharges itself into the N.W. part of lake Huron. This tribe, a few years ago, numbered 500 warriors, but now 80.

MES-SEELAH, a town of Africa, in the kingdom of Algiers; 80 miles S.S.E. of Dellys.

MESSEGNA, a town of Naples, in Otranto; 21 miles N.W. of Lecce.

MESSENE, Maura-Mathi, a town of European Turkey, in the Morea, on a river which runs into the gulf of Coron; 30 miles N.W. of Misitra. This was the ancient Messene or Mycene, the capital of Messenia, N. of Æchalia and S. of Ithome. It was founded by Epaminondas, and peopled about the year 369 B.C. It was a large and magnificent town, embellished by the temples of Neptune, Venus, Ceres, Lucina, &c. by a variety of statues, &c. Strabo represents it as one of the strongest places among the ancients, and compares it with Corinth, being defended by a fortress built on mount Ithome, as the latter city was by a double citadel. On the path which led to this citadel was a fountain called Clepsydra, signifying concealed water. It was pretended, that the nymphs which reared Jupiter came to bathe secretly in this fountain, whence it derived its name. N. lat. 37° 15′. E. long. 21°.

Messene, a kind of island, formed by the Euphrates on the W. and the Tigris on the E. It had, to the north, the wall of Semiramis, and to the south a canal, which separated it from Babylonia, and the Seleucide territory.

MESSENGERS, in the *English Polity*, are carriers of letters and messages; or, more particularly, certain officers, chiefly employed under the direction of the secretaries of state, and always in readiness to be sent with all manner of dispatches, foreign and domestic.

They are always employed with the secretaries warrants to take up persons for high treason, or other offences against the state, which do not so properly fall under the cognizance of the common law; and, perhaps, are not properly to be divulged in the ordinary course of justice. The prisoners they apprehend are usually kept at their own houses, for each

each of whom they are allowed by the government a compenſation. Although it is the conſtant practice to make commitments to meſſengers, it is ſaid that it ſhall be intended only in order to the carrying of offenders to gaol. (1 Salk. 347. 4 Hawk. P. C. c. 16. § 9.) An offender may be committed to a meſſenger, in order to be examined before he is committed to priſon; and though ſuch commitment to a meſſenger is irregular, it is not void. (Skin. 599.) When they are diſpatched abroad, they have an allowance for their journey.

MESSENGERS *of the Exchequer*, are officers attending the exchequer, in the nature of purſuivants; their buſineſs is to attend the chancellor and auditor, &c. and to carry their letters, precepts, &c.

MESSENGER *of the Preſs*, a perſon, who, by order of the court, ſearches printing-houſes, bookſellers' ſhops, &c. in order to diſcover ſeditious books, &c.

There are alſo other officers diſtinguiſhed by this appellation; as the meſſenger of the lord chancellor, of the privy council, of the great wardrobe, the two meſſengers of the yeomen of the guards, meſſenger to the gentlemen penſioners, four meſſengers to the board of commiſſioners for India, meſſenger of the board of longitude, nine meſſengers of the navy pay-office, four meſſengers of the victualling office, meſſenger of the war-office, three meſſengers of the army pay-office, meſſengers of the ordnance-office, meſſengers of the office for auditing the public accompts, meſſengers of the cuſtom-houſe, of the ſtamp-office, of the general poſt-office, ſeven meſſengers to the commiſſioners of bankruptcy, &c.

MESSENGER, in *Mechanics*, the endleſs rope employed in the *capſtan;* which ſee.

MESSENIA, in *Ancient Geography*, a country of Greece, which occupied the S.E. part of the Peloponneſus; it was 13 or 14 leagues in its largeſt dimenſion, and 10 from S. to N. It was bounded, on the north, by the Elide and Arcadia; on the E. by Laconia, on the S. in great meaſure by the Meſſenian gulf, and on the W. by a part of the Ionian ſea. This country was mountainous and unfertile: its principal river was the Pamiſſus, and Meſſene was its capital. It is ſaid by Pauſanias to have derived its name from a princeſs, called Meſſéne, a native of Argos, daughter of Triopas, and granddaughter of Phorbes. She married Polycaon, the youngeſt ſon of Lelex, and perſuaded her huſband to take poſſeſſion of a country ſituated to the W. of Laconia, and inhabited by a ſavage race. Having done this, he gave to the country the name of his wife, and built in it many towns. When the family of Polycaon became extinct; it paſſed under the dominion of ſeveral ſucceſſive ſovereigns; till at length, after the battle of Leuctra, Epaminondas recalled the deſcendants of the Meſſenians, and built Meſſene.

MESSERAG, in *Geography*, a town of the duchy of Courland; 38 miles E. of Goldingen.

MESSEROF, a town of Poland, in the palatinate of Braclaw; 40 miles N.W. of Braclaw.

MESSERSBURG, a poſt-town in Franklin county, Pennſylvania; 168 miles W. by S. from Philadelphia.

MESSERSCHMIDIA, in *Botany*, received its name from Linnæus, in honour of Daniel Theophilus Meſſerſchmid, a German botaniſt who was ſent out by the Ruſſian government to explore the natural hiſtory of Siberia, prior to the expedition under Pallas. He was born in the year 1685, and died about the age of 30. His reſearches were never publiſhed, and he is only known as an author, by a paper which he left, giving an account of the "*Camelus Bactrianus, binis in dorſo tuberibus.*" This was edited by John Amman, and publiſhed in the 14th vol. of the Tranſactions of the Peterſburg Academy. Linn. Mant. 5. Schreb. 103. Willd. Sp. Pl. v. 1. 789. Mart Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 1. 303. Juſſ. Gen. 129. Lamarck Illuſtr. t. 95. Gærtn. t. 109.—Claſs and order, *Pentandria Monogynia.* Nat. Ord. *Aſperifoliæ*, Linn. *Boragineæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, erect, permanent, deeply cloven into five, ſomewhat linear ſegments. *Cor.* of one petal, funnel-ſhaped, tube cylindrical, of a rude texture, longer than the calyx, globoſe at the baſe; limb five-cleft, folded, membranous at the ſides; throat naked. *Stam.* Filaments five, minute, in the lower part of the tube; anthers awl-ſhaped, erect, within the middle of the tube. *Piſt.* Germen ſuperior, nearly ovate; ſtyle cylindrical, very ſhort, permanent, ſtigma capitate, ovate. *Peric.* Berry dry, corky, of a roundiſh cylindrical form, abrupt at the ſummit, which is ſurrounded with four, obtuſe teeth; when ripe it ſeparates into two parts. *Seeds* two in each diviſion of the berry, oblong, bony, incurved, rounded on the outſide, angular within.

Eſſ. Ch. Corolla funnel-ſhaped, with a naked throat. Berry corky, diviſible into two parts, with two ſeeds in each.

1. M. *fruticoſa.* Linn. Suppl. 132. Syſt. Veg. ed. 14. 190.—Stem ſhrubby. Leaves on ſtalks. Corolla ſalver-ſhaped.—A native of the Canary iſlands, eſpecially in the northern parts of Teneriffe, where it was found by Mr. Francis Maſſon, who introduced it into Kew gardens in 1779, where it flowers from June to October.—The *ſtem* of this ſhrub is lofty, rugged, rough with hairs, branched; branches panicled at the top. *Leaves* alternate, on long ſtalks, lanceolate, entire, veined, hairy. *Spikes* of flowers compound, directed one way, forked, at the ends of the twigs on the upper part of the ſtem. Linnæus obſerves that this ſpecies has the corolla of *Tournefortia,* to which the genus is nearly allied, but its fruit is that of a *Meſſerſchmidia.* It is very ſimilar to the following ſpecies *M. Arguzia,* differing only in its ſhrubby ſtem, ſtalked leaves, ſhorter calyx, and ſmaller, ſalver-ſhaped corolla, with a flat limb.

Profeſſor Martyn has quoted a figure of this ſpecies as being in the ſecond volume of *L'Heritier's Stirpes Novæ*, on the authority of the editor of the firſt edition of *Hortus Kewenſis;* and we know that this quotation, in the latter work, aroſe from a communication of L'Heritier to Mr. Dryander. The ſecond volume however of *Stirpes Novæ* never appeared, and therefore Mr. Dryander repented of having quoted it, determining never to refer to an unpubliſhed figure again; accordingly the reference is ſuppreſſed in the ſecond edition of *Hortus Kewenſis.*

2. M. *Arguzia.* Linn. Mant. 42. Suppl. 132. (Meſſerſchmidia; Hort. Upſ. 36. Gmel. Sib. v. 4. 77. Arguzia; Amman. Ruth. 29. Tournefortia ſibirica; Linn. Sp. Pl. 202.)—Stem herbaceous. Leaves ſeſſile. Corolla funnel-ſhaped. A native of dry, gravelly, ſunny places in Siberia. *Root* creeping. *Stem* erect, three or four inches high. *Branches* alternate, ſterile. *Leaves* alternate, ſeſſile, ovate-oblong, veined, downy, whitiſh. *Corymbs* or *tufts* of flowers frequently two. *Calyx* ſhorter than the tube of the *corolla,* which is white, larger than in the preceding, with the throat naked and pervious; the limb plaited and its ſides membranous.

3. M. *cancellata.* Willd. n. 3. D'Aſſo. Synop. n. 162. t. 1. f. 2. (Cerinthe foliis lanceolatis, caulibus ramoſis, floribus vix calycem ſuperantibus, fructibus cancellatis; Quer. Hiſp. v. 4. 145. t. 25.)—Leaves ſeſſile, linear, obtuſe, hiſpid. Capſules reticulated.—A native of Spain.—We adopt this

this on the authority of Willdenow, without being able to conſult his references. " *Plant* a foot high. *Root* fibrous, reddiſh. *Stems* hairy, branched. *Radical-leaves* lanceolate, rather obtuſe, hiſpid, thoſe of the ſtem ſimilar, but narrower. *Flowers* on ſtalks, in cluſters, of a blue colour."—D'Aſſo obſerves that one *ſeed* in each diviſion of the berry is abortive.

MESSI, in *Geography*, a town of Aſiatic Turkey, in Natolia, built on the ſcite of *Halicarnaſſus*, which ſee; 50 miles S.W. of Mogla. N. lat. 37° 46′. E. long. 27° 22′.

MESSIAH, a term ſignifying *anointed*, or *ſacred;* and, in that ſenſe, applied to kings and prieſts; but, particularly, by way of eminence, to Jeſus Chriſt, the ſaviour promiſed by the prophets of the old Jewiſh law.

The word comes from the Hebrew מָשׁוּחַ, *maſcuach*, *anointed*, of the verb מָשַׁח, *maſchach, to anoint;* whence Jeſus Chriſt claims the title on a manifold account; 1, as having been anointed king of kings from all ages; 2, as chief of the prophets; 3, as high prieſt of the law of grace, or prieſt for ever after the order of Melchizedech.

The prophecies in the Old Teſtament, which relate to the coming of the Meſſiah, are very numerous; ſome of which may be found in Gen. iii. 15. xlix. 10. Iſaiah, vii. 14. c. xi. c. lii. liii. which the Targum of Jonathan interprets of the Meſſiah. Dan. ix. 25. Micah, iv. 1—5. c. v. 2—4. Haggai, ii. 6, 9. Zech. iii. 8—10. vi. 12, 13. ix. 9—12. Mal. iii. 1—4. iv. 2—6, &c.

It has been alſo urged, that there are ſome remarkable paſſages in Joſephus, Philo, Tacitus, Suetonius, and Celſus, which ſhew that the expectation of the Meſſiah, agreeable to the ſcripture prophecies, prevailed in ſome degree among the heathen nations; and many have ſuppoſed that there is ſome reference of this kind in the fourth eclogue of Virgil. We ſhall only add farther, that the beſt Chriſtian writers lay little ſtreſs on the prophecy of Chriſt cited by Abulpharagius, out of the books of Zerduſh or Zoroaſter, nor on the pretended prophecy of Confucius, among the Chineſe; nor on thoſe of the Sibylline oracles, among the Romans.

The Jews ſtill wait for the coming of the Meſſiah, being infatuated with the notion of a temporal Meſſiah, that is to be a mighty conqueror, and to ſubdue all the world. Moſt of the modern rabbins, according to Buxtorf, believe that the Meſſiah is already come, but that he keeps himſelf concealed, and will not manifeſt himſelf becauſe of the ſins of the Jews. Some of the Jews, however, in order to reconcile thoſe prophecies that ſeem to contradict each other, as to the character and condition of the Meſſiah, have had recourſe to the hypotheſis of two Meſſiahs, who are yet to ſucceed each other; one in a ſtate of humiliation and ſuffering; the other of glory, ſplendor, and power. The firſt, they ſay, is to proceed from the tribe of Ephraim, who is to fight againſt Gog, and to be ſlain by Annillus, Zech. xii. 10. The ſecond is to be of the tribe of Judah, and lineage of David, who is to conquer and kill Annillus, and reſtore the kingdom of Iſrael, reigning over it in the higheſt glory and felicity.

Jeſus Chriſt aſſerts himſelf to be the Meſſiah. In St. John iv. 25. the Samaritan woman ſays to Jeſus, " I know that when the Meſſiah comes, who is called the Chriſt, he will tell us all things. Jeſus anſwered her, I that ſpake to thee am he." There are ſeveral impoſtors, who have endeavoured to paſs for Meſſiahs, as Chriſt himſelf predicted. J. Lent, a Dutchman, has written a hiſtory of *falſe* Meſſiahs, " De Pſeudomeſiis." The firſt he mentions was one Barcochab, who appeared under the empire of Adrian. The laſt was rabbi Mordecai, who began to be talked of in 1682. A little before him; *viz.* in 1666, appeared Sabbethai Sebi, who was taken by the Turks, and turned Mahometan.

MESSIEURS, a French title of honour, or civility, lately introduced into our language; being the plural of *monſieur*, and equivalent to the Engliſh ſirs, or gentlemen.

The French lawyers always begin their pleadings and harangues with meſſieurs; which word is alſo frequently repeated in the courſe of their ſpeeches; on which occaſion it anſwers to our Engliſh word *gentlemen.*

The French ſay, *Meſſieurs du parlement; du conſeil; des comptes*, &c.

MESSILLONES, or MUSCLE-*Bay*, in *Geography*, a bay on the coaſt of Chili or Peru, in South America; 8 leagues N. by E. of Morrenas bay, and 5 S. by W. of Atacama. It forms part of Atacama bay, and at its entrance, or the anchoring place, ſhips may ride in 15 fathoms, clean ground, and ſecured from moſt winds.

MESSINA, a city and ſea-port of Sicily, in the valley of Demona, the ſee of an archbiſhop, ſituated on the E. coaſt towards the narrow ſea, called " The Straits of Meſſina," formerly called " Zancle," which name it received, according to Thucydides, from the form of its harbour, that reſembles a hook. This author ſuppoſes that the city was founded by the pirates of Cuma. Other writers trace its origin to a higher antiquity, and date it 530 years before the ſiege of Troy, and 964 years before Romulus laid the foundation of Rome. They add, that when the inhabitants were moleſted by the pirates of Cuma, they ſought the aſſiſtance of the Meſſenians, a people of Greece, who haſtening to their ſuccour, cleared their coaſts, entered into an alliance with them, and hence the city was called by the Greeks " Meſſene," and by the Latins " Meſſana." Pauſanias ſays, that Anaxilas, tyrant of Rhegium, having formed an alliance with the Meſſenians of Greece againſt the Zancleans, with their aſſiſtance took poſſeſſion of the city, which, in compliment to them, he called " Meſſene." This event is ſaid to have taken place in the year of Rome 94. This city was afterwards ſeized by the Mamertini, and being made their capital, it became one of the moſt wealthy and powerful cities of Sicily. The Mamertini transferred it to the Romans, and from them it was taken, in the firſt Punic war, by the Carthaginians. Under the Romans it enjoyed a long interval of peace, and was ſpared by the rapacious Verres. In the civil wars it took part with Sextus Pompeius. After the fall of the Roman empire it was for ſome time in the poſſeſſion of the Saracens: and, in 1060, was taken by Roger, count of Calabria, who alſo aſſumed the name of the count of Sicily. In 1139, Richard I. king of England, made himſelf maſter of it in his way to the Holy Land. It was afterwards betrayed to Louis XI., king of France, who was compelled to ſurrender it. The harbour of this city has been much admired, and the quay is decorated with a range of buildings, nearly uniform in its whole length, and interrupted only by a number of arches, which ſerve as entrances into the correſponding ſtreets that terminate upon it. At the bottom of the port is the king's palace, the reſidence of the governor of the city, before whoſe door the veſſels of the royal navy lie at anchor. Near this is a covered walk, which leads to the citadel, which is almoſt impregnable, and cannot be attacked by ſea, on account of the currents and the difficulty of anchorage, nor is it overlooked on the land ſide, whilſt it commands the city and harbour. This was built by Charles XI. after a revolt of the inhabitants. There is a communication by a covered way, and a wide ſubterranean paſſage formed under the jettee, between the citadel and two forts;

forts; one that of the Lantern, which points out the channel in the Calabrian coast, and that of St. Salvador, which defends the entrance of the port. It seems as if nature had designed even the whirlpools of Scylla and Charybdis to serve as guards to this superb port; which is capable of containing all the ships of Europe, and where vessels arrive at the very door of the merchant, finding any required depth of water, and needing not to move an anchor, if it were not for the violence of the Sirocco, the only wind to which it is exposed, and by which the ships are in danger of being driven out to sea. In the middle of the haven are a light-house and lazaretto. Within the city are handsome streets, elegant marble fountains, equestrian and pedestrian statues of bronze, large and handsome churches, vast convents, tolerably well built hotels, a magnificent general hospital, called "La Loggia," another large and rich hospital, and near it a well-regulated as well as spacious Lombard house. The population formerly corresponded with these appearances; but the plague of 1743 and 1744 reduced it from 100,000 to 30,000. In 1780 and 1782 it suffered much from an earthquake. The calamities which this city has suffered have not only diminished its population, but occasioned the decay of many houses and the desertion of their occupiers, as well as the decline of their trade, which, however, is still considerable. In August an annual fair is held, at which great quantities of foreign goods are exposed to sale. The air at Messina is temperate, being continually freshened by the sea, purified by the mountains, agitated by the currents, and moderated by the shade and shelter. So that, as De Non says, it is rendered one of the healthiest and most agreeable habitations of the whole world. Messina claims the prerogative of being styled the capital of the kingdom, though Palermo disputes the precedency with it; 104 miles E. of Palermo. N. lat. 38° 10'. E. long. 15° 40'.

MESSINES, a town of France, in the department of the Lys, and chief place of a canton, in the district of Ypres. The place contains 3155, and the canton 17,956 inhabitants, on a territory of 167½ kiliometres, in 8 communes.

MESSING, a town of Bavaria, in the bishopric of Aichstatt; 14 miles N.N.E. of Aichstatt.

MESSIS, a town of Asiatic Turkey, in Caramania; 15 miles E.S.E. of Adana.

MESSUAGE, Messuagium, in *Law*, a dwelling-house, with some land adjoining, assigned for its use.

By the name of messuage may a garden, shop, mill, cottage, chamber, cellar, or the like, pass.

In Scotland, messuage denotes what we call the *manor-house, viz.* the principal dwelling-house within the barony.

MESSUBY, in *Geography*, a town of Sweden, in Tavastland; 34 miles N.W. of Tavasthus.

MESTA, in *Geography*, a town and cape on the W. coast of the island of Scio. N. lat. 38° 25'. E. long. 30° 54'.

Mesta, a Spanish term, which, in its general acceptation, signifies a mixture of two or more sorts of grain, and is equivalent to the English word "Meslin," denotes, in a more restricted sense, the union of the flocks belonging to several different proprietors into one collective body, which does not strictly attach to any country, but travels backward and forward twice in the year, passing part of it at one place, and part in another. This collection is formed by an association of proprietors, consisting of the nobles, persons in power, members of rich monasteries and ecclesiastical chapters, who feed their flocks on the waste lands, as is done on the commons in England. These flocks they call *Merinos*, or *transhumantes*.

This custom, first introduced by circumstantial necessity, in process of time was converted into a claim, which long possession has now changed into a prescriptive right. It rests at present upon the support of those laws and ordinances which have favoured, protected, and perpetuated the usurpation.

The origin of this custom must be referred to the era in which the great plague ravaged Spain, and destroyed two-thirds of the population. The few persons who survived that destructive scourge took possession of the lands which had been vacated by the death of their former occupiers. These they united with their own for the purpose of forming large properties; but not possessing sufficient means for the cultivation of such extensive domains, they were obliged to convert nearly the whole into pasturage, and confine their attention principally to the care and increase of their flocks. Hence has arisen the vast quantity of pasture lands which occupy the greater part of Estramadura, the kingdom of Leon, and other provinces. To this cause, among others, may be attributed the prodigious quantity of uncultivated lands discoverable through the whole kingdom; and hence so many proprietors, who possess extensive tracts of territory, yet have no titles to their estates, and are therefore denominated *Dueñosfvoceros*.

The flocks which, when united, form the Mesta, usually consist of about ten thousand sheep in each. Every flock is conducted by an officer, called a *mayoral*, who superintends the shepherds, and directs the route. It is essential that he should be an active man, well acquainted with the kinds of pasturage, the nature of sheep, and methods of treatment. The mayoral is allowed a horse and one hundred *doublons*, or fifteen hundred livres tournois (thirty pounds eight shillings sterling) *per annum*. Placed under him are fifty shepherds, who are divided into four classes. The wages amount to one hundred and fifty reals, or thirty-seven livres ten sols (one pound eleven shillings and three-pence) *per* month, for the first class; one hundred reals, or twenty-five livres (one pound and eleven-pence) for the second; sixty reals, or fifteen livres (twelve shillings and ten-pence) for the third; and forty reals, or ten livres (eight shillings and four-pence) for the fourth: exclusive of these wages, each is allowed a daily ration of bread, weighing two pounds. They receive individually twelve reals, or three livres (two shillings and sixpence) for travelling expences, when they commence their journey in the month of April or May; and the like sum on their return in October. To each shepherd is granted the privilege also of keeping a few sheep and goats, but the wool and hair belong to the proprietor of the flock; he takes himself the increase, the flesh, and the milk; but he cannot take any part of these away. The number of persons thus employed in the care of the whole of the flocks which compose the Mesta, are about forty-five or fifty thousand. The dogs are also numerous, fifty being the allowance to each flock.

The number of sheep which are thus made to migrate has varied at different periods. It very much decreased during the seventeenth century. It was again increased in the eighteenth. In the sixteenth the enumeration comprised seven millions. At the commencement of the seventeenth, in the reign of Philip III., they were reduced to two millions five hundred thousand. Ustaria states the number in his time, about the end of the same century, at four millions; they amount at present to near five.

The flocks are put in motion the latter end of April, or beginning of May, leaving the plains of Estramadura, Andalusia, the kingdom of Leon, and Old and New Castile, where they usually winter; they repair to the mountains of the

the two latter provinces, and thoſe of Biſcay, Navarre, and Aragon. The mountainous diſtricts moſt frequented by theſe flocks in New Caſtile are thoſe of Cuença; and in Old Caſtile, thoſe of Segovia, Soria, and Buytrago. The ſheep, while feeding on the mountains, have occaſionally adminiſtered to them ſmall quantities of ſalt. It is laid upon flat ſtones, to which the flocks are driven, and permitted to eat what quantity they pleaſe. During the days the ſalt is adminiſtered, the ſheep are not allowed to depaſture on a calcareous ſoil, but are moved to argillaceous lands, where they feed voraciouſly.

At the end of July the ewes are put to the rams, after ſeparation has been made of thoſe already with lamb. Six or ſeven rams are conſidered ſufficient for one hundred ewes.

In September the ſheep are ochred, their backs and loins being rubbed with red ochre, or ruddle, diſſolved in water. This practice is founded upon an ancient cuſtom, the reaſon of which is not clearly aſcertained. Some ſuppoſe, that the ochre uniting with the oleaginous matter of the fleece, forms a kind of varniſh, which defends the animal from the inclemency of the weather. Others think the ponderoſity of this earth prevents the wool growing too thick and long in the ſtaple. But the more eligible opinion is, that the earth abſorbs the ſuperabundant perſpiration, which would otherwiſe render the wool both harſh and coarſe.

Toward the end of the ſame month the flocks recommence their march. Deſcending from the mountains, they travel towards the warmer parts of the country, and again repair to the plains of Leon, Eſtramadura, and Andaluſia. The ſheep are generally conducted to the ſame paſtures they had grazed the preceding year, and where moſt of them had been yeaned: there they are kept during the winter.

Sheep-ſhearing commences the beginning of May, and it is performed while the ſheep are on their ſummer journey, in large buildings called *Eſquileos*. Theſe, which are placed upon the road, are capable of containing forty, fifty, and ſome ſixty thouſand ſheep. They are erected in various places; but the principal are in the environs of Segovia, and the moſt celebrated is that of *Iturviaca*. The ſhearing is preceded by a pompous preparation, conducted in due form, and the interval is conſidered a time of feaſting and recreation. One hundred and twenty-five men are uſually employed for ſhearing a thouſand ewes, and two hundred for a thouſand wethers. Each ſheep affords four kinds of wool, more or leſs fine according to the parts of the animal whence it is taken. The ewes produce the fineſt fleeces, and the wethers the heavieſt: three wether fleeces ordinarily weigh on the average twenty-five pounds; but it will take five ewe fleeces to amount to the ſame weight.

The journey which the flocks make in their peregrinations is regulated by particular laws, and immemorial cuſtoms. The ſheep paſs unmoleſted over the paſtures, belonging to the villages, and the commons which lie in their road, and have a right to feed on them. They are not, however, allowed to paſs over cultivated lands; but the proprietors of ſuch lands are obliged to leave for them a path ninety *varas*, or about forty toiſes (eighty-four yards) in breadth. When they traverſe the commonable paſtures, they ſeldom travel more than two leagues, or five and a half miles a day; but when they walk in cloſe order over the cultivated fields, often more than ſix, or near ſeventeen miles. The whole of their journey is uſually an extent of one hundred and twenty, thirty, or forty leagues, which they perform in thirty or thirty-five days.

The price paid for depaſturing the lands, where they winter, is equally regulated by uſage, and is very low; but it is not in the power of the landed proprietors to make the ſmalleſt advance. The Meſta has its peculiar laws, which were originally made by the parties intereſted, the proprietors of flocks, and received the ſanction of ſeveral ſovereigns of Spain, among whom was Charles I., who approved and confirmed them in the year 1544. A particular tribunal alſo exiſts, under the title of "honrado conſejo de la Meſta," or *the honourable council of the Meſta*. This court, in which one of the council at Caſtile preſides, is compoſed of four judges, denominated "Alcaldes mayores entregadores," each having a fiſcal or exchequer, and an eſcheator or *Alguaſil mayor*. The cognizance of this court ſuperintends the preſervation of the privileges belonging to the Meſta. The judges levy upon the ſhepherds and their flocks pontage, parcage, and other tolls; they ſettle the diſputes and quarrels among the ſhepherds; direct the route the flocks ought to take in their journies to and from the mountains; regulate what occurs on their paſſage; ſettle what reſpects their paſturage; in a word, they adjuſt every concern in which the Meſta can be ſuppoſed intereſted in the ſlighteſt degree. The proprietors of flocks, and even the ſhepherds, poſſeſs, to a certain extent, a power of *committimus*, or commitment, which they very frequently abuſe. They have the improper privilege of citing all kinds of perſons, of whatever age or condition, before the Meſta, under a ſuppoſition, or pretence, that their altercations, or buſineſs, have ſome connection, however diſtant, with the juriſdiction of its court.

The public opinion throughout Spain is decidedly oppoſed to the Meſta, againſt the vexatious circumſtances to which it continually gives riſe, and the conſtant obſtacles it throws in the way of agricultural improvements. In fact, the grievances ariſing from its effects are numerous and ſevere.

1. The number of perſons it employs is very great, forty or fifty thouſand; which are ſo many ſubjects loſt to the ſtate, as to the purpoſes of agriculture and population; and this takes place principally in thoſe provinces where the ſtrength requiſite for the cultivation of the ſoil is moſt deficient.

2. An immenſe extent of highly valuable land is converted into paſturage; and produces comparatively nothing. The conſequence is, that the inhabitants of ſuch places find no employ, nor means of providing for their wants: they are refuſed the neceſſary articles for the ſupport of life, becauſe the lands on which they might be grown do not produce them.

3. The cultivated lands, which lie near the route the flocks take in their journies to and from the mountains, are ſubject to continual treſpaſs, which is committed with impunity; for in vain do the owners of thoſe lands appeal againſt ſuch abuſes and ſolicit indemnity. The damages ſuſtained on theſe occaſions is ſo much greater, owing to the ſeaſons of the year in which the journeyings of the flocks are made. The firſt is when the corn is generally far advanced in its growth; and the ſecond when the vines are loaded with grapes.

4. The commonable paſtures alſo, which are in the line of the route, are equally devaſtated; ſo that the flocks belonging to places in the vicinity can ſcarcely find a bare ſubſiſtence.

5. The flocks which compoſe the Meſta are unprofitable for agricultural purpoſes; for never being folded upon the arable lands, they conſequently contribute nothing towards their fertilization.

6. The directors and ſhepherds are dreaded in every place through which they paſs; for they exerciſe a moſt inſufferable

able despotism, the consequence of the improper privilege they possess of bringing whomsoever they may chuse to insult before the tribunal of the Mesta; whose decisions are almost invariably in favour of its servants.

These grievances have for time immemorial excited the most forcible protestations against them; the general states of the realm have incessantly requested the suppression of the Mesta, and the complaints and addresses of the people have been repeatedly presented at the foot of the throne. For a long series of years all appeals upon the subject were in vain. They at length, however, became so loud and pressing, towards the middle of the eighteenth century, that the government found itself obliged to pay some attention to the subject. A committee was formed to make the requisite inquiry, Whether it were more eligible for public utility to continue, or suppress the Mesta? and, provided the committee should determine on the former measure, what modifications might be proper to adopt for its better regulation. The persons interested were very powerful, and they made sure of evading this wise disposition for remedying the evils of the Mesta. The committee, though permanently established, have done nothing these thirty or forty years. Affairs remain in just the same state, and, as it too frequently happens, the interest of a few individuals still obtains the advantage over the public good. Laborde's View of Spain, vol. iv.

MESTERO, in *Geography*, a cape on the N. coast of Egypt; 10 miles N.E. of Rosetta. N. lat. 31° 25′. E. long. 30° 54′.

MESTI, a town of Austrian Poland, in Galicia; 6 miles E.S.E. of Belcz.

MESTRA, a town in the Trevisan; 8 miles N.W. of Venice.

MESTRE BAY, *Little*, a bay on the N.E. part of Newfoundland island, S. of St. Julian, and N. by W. of the islands Gros and Belle.

MESTREZAT, JOHN, in *Biography*, a celebrated French Protestant minister, was born at Geneva in the year 1592. When he was yet very young he was sent to the academy at Saumur, where he afforded such evidence of his abilities and proficiency, that he was offered a professorship of philosophy when he was only eighteen years of age. He became an eloquent and highly distinguished preacher, and there are said to be no sermons that contain more sublime theology than those which he preached upon the epistle to the Hebrews. He conducted the controversy concerning the authority of the church with forcible reasoning, and completely refuted all the subtilties of father Regourd and cardinal Perron on this subject. He died in 1657, leaving behind him a number of theological works that do honour to his memory: of these the chief are, "A Treatise on the Holy Scriptures, in which is shewn the Certainty and Fulness of Faith, and its Independence on the Authority of the Church;" and "An Exposition on the Epistle to the Hebrews, in a Course of Sermons," making five volumes 8vo. Bayle.

MESTURA, in *Geography*, a town of Africa, in the kingdom of Tunis.

MESUA, in *Botany*, a Linnæan genus, in honour of *Mesue*, the father and son, two celebrated Arabian physicians and botanists, who resided at Damascus, and who flourished in the eighth and ninth centuries. The works of the younger *Mesue*, medical and botanical, were published in folio, with annotations, at Venice, in 1581.—Linn. Gen. 268. Schreb. 471. Willd. Sp. Pl. v. 3. 843. Mart. Mill. Dict. v. 3. Juss. Gen. 258. Lamarck Dict. v. 4. 416.—Class and order, *Monadelphia Polyandria*. Nat. Ord. *Guttiferæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of four, ovate, concave, obtuse, permanent leaves, the two outward, opposite ones smaller. *Cor.* Petals four, abrupt, undulated. *Stam.* Filaments numerous, capillary, the length of the corolla, united at the base into a sort of cup; anthers ovate. *Pist.* Germen superior, roundish; style cylindrical; stigma thickish, concave. *Peric.* Nut roundish, pointed, marked with four, longitudinal, elevated sutures. *Seed* solitary, roundish.

Eff. Ch. Calyx simple, of four leaves. Corolla of four petals. Nut slightly four-sided, single-seeded.

1. M. *ferrea.* Linn. Sp. Pl. 734. Fl. Zeylan. 91. (Naghas; Herm. Zeylan. 7. Nagassarium; Rumph. Amboin. v. 7. 3. t. 2. Bellutta Tsiampakam, sive Castanea rosea indica; Rheed. Malab. v. 3. 63. t. 53.)—A native of the East Indies, and much cultivated, according to Rheede, in Malabar, for the beauty of its flowers, which expand there in July and August. It bears fruit in six years from the nut, and continues to bear during three centuries. The same author subjoins a long account of its medical virtues, and Rumphius says, it is planted in Amboyna, about houses, for the shade it affords, and for the odour of its flowers, which also, when dry, are mixed with other aromatics, such as the white sandal-wood, and used for perfuming ointments.

This *tree* grows to a large size, having a variegated, thick, hard, smooth, much-branched trunk, like that of a lime-tree. *Bark* smooth, brown, aromatic, of a sharp and bitter taste. *Root* fibrous, red, covered with a smooth, yellow bark, bitter, but sweet-smelling. *Leaves* opposite, on short stalks, smooth, thickish; of a shining green on the upper side; glaucous-blue underneath, like the bloom of grapes. *Flowers* in size and shape like those of the Sweet-briar or Eglantine, but with only four white petals. Their smell partakes both of the rose and violet. *Fruit* smooth and greenish, but reddish and wrinkled when ripe, with a rind like that of the chesnut, and three or four kernels within, the shape, size, substance, and taste of chesnuts.—The specific name is taken from the close texture and hardness of the wood.

MESUA, in *Gardening*, comprises a plant of the exotic shrubby kind, for the hot-house of which the species cultivated is the ferreous Indian mesua (M. ferrea.)

Method of Culture.—This plant may be increased by seeds, layers, and cuttings. The seeds should be sown in the spring, in pots of light earth, plunging them in a bark hot-bed in the stove. When the plants have attained some growth, they should be planted in separate pots and be re-plunged in the bark-bed, where they must be kept.

The layers should be made from the young branches, and should be laid down in the autumn or early spring, being taken off when well rooted, and planted in separate pots, having the same management as the others.

The cuttings should be taken from the young branches, and be planted in the summer in pots of light mould, and plunged in the bark-bed. When they have stricken root, they should be removed into separate pots, and be managed as the others.

Plants of this kind afford variety among other stove plants.

MESUA, in *Geography*, a town of Arabia, in the province of Yemen; 40 miles N. of Chamir.

MESUE, in *Biography*, one of the early physicians among the Arabians, was born at Nisabour, in the province of Khorasan, and flourished in the ninth century. He is said to have died in 846, or, according to other accounts, in 865. His father was an apothecary at Nisabour. Mesue was educated in the profession of physic by Gabriel, the son

son of George Backtishua, and through his favour was appointed physician to the hospital of his native city. Although a Christian of the Nestorian sect, he was in great favour with several successive caliphs, being reputed the ablest scholar and physician of his age. When the caliph Haroun al Raschid appointed his son, Almammon, to the viceroyalty of the province of Khorasan, Mesue was nominated his body physician, and was placed by him at the head of a college of learned men, which he instituted there. On his accession to the throne of the caliphs, in the year 813, Almammon brought Mesue to Bagdad, and made him a professor of medicine there, as well as superintendant of the great hospital, which situations he occupied a great number of years. He was also employed, under the auspices of the same caliph, in transferring the science of the Greeks to his own country, by translating their works. Freind is of opinion that Mesue wrote in the Syriac tongue, which prevailed in his native province, long before and after his time; for not only he, but the Backtishuas, are reckoned Syrians by Abulpharagius and Abi Osbaia, though born at Nisabour. He was the author of some works, which are cited by Rhazes and other writers, which appear to have perished: for the works, which are now extant in his name, do not correspond with these citations, nor with the character of them given by Haly Abbas; not to mention, that in these works the writings of Rhazes are quoted, who lived long after his time. Abi Osbaia enumerates thirty-seven books written by Mesue, among which is one upon purging, and another respecting decoctions. Freind's Hist. of Physic, vol. ii.

Mesue, *the Younger*. A writer of this name, or *Mesuach*, who was later than Rhazes, and a Christian of the sect of Jacobites, is mentioned by Leo Africanus. He studied medicine and philosophy at Bagdad, and practised at Cairo, where he died in the year 1015, at the age of 90. He wrote some treatises on potable liquors, and on the composition of medicines: and perhaps to him may be attributed the work entitled, "Joannis Mesue Damasceni de Re Medica, lib. iii." edited by Jac. Sylvius, Paris, 1549, folio, and often reprinted. Eloy Dict. Hist. de la Med. Gen. Biog.

MESURACA, in *Geography*, a town of Naples, in Calabria Citra; 8 miles S.W. of St. Severina.

MESURADA, a sea-port town of Africa, in the country of Tripoli, and residence of a governor: a considerable commerce is carried on at this place by means of the caravans that pass into the interior parts of Africa. This is the chief place of a district anciently called "Cyrenaica" and "Pentapolis," from its five cities; 100 miles E.S.E. of Tripoli. N. lat. 32° 10′. E. long. 15° 10′.

MESURADO, a river of Africa, which runs from the mountains that separate Negroland from Guinea, into the Atlantic, N. lat. 6° 25′. W. long. 10° 35′.

MESURE, Fr.; *Misura*, Ital.; measure, in *Music*. In poetry measure is expressed by *metre*; in music, by *time*. See Measure, Metre, and Time.

MESVRES, in *Geography*, a town of France, in the department of the Sâone and Loire, and chief place of a canton, in the district of Autun; 5 miles S. of Autun. The place contains 608, and the canton 6277 inhabitants, on a territory of 302½ kiliometres, in 12 communes.

MESYMNIUM, a name which the ancients gave to a part of their tragedy, or to certain verses in their tragedies.

The mesymnium was a kind of burden, as *Io Pæan; O Dithyrambe; Hymen, O Hymenæe;* or the like; which, when placed at the end of a strophe, was called *ephymnium;* and when inserted in the middle of a strophe, *mesymnium*. See Strophe, and Chorus.

MET, in *Rural Economy*, a term applied to a measure which contains a strike, or four pecks.

META, in *Geography*, a river of South America, which, after receiving several tributary streams, runs into the Oronoko; 30 leagues below the cataracts of Aturas, and 125 leagues from St. Thomas of Guiana. This river, says Depons, seems destined by nature to form vast commercial relations between the whole eastern part of the kingdom of Santa Fé and Spanish Guiana.

METAC, a town of Upper Siam; 130 miles N.W. of Porselouc.

METACAL, an Egyptian weight, used in the weighing of pearls, and consisting either of a carat and a half, or of two carats. Sixteen of these carats make a drachm, each of the carats weighing four grains, and twelve drachms an ounce.

METACARPIUS, in *Anatomy*, the name given by Winslow to the adductor ossis metacarpi digiti minimi; which see.

METACARPUS, one of the divisions of the bones of the hand, placed between the wrist and the fingers. See Extremities.

Metacarpus, *Fracture of*, in *Surgery*. See Fracture.

METACHORESIS, a word used by Galen, to express a recess of a morbid humour from one part of the body to another, a thing very common in many distempers.

METACHRONISM, formed of μετα and χρονος, *time*, in *Chronology*, an error in computation of time, either on the side of defect or excess.

METACINEMA, from μετα, and κινεω, *to remove*, in *Surgery*, a removal of the pupil of the eye from its natural situation.

METACISM, Metacismus, in *Grammar*, a defect in the pronunciation of the letter M.

Isidore represents the metacism as a final *m*, followed by a vowel, as *bonum aurum*, *Bethlehem erat*, &c.

METACOE, in *Botany*, a name given by the people of Guinea to a plant, of which they are very fond, because of its virtues as a balsamic and vulnerary. Its leaves, being bruised and applied to a fresh wound, cure it. They have also another use for it, twisting the dried leaves into a sort of match for their muskets. Phil. Trans. N° 232.

METACONDYLI is used by some authors for the outmost bones, or joints of the fingers, next the nails.

METADELO, plur. *Metadeli*, in *Commerce*, a corn and liquid measure at Florence. For corn, the moggio contains 24 stoja; and the stoja 16 metadeli; and the moggio contains about 16 English bushels. Oil is sold by the barile of 32 boccali or metadeli, the whole weighing 88lbs. of Florence, or about 66lbs. avoirdupois.

METAGITNION, μεταγειτνιων, in *Chronology*, the second month of the Athenian year. It contained twenty-nine days, and answered to the latter part of our July and beginning of August. The Bœotians called it *Panemus*, and the people of Syracuse, *Carnius*.

It is so called from *Metagitnia*, one of Apollo's festivals kept in it.

METAGONITÆ, in *Ancient Geography*, a people of Africa, who inhabited the environs of the promontory of Metagonium, on the west of Mauritania Tingitana.

METAKOONA, in *Geography*, a town of Hindoostan, in the province of Cattack; 60 miles S. of Cattack.

METALS, in *Chemistry*, a class of simple bodies possessing peculiar properties. The ancients, who valued these bodies

bodies most for their physical properties, did not bestow the exclusive name of metal on any body which was not malleable. Other bodies, which possessed similar characters, without being malleable, were called semi-metals. The peculiar brilliancy belonging to the metals is perhaps their most generally distinguishing character. The lustre exhibited by mica has some resemblance to the lustre of metals, but it is very inferior in degree, and is merely confined to the surface. The great specific gravity of most metals has been thought a sufficiently distinguishing character. This property, to a certain extent, was very striking. Till the late discoveries of Mr. (sir H.) Davy, the lightest of the known metals was of greater specific gravity than the densest body which was not a metal. The bases of potash and soda, however, have all the characters of metals, with the exception of being defective in the property just alluded to, since potassium and sodium are of less specific gravity than water. From these facts, therefore, we are no longer allowed to say that all metals are of greater specific gravity than other bodies.

In the present state of our knowledge there appear to be two classes of elementary matter, namely, oxygen, which constitutes one class, and oxydable bodies, or such bodies as combine with oxygen. Of the latter class, out of 45 varieties, there appear to be only five which are not metallic. The metals, therefore, comprise by far the greatest part of the elementary bodies.

Dr. Thomson has divided the metals into four classes: 1. Malleable. 2. Brittle and easily fused. 3. Brittle, and difficultly fused. 4. Refractory.

I. Malleable.

1. Gold.	8. Mercury.
2. Platinum.	9. Copper.
3. Silver.	10. Iron.
4. Palladium	11. Lead.
5. Rhodium.	12. Tin.
6. Iridium.	13. Nickel.
7. Osmium.	14. Zinc.

II. Brittle, and easily fusible.

1. Bismuth.	3. Tellurium.
2. Antimony.	4. Arsenic.

III. Brittle, and difficultly fusible.

1. Cobalt.	4. Molybdenum.
2. Manganese.	5. Uranium.
3. Chronium.	6. Tungsten.

IV. Refractory.

1. Titanium.	3. Cerium.
2. Columbium.	

Besides the metals arranged in this table, there are a number of others lately discovered by Mr. Davy, which are the bases of some of the earths, and the two fixed alkalies. If the whole of the earths, as well as the two fixed alkalies, have metallic bases, the number of metals to be added to the above will be 13. Those from potash, soda, barytes, strontian, zinc, and magnesia, have already been obtained, and have been named by Mr. Davy, potassium, sodium, barium, strontium, calcium, and magnesium. The four first of these appear to be malleable metals; the others are not sufficiently known.

Those metals which are not liable to be oxydated by exposure to the air, such as gold, platina, silver, &c. have been called noble; while those which become tarnished and corroded, were termed base metals. These distinctions have now become obsolete.

The metals have always, and must continue to be of the utmost importance in chemistry, in the arts and manufactures, and in domestic economy. Their malleability and hardness render them highly fitted for making various vessels and utensils, and their lustre and colour are agreeable to the eye. The properties of hardness and tenacity united, such as belong to iron and steel, are of great utility in various kinds of edge-tools, and the elasticity which is constituted by certain degrees of these two properties, could scarcely be furnished by any other substance than steel; hence its great usefulness for making springs.

The ductility of some metals is so great, as to admit of its being drawn into wires much finer than a hair. Gold, although the most laminable of all the metals, or which may be made into the thinnest leaves, does not admit of being drawn into the smallest wire, owing to its want of hardness. Iron, in consequence of possessing greater hardness, with a considerable portion of that property by which the particles of bodies attract each other in all situations equally, is capable of being drawn into finer wire than gold. Indeed pure gold is less ductile than when it contains a certain portion of copper. In treating of some of the physical properties of metals, such as malleability, ductility, hardness, and tenacity, much uncertainty has prevailed, from the want of some of these terms having definite meanings.

That property of a metallic bar or wire, by which it resists the action of a weight in the direction of its length, has been called tenacity, and this is always the measure of its strength. This power in metals, however, is evidently dependent upon two properties, one of which is its hardness, and the other a property for which philosophers have no precise word; perhaps the word flexibility may come the nearest. We mean, however, that property by which its particles can be changed into any situation, without separation. In the drawing of a piece of wire, some of those particles which constitute its thickness, before it passes through the hole of the wire-plate, are, by the process of drawing, brought into the direction of its length. This property in the greatest degree enables a piece of wire, or a thin slip of metal, to be bent backwards and forwards without breaking. A single experiment will satisfy any one of the propriety of these remarks. Take a piece of copper or iron wire, previously well annealed, and it will be found exceedingly flexible, and may be twisted or bent considerably, without breaking. If a weight be hung to it, with a view to break it, it will stretch considerably before it breaks. If a piece of the same wire be drawn through one or two holes, it will be found much stiffer and harder, and of course smaller: it will also be less capable of being bent or twisted without breaking. If, however, a trial be made of its strength, it will require a much greater weight to break it than in the annealed state; although its diameter is diminished. If the hardness be still increased by these means, a maximum of strength would be found under some joint proportion of the hardness, and the property of bending or twisting, which we may for the present call flexibility. It is on this latter property, with a certain degree of hardness, that the malleability and ductility of metals depend. It requires rather less hardness to make a metal to the best advantage into sheets, than to draw it into wire. This evil, however, of the wire breaking from being soft, may be remedied by making less difference in the size of the holes in the wire-plate. By this means the greatest ductility and malleability may exist under the same degrees of hardness and flexibility.

Metals, with regard to their hardneſs and flexibility, are very different under different circumſtances. Some metals, however, are more ſuſceptible of this change than others. Steel may be ſo ſoft and flexible as to bear much twiſting, and be eaſily penetrable by the file, which happens when it is newly annealed; while, if it is heated red-hot, and cooled rapidly, it becomes extremely brittle, and is ſufficiently hard to cut glaſs. Lead, on the contrary, under all circumſtances, has the ſame degree of ſtiffneſs and hardneſs. The ſame is pretty nearly the caſe with tin.

Some hints were given under the article LIQUIDITY, which may throw ſome light on this myſterious property of metals. It is there conjectured, that the particles of bodies may be capable of aſſuming two ſtates, one in which the particles attract each other equally in all directions. Hence whatever motion may take place among them, the ſame attraction ſtill exiſts. It is in this ſtate that bodies can be changed in their figure, without deſtroying their aggregation.

On the other hand, it is ſuppoſed that the particles of bodies, under certain circumſtances, may poſſeſs polarity; and that the ſtrongeſt attraction, and, conſequently, their greateſt hardneſs, may exiſt, when the particles are ſo arranged that oppoſite poles are preſented to each other. Any thing, therefore, which facilitates this change to polarity, will increaſe the hardneſs of a body. The cryſtalline form, which is common to ſome metals, ſtrongly favours this idea; ſince metals are always harder in this ſtate, than when their *fibrous form*, as it is called, is brought about. Metals ſeem to acquire the greateſt hardneſs by cooling rapidly, through a great range of temperature. It is in this change, therefore, that the particles acquire the greateſt polarity, and by which the body becomes the moſt brittle and elaſtic. Indeed it is on the principle of polarity only, that we are enabled to explain the elaſticity of bodies. Heat appears to be the moſt efficacious in deſtroying the polar property. The body would, however, regain it by rapid cooling; but by ſlow cooling, it is rendered ſoft to the greateſt degree of which it is capable, and in the ſame proportion malleable and inelaſtic.

The hardneſs of metals, when they have been annealed, may be conſiderably increaſed by hammering, rolling, or wire-drawing. This change appears to be brought about merely by condenſation. The ſmall degree of polarity left in the particles will exhibit itſelf in the elaſticity, when the particles are brought nearer together. It will be equally evident that the particles will be attracted with more force, and that the hardneſs will be increaſed. The hammering does not appear to increaſe the hardneſs of a body which has aſſumed the cryſtalline form, under which the greateſt polar power is ſuppoſed to exiſt, but rather to diminiſh it. If a piece of ſteel plate, which has been hardened and tempered, be hammered carefully, the elaſticity and hardneſs become leſs. Upon heating it, however, till it becomes blue, the elaſticity returns. The hammering, in this inſtance, deranges the poles of the particles, which the ſlight heat reſtores to their proper poſitions.

From what has been obſerved it will be eaſy to infer, that no metal can be malleable under its cryſtalline or polar form. Several of the metals are ſcarcely ſuſceptible of this form: among theſe we may enumerate gold, ſilver, and lead, and, in all probability, mercury. Others are deprived of it, and become malleable by hammering or rolling at a certain temperature. Of theſe are copper, braſs, iron, ſteel, tin, and zinc. There are other metals, indeed the greateſt part of them, which are not capable of any other than the cryſtalline form, and hence are not malleable. Of theſe we may mention antimony, biſmuth, arſenic, cobalt, and manganeſe. What ſtrengthens the idea that the cryſtalline form is the cauſe of the want of ſoftneſs and malleability, is the circumſtance of copper and tin being ſeparately very ſoft and malleable; though an alloy of theſe two metals is as hard as ſteel, and does not poſſeſs the leaſt malleability. Caſt ſteel and bliſtered ſteel are in the cryſtalline form, till they have been hammered at a certain temperature. In the firſt ſtate they are hard and brittle; in the latter, they are flexible, and are increaſed in tenacity.

Braſs wire appears to undergo ſome change in its arrangement, by hanging up in a damp room, or in ſituations where the fumes of acids prevail. It becomes ſo brittle as not to admit of bending to a right angle. This appears to ariſe from an increaſe in its polar form, for heating it red-hot partly reſtores its malleability.

The fuſibility of metals is a very valuable property, ſince it not only admits of their being caſt into almoſt any form, but the refuſe can be made into its original form, which allows of great economy.

Some metals are better fitted for caſting than others. It is obſerved, that all thoſe metals of which we have ſpoken as being ſuſceptible of the cryſtalline form, are the beſt calculated to take fine impreſſions. At that point in which the metal paſſes from the liquid to the ſolid form, a ſudden expanſion takes place, by which the volume is increaſed, and, in conſequence, preſſes more ſtrongly againſt the ſides of the mould. This is particularly the caſe with braſs, caſt iron, and copper with tin. In forming alloys the moſt fitted for caſting, a ſimple method offers itſelf. Let the ſpecific gravity of the ſolid be as much as poſſible leſs than the liquid. In ſuch bodies it will be found that the ſolid metals will float upon the liquid.

The property which metals poſſeſs of reflecting light, is highly important in the arts, ſciences, and in common life. The ſurfaces of many of the metals, when they are ſmooth and poliſhed, reflect almoſt all the light which falls upon them. White metals reflect more light than thoſe which are coloured. The hardeſt metals are beſt fitted for reflectors, becauſe they aſſume the fineſt poliſh. It has been thought that this property depended upon the denſity of theſe ſubſtances. This idea, however, ſeems incorrect, ſince ſodium and potaſſium, which are leſs denſe than water, appear to poſſeſs the power of reflecting light equal to many other metals. It is the great quantity of light which they reflect to which they owe their luſtre. The great facility with which metallic bodies conduct heat is of incalculable utility in the arts, and in the economy of human life. The boiling of moſt fluids would be almoſt impracticable in any other veſſels than thoſe of metal.

This property has been applied to great advantage in the proceſs of drying various articles. Large tubes of metal, being filled with ſteam, are kept conſtantly at nearly 212°. The goods to be dried are wrapped round the outſide of the tube.

The metal gives its heat with ſuch facility, as to dry the ſubſtances upon it in a very little time.

Metals are the beſt conductors of electricity, and hence are highly uſeful in electrical ſcience, as well as in preſerving the leſſer conducting ſubſtances from the effects of lightning.

The greater number of the metals are acted upon by the air, eſpecially when aided by heat. Metals were thought by the ancients to be compounds of an earth combined with phlogiſton. When theſe bodies were acted upon by the air, they ſuppoſed that the phlogiſton was ſeparated, leaving behind a calx, or earth. The ancients did not weigh their products, or elſe they would have found, that although this imaginary ſubſtance phlogiſton had eſcaped, yet the reſiduum was heavier than the original metal. By the greater accuracy

racy

Strahan and Preſton,
New-Street Square, London.

racy of modern experimenters, it has been found that the metal is the ſimple body, and that, by combining with the oxygen of the atmoſphere, the metal is converted into a ſubſtance of an earthy appearance, which, in modern chemiſtry, is called an oxyd of the metal.

The bodies formed by the combination of metals with oxygen, exhibit, as well as the metal, an ample field of utility to man. Theſe bodies, in various forms, are valuable auxiliaries in the healing art. Some of them conſtitute rich pigments of the utmoſt importance to the arts. Others are not leſs valuable to the dyer and the bleacher. Several metallic oxyds are uſed to great advantage for poliſhing marble, glaſs, and metals.

Metals *for Specula*. See Speculum.

Metals, *Colours from*. As metals have a ſtrong texture in their metalline form, ſo they preſerve their natural colours durable, unleſs corroded or diſſolved by particular menſtruums, after which their ſolutions ſtrike particular durable colours, or afford the ſtrongeſt ſtains.

Iron diſſolved in ſtale ſmall beer gives the beautiful yellow and different ſhades of buff colour, uſed in printing linens and cottons, &c. When ſublimed with ſal ammoniac it alſo affords a yellow; and the common iron-moulds made by ink are owing to the iron diſſolved in the copperas of which ink is made.

Copper melted with zinc appears of a gold colour; diſſolved in aquafortis, it affords a beautiful green; and in any alkali a beautiful blue. And theſe ſolutions may be reduced to dry colours by cryſtallization or evaporation; and the ſame metal, precipitated out of aquafortis with common ſalts, gives the turquoiſe colour to white glaſs. Tin, a white or colourleſs metal, affords a light blue colour, when fluxed with antimony and nitre. The ſame metal is neceſſary in ſtriking the ſcarlet dye with aquafortis and cochineal; and its calx, by ſtrong infuſion, turns to a glaſs of an opal colour.

Lead, corroded by the fumes of vinegar, gives the fine white ceruſs; burnt in a ſtrong naked fire, it becomes the ſtrong red-lead, or minium; and melted into a glaſs with ſand, is of the hyacinth colour. Shaw's Lectures, p. 171.

Silver being diſſolved in aquafortis, if chalk be put to the ſolution, turns of a beautiful purple or amethyſt colour; and its own ſolution, though pale as water, durably ſtains the nails, ſkin, or hair, brown or black.

Quickſilver, mixed with brimſtone, makes a black maſs, and this, by ſublimation, affords the beautiful red pigment called cinnabar, or vermilion; and the ſolution of quickſilver being precipitated with common ſalt, yields a ſnow-white powder, which alſo turns black by being mixed with ſulphur.

Gold, diſſolved in aqua regia, affords a fine yellow liquor, which ſtains animal ſubſtances beautifully purple; and if the ſolution be ſufficiently weakened with water, and mixed with a ſolution of tin, a fine red or purple powder may be procured, very uſeful for ſtaining of glaſs and paſtes to a beautiful red.

It appears, from the experiments of ſir Iſaac Newton, relating to the changes of colour that take place in pellucid colourleſs ſubſtances, that the leſs refrangible colours are exhibited by the greater thickneſs of air, water, and glaſs; and that as the thickneſs of thoſe ſubſtances is diminiſhed, they reflect the more refrangible colours. Hence he infers, that nothing more is requiſite for producing all the colours of natural bodies, than the ſeveral ſizes and denſities of their particles. Accordingly he attributes the colours of permanently coloured bodies to the ſame cauſe by which they were produced in colourleſs ſubſtances, *viz.* to the various thickneſſes of their component particles. But no experiments were made on permanently coloured bodies, in order to eſtabliſh the truth of ſir Iſaac Newton's opinion, till the ingenious Mr. Delaval directed his attention to this ſubject. From obſerving the circumſtances above recited, and more largely illuſtrated under the article Colours, it appeared to him, that, if permanently coloured bodies are ſubject to the ſame laws as tranſparent colourleſs ſubſtances are, all ſuch permanently coloured bodies, whenever the ſize of their particles is diminiſhed, ſhould undergo a change of colour, by aſcending from the leſs refrangible to the more refrangible colours; and that ſuch bodies, when the ſize of their particles is augmented, ſhould undergo a contrary change, their colour in this caſe deſcending from the more refrangible to the leſs refrangible colours. In order to confirm this concluſion, he made a great variety of experiments with vegetable, animal, and mineral ſubjects, whereby the ſize of their particles, upon which their colours depend, might be diminiſhed or increaſed. The methods which he uſed, in order to diminiſh the ſize of the particles of thoſe bodies which were the ſubject of inquiry, were by diſſolving, attenuating, &c. by means of chemical ſolvents, heat, putrefaction, dilution, &c. The contrary effects were brought about by ſuch means as are known to condenſe, incraſſate, or unite the particles of bodies into larger maſſes, as by coagulation, precipitation, evaporation, by diminiſhing the force of the ſolvents, &c. The metals afforded him numerous inſtances in confirmation of the doctrine above explained; for almoſt every operation, to which they are ſubject, exhibits a change of colour correſponding to this doctrine. This is particularly the caſe with regard to the imperfect metals; for every change of their texture is accompanied by a correſpondent change of colour. We can only enumerate ſome of the principal reſults which Mr. Delaval obtained from a great number of well-conducted experiments. Thus, the green vitriol of iron is changed, in proportion as it is deprived of its ſolvent part, by expoſing it to a ſtrong heat, &c. to yellow, orange, red, and purple; and by a contrary proceſs, *viz.* by a farther attenuation, by means of the phlogiſticated lixivium, in the proceſs of Pruſſian blue, &c. the colour of the iron aſcends from green to blue; ſo that all the primary colours are produced from the ſame metal, in proportion as its particles are attenuated or incraſſated. It appears, likewiſe, that when iron is divided into very ſmall parts by means of a large quantity of glaſs, and by a violent heat, its colour is blue; but in proportion as it is leſs divided, by the mixture of a ſmaller quantity of glaſs, or the application of leſs heat, its colours are green, yellow, and red. From iron diſſolved in its ſeveral menſtrua, colours are produced in proportion as the ſolvent power of thoſe menſtrua is greater or leſs. Thus, iron diſſolved in its ſtrongeſt acid ſolvent, the vitriolic acid, gives green; in its weaker acid ſolvents, the marine and nitrous acids, yellow and orange; and in its weakeſt acid ſolvents, the vegetable acids, red. The colours of the calces of iron precipitated from its ſolution in the vitriolic and nitrous acid, deſcend from green to yellow, and from yellow to red; whereas the changes of colour ariſing from the ſolution of theſe calces, proceed in a contrary order, and aſcend. Mineral ſubſtances are alſo frequently impregnated with iron, and their colours correſpond with the ſtate of the iron contained in them.

In the ſame manner the colours of the ſolution of mercury in the nitrous acid vary, in proportion as the ſolvent is extricated from it, from yellow to orange, and then to red. Thus alſo, thoſe ſubſtances which have the greateſt affinity with the acid of the corroſive ſublimate produced by

Strahan and Preſton,

by the solution of mercury in the marine acid, disengage from its solution a red precipitate; and those, whose affinity with it is less, produce a yellow one. But these colours are liable to some variation, according to the greater or less quantity of acid in the solution. Mercury dissolved in the vitriolic and in the vegetable acids, exhibits, in proportion as its solvent is taken from it, the same colours which, under similar circumstances, are afforded by that metal dissolved in the other acids. All these mercurial preparations become red, when they are deprived of the principal part of their menstruum; and mercury calcined by heat, without the addition of any acid, acquires the same colour. Its colour, however, is subject to variation, from the action of its solvents; and thus the phosphoric acid changes the red to yellow and white. The same law obtains in the changes of colour to which the mineral manganese is subject; for Mr. Delaval found, that by means of the different degrees of power in the several solvents, these colours were produced in their regular prismatic order, *viz.* yellow, green, blue, purple, and red. The various phenomena of the sympathetic ink of M. Hellot conform to the same law, and are urged by Mr. Delaval as arguments to establish it. Heat and cold, he observes, are not necessary agents in the production or suppression of the colour. But it appears, that the alterations are effected by the moisture of the air, attracted by the saline matter when cold, and expelled from it when heated. When this ink is exposed to a moderate heat, in a white China cup, and when the greater part of the water is evaporated, the saline matter becomes green. This colour arises from a superfluous quantity of the marine acid, which soon flies off, and leaves the remaining part blue, slightly inclining to green. It also forms a hard dry mass, which, in a few minutes after its removal from the fire, grows moist, and assumes a light red colour. These alterations may be often renewed, by alternately heating and cooling the coloured matter; which does not again become green, after the superfluous marine acid is once evaporated. But a drop of spirit of salt, added to the red or blue mass, immediately renders it green. When preparations of cobalt are acted upon merely by heat, the order of the changes of colour effected in them, is such as, in other instances, constantly arises from that means of attenuation. Thus, when the yellow solution of this mineral, in the marine acid, is heated, it assumes a green colour, passing from a less to a more refrangible colour. When this solution is cooled, the yellow is restored.

Mr. Delaval observes, that as the inflammable matter, in the entire metals, acts strongly on the rays of light, it is necessary to calcine or to divide them into extremely minute particles, in order to examine separately the action of the calx, or fixed matter, on the rays of light. In order, therefore, to examine all the metals in the like circumstances, by reducing them into the smallest particles, and depriving them of their phlogiston as much as possible, he exposed each of them, united with a proper quantity of the purest glass, without any additional ingredient, to the greatest degree of fire which they are capable of bearing, without having all colour whatever destroyed. In this state it appears, from a variety of experiments and facts, that they actually do, without any exception, exhibit colour in the order of their densities as follow: gold, red; lead, orange; silver, yellow; copper, green; and iron, blue. He has also shewn that the other preparations of the metals, *viz.* their solutions, precipitates, crystals, &c. do for the most part exhibit the same colour, in the order of their densities, though not so invariably as their glasses; some small variation of colour happening in the more imperfect metals, probably from a change of density in their different preparations. Thus, gold acquires a red colour, by a minute division of its particles, without any addition. In the process of calcining lead in the furnace, the first of the primary colours which it acquires is yellow; the calx passing from that colour through orange into red. This variety of colours proceeds from the imperfection of the metal; which, probably, during its calcination (as our author supposed), receives a small portion of phlogiston, as well as air; for the effect of such an union must probably be a change of colour from orange to red: as sir Isaac Newton has shewn, that bodies reflect more strongly in proportion as they possess more phlogiston; and that the less refrangible colours require a greater power to reflect them. The preparations of silver are yellow; the two most imperfect metals, copper and iron, being very easily acted upon by almost all menstrua, the colours of their solutions, &c. *viz.* green and blue, are apt to change into each other's order; the copper in some solvents becoming blue, and the iron green, and in other solvents *vice versâ*; which probably depends on the increase or diminution of their densities. The preparations, &c. of mercury have been already examined. The specific gravity of platina being nearly equal to that of gold, it is found, agreeably to the Newtonian doctrine, confirmed by Mr. Delaval, that the precipitates and crystals obtained from solutions of this metal are red; and that a solution of it in aqua regia to perfect saturation is of a dark red, though, when diluted, yellow. Delaval's Experimental Inquiry into the Cause of the Changes of Colours in opaque and coloured Bodies, &c. 1777, passim. Phil. Trans. vol. lv. art. 3, p. 10, &c.

METALS, *Fluxes of.* See FLUX.

METALS, *Granulation of.* See GRANULATION.

METALS in the *Materia Medica*, furnish medicines of considerable importance and utility. Although the operation of the pure metals on the animal system is merely mechanical, yet when they undergo oxydation, or are changed by acids into the state of salts, they acquire a high degree of activity, and become effectual remedies in many disorders, when they are judiciously administered. Mercury and tin have, indeed, been employed in their metallic state. For what purposes and with what effect they have been so used, we state under the articles MERCURY and TIN. But metals are more generally and with greater efficacy previously combined with oxygen, acids, sulphur, &c. This is the case with respect to antimony, arsenic, bismuth, copper, iron, lead, mercury, silver, and zinc. This combination, for medicinal purposes, is effected either by the action of atmospheric air, with an increased degree of temperature; or by deflagration with nitrate of potash; or by the action of water; or by solution in an acid, the acid being subsequently abstracted by an alkali, or by some substance for which it has a greater affinity than it has for the oxyd of the metal. When oxygen is united with a metallic base, or the combination denominated oxydation takes place, in whatever mode it is effected, and oxyds of metals are thus obtained, they are found to lose their lustre, tenacity, inflammability, and other metallic properties, and they are changed into earth-like substances, the weight of which is greater than that of the portion of metal that has been employed. The activity of the oxyds of metals on the animal system depends, with a few exceptions, on the quantity of oxygen with which they are combined. Metals, in consequence of oxydation, become capable of uniting with acids, and forming soluble salts. The "metallic salts," therefore, are oxyds combined with acids, whether the oxyd, previously prepared, be dissolved in an acid, or the salt be the product of the direct solution of a metal in an acid. In the latter case, the metal

metal first gains oxygen, either from a part of the acid itself, or from the water, or the air, which it decomposes; and the oxyd, thus formed, is then dissolved by the remainder of the acid. "The properties of the metallic salts are much varied by the previous degree of oxydizement of the metals; and this is a point, the fixing of which in pharmaceutical operations is of the first practical importance; for if in all the indefinite degrees of oxydizement the metallic oxyds combine with acids; the resulting salts must vary in as many shades as exist between the maximum and minimum of oxydizement. In the preparation of the metallic salts, therefore, the same strict attention is requisite in following one established and approved process."—"Many of the metallic salts are altered by exposure to the atmosphere; some effloresce and attract oxygen; some are altered in their properties by moisture; and others are reduced by the action of light; hence, all of them ought to be kept in well-stopped glass bottles; and perhaps these always should be either made of green glass, or otherwise rendered opaque. In compositions which require these salts to be dissolved in water, *distilled* or *filtered rain-water* should always be employed; and much attention is requisite to avoid combining them with incompatible substances, which may either chemically decompose them, or alter their medicinal properties." (Todd's London Dispensatory, 8vo. 1811.) For the principal metallic preparations used in medicine, see the several metals, *viz.* ANTIMONY, ARSENIC, &c. and also the names of these preparations as they occur in the order of the alphabet. But for a fuller account of them, with the instructions for combining them given in the London, Edinburgh, and Dublin dispensatories, we refer to the comprehensive and useful publication already cited. Part iii.

METAL, *Prince's*. See COPPER, GOLD-*coloured Metal*, and TOMBAC.

This metal derives its name from prince Rupert, whom some supposed to have been the inventor of it, in 1680. But the greatest perfection this metal was ever brought to, was by two Frenchmen, M. La Croix, and M. Le Blanc. Their methods of making the composition, though both beautiful, were very different. M. Le Blanc's was the brightest, and of the most elegant and lively colour; but M. La Croix's was greatly superior to that in ductility and softness, so that it was very easily malleable.

M. La Croix invented a sort of varnish or lacquer for his metal, which added a somewhat deeper tinge to it, as it was naturally rather too pale; and had this farther advantage, that while it remained on the metal, it preserved it from rust or decay. This is a very material point in regard to a metal of which copper is the basis, since that is, of all metals, most subject to be injured by the air, or by the contact of liquids of almost any kind. M. Le Blanc's metal is of a deeper, yet equally lively colour, and remarkably bright; and is of such a temper as to be admirably fitted for working. The whole history of these metals is, certainly, that they are composed of zinc and copper in different proportions the one to the other; but it is not easy, without the help of numerous experiments, to determine what is to be the true proportion for either.

The microscope, however, shews a manifest difference, which may lead somewhat towards it; for the metal of La Croix is seen to be composed merely of a number of irregular striæ, while the other is discovered to consist of always two regular beds of them, which meet in the centre of the piece; hence it is that this is always brittle, and will not well polish. The fabric of these metals was long kept a secret; but it was always to be discovered by melting it in a crucible in a strong fire, when it always sent up plain flowers of zinc, and the remaining metal appeared no other than copper altered by calamine; that is, common brass. Mem. Acad. Par. 1732.

METAL, *Bell*, is a composition of copper and tin melted together. See COPPER.

METALS, *Blueing of*. See BLUEING *of Iron*.

METALS, *Painting on*. See PAINTING.

METALS, *Rust of*. See RUST.

METALS, *Line of*. On Gunter's sector are sometimes two lines thus called, and noted with the characters of the seven metals, ☉, ☽, ☿, ♄, ♀, ♂, and ♃; their use is, to give the proportions between the several metals as to their magnitudes and weights. See SECTOR.

METALS, *Tincture of*. See TINCTURE.

METAL, *Over*, in *Gunnery*. When the mouth of a piece of ordnance, in disparting it, lies higher than the breech, it is then said to be "laid over metal."

METAL, *Under*, is when the mouth of a piece of ordnance lies lower than the breech.

METAL, *Right with*. When a piece of ordnance lies truly level, point-blank, or right with the breech, it is said to lie "right with its metal."

METALS, *Superficies of*, denotes the surface or outside of a gun.

METAL, in *Heraldry*. There are two metals used in heraldry, by way of colours, *viz.* gold and silver; in blazon called *or* and *argent*. See COLOUR.

In the common painting of arms, these metals are represented by white and yellow, which are the natural colours of those metals.

In engraving, gold is expressed by dotting the coat, &c. all over; and silver by leaving it quite blank.

It is a general rule in heraldry, never to place metal upon metal, nor colour on colour; so that if the field be of one of the metals, the bearing must be of some colour, and *vice versâ*; otherwise the arms are false: though this rule admits of some exceptions.

METALEPSIS, in *Rhetoric*, is a figure in which two or more tropes, and those of a different kind, are contained under one word; so that several gradations, or intervening senses, come between the word that is expressed, and the thing designed by it. Thus, when Sylla says of Julius Cæsar, *In one Cæsar there are many Mariuses*. Suet. in Vit. c. 1. This is a metalepsis. So when Virgil describing that part of the African coast, where Æneas arrived with his ships, says, *A dark wood hung over it*, Æn. lib. i. ver. 665; and in the words of Dido, Æn. lib. iv. ver. 664, the same figure is used. Thus, the Roman phrase of "Fuit," or "Vixit," expresses that a person was dead. "Fuit Ilium et ingens gloria Dardanidum" signifies, by metalepsis, that the glory of Troy is now no more.

METALLIC, or METALLINE, an adjective applied to any thing that bears a relation to metals.

METALLIC *Germination*, *Mines*, *Vegetation*, and *Vitriols*. See the respective substantives.

METALLIC *Solutions*, in *Agriculture*, such fluids as contain some sort of metal suspended in them in the state of solution or diffusion. These sorts of liquids were formerly supposed to have a highly noxious or poisonous effect when applied to plants as manures and taken up as food; but some late experiments made by Dr. George Pearson seem to lead to a different conclusion.

This is further confirmed by the remarks of professor Barton of America, who, in a letter to the doctor, states his having been several years engaged in an extensive series of experiments

riments relative to the effects of various stimulant substances, such as camphor, &c. upon vegetables, as well as on the absorption of certain powerful mineral substances into the organical system of vegetables. "In numerous instances, he has subjected the stems and leaves of plants, young and old, large and small, to the influence of the sulphats of iron and copper, and has found that both of these metallic salts are very greedily absorbed by vegetables, insomuch that he has detected the presence of iron in the vessels of a branch of a mulberry, at the height of five or six feet above the place of immersion in a solution of the sulphat of this metal."

He intends to communicate a full account of his experiments to the public in two memoirs. But suggests, in the mean while, that the sulphat of iron applied to vegetables in the manner he has mentioned, "is only a poison like almost every thing else, from the over dose," as mentioned by the doctor. "In several of his experiments, the branches of vegetables that were placed in vessels containing solutions of the sulphat of iron and copper, lived longer and exhibited more signs of vigour than similar branches that were placed in equal quantities of simple water. It is true, that in many other experiments these metallic salts proved fatal to his plants, but this was when he employed too large a dose. In like manner he has found several years ago that camphor, by greatly stimulating, often kills vegetables; and yet when properly dosed this is a very wholesome stimulant to plants; he had also found that large doses of nitre (which is unquestionably a powerful stimulant both with respect to animals and vegetables) produce an appearance like genuine gangrene in the leaves of vegetables; and yet it is certain that nitre, when it is judiciously dosed, may be made to greatly assist the healthy vegetation of plants.

METALLOID, in *Chemistry*, a name given to those metals which have been obtained from the fixed alkalies, and some of the earths. These bodies are so completely metallic, that they may, with the utmost propriety, be classed with the other metals, and such a distinction will therefore be unnecessary.

The metalloid said to be obtained from ammonia appears to have been given up by chemists. It was said to be produced by applying a globule of mercury at the negative end of a Galvanic battery, in contact with an ammoniacal salt. The mercury became of four or five times its original volume, and in the form of a soft solid. When this substance is exposed to the air, or thrown into water, the mercury assumes its original volume, and ammonia and hydrogen are exhaled. These appearances led Mr. (sir H.) Davy to conceive that the ammonia, like the other alkalies, contained a metallic base; and that during the Galvanic energy, this metallic base had been separated, and had alloyed itself with the mercury. From the great increase of volume, without a perceptible increase of weight, the specific gravity of this supposed base was deemed inconceivably small. Mr. Davy was more warranted in drawing this conclusion from some experiments, in which it appeared that ammonia contained oxygen. This fact, however, has been disproved by the experiments of Dr. Henry, and by those of Berthollet, jun. namely, that ammonia contains oxygen. The light amalgam produced in electrifying an ammoniacal salt with mercury, has been examined by Gay Lussac and Thenard, in their work entitled "Recherches Physico-Chimiques," tom. i. p. 52. The chemists consider the amalgam merely a compound of mercury, with hydrogen and ammonia. The phenomena which attend this process are in favour of such an opinion. Oxygen is given out in abundance at the positive wire, while a very little gas is observed at the negative wire, except when the mercury is removed. The writer of this article, seven years ago, discovered that when a wire coated with mercury is on the negative side in pure water, a much less quantity of hydrogen is evolved than what might be expected from the quantity of oxygen at the other wire; and if the battery be not of tolerable strength, no hydrogen at all appears.

In the decomposition of the amalgam, they found that the ammonia was to the hydrogen as 28 to 23.

On the ground that mercury has the property of combining with hydrogen, and from the great levity of the bases of potash and soda, Mr. Murray is of opinion that these substances are compounds of hydrogen with some metallic base, with which we are not as yet acquainted. In addition to this, he observes, that in the decomposition of potash and soda, no hydrogen is given out at the negative wire, although water is present; he therefore concludes that the hydrogen must combine with the metal. It must be remembered, however, that during the decomposition of any metallic oxyd by Galvanism, no hydrogen is given out, although water is present.

The metalloid obtained from barytes has not been noticed under that article, because these discoveries have all been made since that part of this work was published.

Soon after the discovery of potassium and sodium, Mr. Davy subjected barytes to the same decomposing power. He first exposed the moistened earth in contact with mercury to the Galvanic battery. He found that the mercury lost much of its fluidity by being alloyed with a metal. This amalgam, on being exposed to the air, became covered with a crust of barytes. When the same was thrown into water, hydrogen gas was evolved, and barytes formed. This proved the presence of a metallic substance, capable of decomposing water, which was the base of barytes. Mr. Davy next mixed the moistened earth with one-third its weight of red oxyd of mercury, and placed them upon a plate of platina in a small cavity, where was lodged a globule of mercury. These materials being covered with a thin film of naphtha, the plate was connected with the positive side of the battery, the mercury with the negative, the two metals being separated by the earth and the red oxyd of mercury. By the influence of a powerful battery an amalgam was soon formed. This amalgam was then introduced into a bent glass tube, and the mercury distilled off. Although the heat was raised to redness, it was still rather uncertain whether the base was perfectly pure.

Mr. Davy has given the name of barium to this metallic substance. It is a white metal of the colour of silver, different from potassium. It is solid at the common temperature, but becomes liquid at a heat a little short of redness. It is not volatile at a red heat. When exposed to the air it soon absorbs oxygen, becomes tarnished, and ultimately falls down in the state of white powder, having returned to its original state by the absorption of oxygen. When this metal is thrown into water, the latter is decomposed with great rapidity, hydrogen is evolved, and barytes formed. The specific gravity of this metal is greater than that of potassium or sodium, since it sinks in water, and even in sulphuric acid.

Mr. Davy thinks its specific gravity four or five times that of water. Barium appears to be a malleable metal, since it is capable of being flattened at the common temperature.

The proportion of oxygen with which it combines has not been ascertained. If barytes be the first oxyd of barium, and the weight of atom of barytes be 68, the proportion will be $\frac{68}{7} = \frac{100}{10.3}$, or 10 *per cent.* of oxygen, nearly.

For

For the rest of the metalloids, see the respective earths and alkalies.

METALLORUM *Crocus*, *Mater*, and *Sulphur*. See the respective articles.

METALLURGY, in a general sense, signifies the art of working metals under all circumstances. In its more limited meaning, it is confined to the art of separating metals from their ores. Since, however, these processes are given at full length under the heads of the metals respectively, it will be unnecessary to say more under this article. See ASSAYING and SMELTING.

METAMORPHISTS, in *Ecclesiastical History*, a sect of heretics in the sixteenth century, whose distinguishing tenet was, that the body of Jesus Christ was, upon his ascension into heaven, changed and metamorphosed into God.

METAMORPHOSIS, Μεταμορφωσις, formed of μετα, *change*, or removal from one place or state to another, and μορφη, *form*, or *figure*, *transformation*, the change of a person or thing into another form.

The ancients held two kinds of metamorphoses; the one real, the other apparent. The metamorphosis of Jupiter into a bull, and of Minerva into an old woman, were only apparent. That of Lycaon into a wolf, and of Arachne into a spider, and the like, they say, were of the real kind.

Most of the ancient metamorphoses include some allegorical meaning, relating either to physics or morality. Ovid's Metamorphoses is a collection of histories of such transformations, poetically related. Some authors are of opinion that a great part of the ancient philosophy is couched under them; and Dr. Hooke has made an attempt to unriddle and lay open the hidden meanings of several of them.

METAPARA, in *Geography*, a town of the island of Borneo; 70 miles S.E. of Nagara.

METAPEDIUM, in *Natural History*, a name given by some authors to a kind of stone, called by others *metatarsum*, and supposed to imitate a human foot. It is only a lusus naturæ in the formation of a common pebble.

METAPHOR, METAPHORA, μεταφορα, *translation*, or *displacing*, of μετα, *trans*, and φερω, *I bear*, or *carry*, in *Rhetoric*, a figure of speech, or a species of trope, whereby a word is transferred from its proper signification to another, different from it, by reason of some similitude between them; or whereby the proper denomination of one thing is applied to another: which other thing is more elegantly explained by this tralatitious or foreign name, than by that which naturally belongs to it. As, when we say, the light of the understanding; to burn with zeal; to float between hope and despair, &c.

The metaphor is the most common of all the figures of speech; and is that usually meant, when we say a thing is spoken figuratively.

The metaphor is a short simile; or, as Cicero calls it, a similitude reduced to a single word; an image being thereby called from its proper subject to give the resemblance of another. An allegory is no more than a continued metaphor.

Quintilian says, that a metaphor is a short similitude, and differs from it only in this, that the former is compared to the thing we design to express, and the latter is put for it. It is a similitude, when I say of a man, he has acted like a lion; and a metaphor, when I say, he is a lion. But though metaphors are usually taken from a similitude between two things; yet sometimes they are founded in the similitude which two things bear to each other, in some particular respect, by means of which what properly belongs to one of them is transferred to the other: the former of which are called *simple* metaphors, and the latter *analogous*. Hence the rudder of a ship may be called its reins; for what the reins are to a horse, that the rudder is to a ship, in guiding and directing it. Again, some metaphors are reciprocal in which the similitude holds either way. Thus to steer and govern are used reciprocally, both of a ship and a state; the proper expressions being to steer a ship, and govern a state, and the contrary metaphorical. From this account, therefore, of the nature of a metaphor, it may be defined, the application of a word, by way of similitude, to some other thing than what it properly signifies.

Quintilian distinguishes metaphors into four kinds: the first, when a word is transferred from one animal to another; as when Livy says, that Cato used to *bark* at Scipio; or when our Saviour calls Herod *fox*. To this class belong those forms of expression that occur in the sacred writings, by which the properties and affections of men are ascribed to the deity; as when God is said to hear, see, be angry, and repent, &c. The second, when the word is transferred from one inanimate to another; as *bridle* for *laws*; *floods* of fire, and *clouds* of smoke, denoting large quantities. The third, when inanimates are applied to animates; as the *flower* of youth. Thus, also, Homer calls Ajax the *bulwark* of the Greeks, and Cicero brands ill men with the character of being the *pest* of the state. And the last, when animates are applied to inanimates; as the river *disdained* its bounds. Thus Cicero speaking of Clodius says, the very altars, when they *saw* that monster fall, seemed to *move* themselves, and *assert* their right against him. Virgil, speaking of the impetuous force and rapidity of the river Araxes, says, it *disdained* a bridge. And it is a very usual epithet, which Homer gives to words, to call them πτεροεντα, or *winged*, to intimate the swiftness of speech. And metaphors of this kind, which give life and action to inanimate things, are esteemed the finest and strongest.

As the metaphor is intended to set things before the eyes, it becomes so much the more perfect, as it shews them the more vividly, by representing them in motion and action. Cicero, speaking of a metaphor, calls it the most florid manner of expression, and brightest ornament of language, that consists in single words. A metaphor should have nothing in it either coarse or shocking, or that may raise it above the simplicity of nature, so as to be forced and harsh; nor should it appear a metaphor to any, but those who view it very closely. A metaphor should never be carried too far; for, in that case, it degenerates into puerility. Metaphors should always be followed in the same kind; they become unnatural, when different images are introduced. In all metaphorical dictions, there should be a kind of suitableness to each other; different ideas are always absurd; as in this instance, the church was besieged with a deluge of troubles, where the two images, *siege* and *deluge*, have no relation.

The beauty of a metaphor is very strikingly exhibited in the following passages, extracted from lord Bolingbroke's Remarks on the History of England. Speaking of the behaviour of Charles I. to his last parliament, he says, "About a month after their meeting, he dissolved them; and as soon as he had dissolved them, he repented; but he repented too late of his rashness. Well might he repent; for the vessel was now full, and this last drop made the waters of bitterness flow."—"Here," he adds, "we draw the curtain, and put an end to our remarks." Nothing, as Dr. Blair observes, could be more happily thrown off. The metaphor, we see, is continued through several expressions. The *vessel* is put for the state or temper of the nation, already *full*, that is, provoked to the highest by former oppressions and wrongs; this

this *laſt drop* ſtands for the provocation recently received by the abrupt diſſolution of the parliament; and the *overflowing of the waters of bitterneſs*, beautifully expreſſes all the effects of reſentment let looſe by an exaſperated people.

There is nothing young writers are more faulty in, than the indiſcreet uſe of metaphors: thoſe who affect the marvellous, are eternally on the metaphorical ſtrain; nor know any bounds or reſtraint. They, who underſtand them beſt, uſe them with the greateſt reſerve. Mr. Addiſon propoſes it as a rule for writers, to imagine their metaphors actually painted before them, and to view and examine the juſtneſs of their application and aſſemblage under thoſe circumſtances; throwing every thing out of the writing, but what might be retained in the picture. Card. Perron preſcribes this general rule for metaphors, that they muſt always deſcend from the genus to the ſpecies; and never go backwards from the ſpecies to the genus: thus, we ſay figuratively, the *bonds of ſociety*, and not the *human cords*, which tie us together; *bond* being a genus, and *cord* a ſpecies.

We ſhall cloſe this article with a brief recital of the rules laid down by Dr. Blair as proper to be obſerved in the conduct of metaphors, which will alſo apply to tropes of every kind. Metaphors ſhould be ſuited to the nature of the ſubject of which we treat. They ſhould be neither too many, nor too gay, nor too elevated for it. The exceſſive or unſeaſonable employment of metaphors is mere foppery in writing; it gives a boyiſh air to compoſition, and, inſtead of raiſing a ſubject, in fact, diminiſhes its dignity, which ſhould ariſe from ſentiment and thought, not from ornament. This obſervation, as we have already ſuggeſted, demands the particular notice of young writers. A ſecond rule reſpects the choice of objects, from which metaphors, and alſo other figures, are to be drawn. Accordingly, we ſhould ſtudiouſly beware of even uſing ſuch alluſions as raiſe in the mind diſagreeable, mean, vulgar, or dirty ideas. Some approved authors have been incautiouſly betrayed into this error. Again, care ſhould be taken that the reſemblance, which is the foundation of the metaphor, be clear and perſpicuous, not far-fetched, nor difficult of diſcovery. The tranſgreſſion of this rule produces harſh or forced metaphors, which are always diſpleaſing, becauſe they puzzle the reader, and, inſtead of illuſtrating the thought, render it perplexed and intricate. Cowley is often chargeable with this fault. Farther, it muſt be carefully attended to, in the conduct of metaphors, never to jumble metaphorical and plain language together; never to conſtruct a period ſo that part of it muſt be underſtood metaphorically, part literally, which always produces a moſt diſagreeable confuſion. Moreover, two different metaphors ſhould never be made to meet on one object. This is what is called mixed metaphor, and is one of the groſſeſt abuſes of this figure; ſuch is Shakſpeare's expreſſion, "to take arms againſt a ſea of troubles." This makes a moſt unnatural medley, and confounds the imagination entirely. If we have occaſion to doubt whether metaphors be or be not of the mixed kind, we ſhould try to form a picture upon them, and conſider how the parts would agree, and what ſort of figure the whole would preſent, when delineated with a pencil. As metaphors ought never to be mixed, we ſhould alſo avoid crowding them together on the ſame object. Finally, metaphors ſhould not be too far purſued. This is called ſtraining a metaphor, and drawing it out into an allegory; by which we ſhall tire the reader, and render our own diſcourſe obſcure. Cowley, lord Shaftſbury, and Dr. Young, tranſgreſs in this way. Blair's Lectures, vol. i.

METAPHRAST, Metaphrastes, a tranſlator, or perſon who renders an author in another form, or another language, word for word.

A metaphraſe, μέταφρασις, uſually ſignifies ſomething more than either a paraphraſe, or a tranſlation: according to Baillet, a metaphraſt implies a tranſlator, gloſſator, and interpolator, all at once.

METAPHYSICS, Metaphysica, *Tranſnaturalis*, a branch of ſcience, about the nature and idea of which there is ſome difference among authors.

The word is formed from the prepoſition μετα, *trans*, *beyond* or *above*; and φυσις, *nature*, or φυσικη, *natural*.

Some define metaphyſics, that part of ſcience which conſiders ſpirits and immaterial beings; which others chooſe to diſtinguiſh by the name of *pneumatics*, or *pneumatology*.

Others, keeping cloſe to the etymology of the word, explain metaphyſics by *trans-natural*, or *præter-natural*, or even *poſt-natural philoſophy*: becauſe it is ſubſequent in contemplation to the phyſical, though prior to it in the real order of beings.

Others, with more propriety, conceive metaphyſics to be what ſome others call *ontology*, or *ontoſophy*, *i. e.* the doctrine *de ente*, or of being, *quatenus* being.

In the ſame view, ſome philoſophers call this ſcience by the name *philoſophia*, or *ſcientia generalis*, as being the foundation, or, as it were, the ſtamen or root from whence all the other parts of philoſophy ariſe, and wherein they all meet; its object being *being* in the abſtract, or general, not reſtrained to this or that ſpecies of beings; not to ſpirit any more than body; ſo that the doctrines of metaphyſics are applicable to all beings whatever.

Philoſophers, again, are divided as to the notion of a ſcience *de ente* in general. Some hold it real, preciſe, and ſolid enough to be demonſtrated; but others judge it too obſcure, faint, and confuſed, to be admitted into philoſophy.

Being, abſtracted from every ſort of ſpecies of being, is certainly a very vague term, and does not ſeem to give ſcope enough for a ſcience: we do not ſee how it can affect the mind as an object. Add, that the common metaphyſics cannot demonſtrate any part of its ſubject, but aſſume the whole: there are no principles or axioms, whereon to demonſtrate metaphyſics which contain the principles of all other ſciences.

The firſt who wrote profeſſedly on the ſubject of metaphyſics is Ariſtotle. Indeed, he is the firſt who uſes the word: Μεταφυσικα is the title of one of his books; but this ſome of his commentators will have to ſignify no more than *after the book of phyſics*. M. du Hamel, taking the prepoſition μετα in the ſenſe of *poſt*, is even of opinion, that the word was coined by Ariſtotle's followers: and that it was unknown to Ariſtotle himſelf.

Ariſtotle's metaphyſics ſeem to have been intended for a kind of natural theology. The metaphyſics of Ariſtotle have been lately illuſtrated by the ingenious Mr. Harris, in his treatiſe, intitled "Philoſophical Arrangements," 8vo. 1775.

Metaphyſics, ſays this ingenious author, are properly converſant about primary and internal cauſes; and the ſtudy of them is metaphyſical, becauſe, though prior in itſelf, it is ſubſequent in man's contemplation, whoſe road of ſcience is naturally upward, that is, from effect to cauſe, from ſenſible to intelligible.

Accordingly metaphyſics have been, not improperly, defined "the ſcience of the principles and cauſes of all things exiſting." Ariſtotle calls this ſcience "the firſt philoſophy," as it is not only ſuperior, but prior in the order of nature, to the whole circle of the other arts and ſciences. What is firſt in nature, however, is not firſt to man. Nature begins with cauſes which produce effects; whereas man aſcends from effects to causes. Hence, as "Physics" was the name given by Aristotle to the philosophy of body, some of his interpreters called that of mind "Metaphysics," thus intimating not only that its subject is more sublime and difficult, but that the study of it would be more properly and successfully undertaken "after that of physics." The followers of Aristotle were led to adopt this appellation by their master himself, who to the books in which he pretends to elevate the mind above things corporeal to the contemplation of God and things spiritual, prefixed the Greek words μετα τα φυσικα. However significant the name, in reference to the subjects which this science recommends, it has, from misapplication and abuse, as well as from the decline and extinction of the Peripatetic philosophy, sunk into disrepute: and although Malebranche and Mr. Locke have written much more clearly and consistently of metaphysics than any of the ancients; yet more modern writers have comprehended these subjects, which were formerly referred to metaphysics, under the appellation of PHILOSOPHY *of the Human Mind.* Under this article we propose to give a general account of it, and to mention the particular subjects which it includes.

METAPHYSICAL, something belonging to metaphysics.

The word is also used to denote something subtile, abstract, and refined. In which sense we say, such a reasoning, such a proof is too metaphysical, &c.

A metaphysical case is an imaginary or chimerical case, which can scarcely ever happen, or not without much difficulty; and which ought not to be laid down as a rule for common occasions.

METAPHYSICAL *Certitude, Distinction, Evidence, Form, Perfection, Universality.* See the respective substantives.

METAPHYSICAL *Sect*, in the *History of Learning*, is one of the two great sects into which the philosophical world was divided about the beginning of the 17th century. This sect followed the system of Des Cartes, and considered truth as attainable by abstract reasoning; and from a small number of abstract truths, deduced a long series of propositions, in order to arrive at a precise and accurate knowledge of God and nature, of body and spirit. The metaphysical philosophers, supposing that many things are known by man with the utmost certainty, discovered an undue propensity to form their opinions and doctrines into a regular system. The other sect was the *Mathematical.* (See CARTESIANS.) A branch of the Eleatic sect was denominated *Metaphysical*, by way of contradistinction to the *Physical.* See ELEATIC *Sect.*

METAPLASM, METAPLASMUS, compounded of μετα, and πλασσω, *fingo*, in *Grammar*, a transmutation, or change, made in the word, by adding, retrenching, or altering a letter or syllable of it.

METAPLEXIS, in *Botany*, so called by Mr. R. Brown, from μετα, *together*, or *between*, and πλεκω, *to plait*, or *connect*, alluding to the alternation of small leaves with the membranous-tipped anthers, composing a sort of wreath in the centre of the flower. Brown in Wern. Trans. v. 1. 48.—Class and order, *Pentandria Digynia.* Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juss. *Asclepiadeæ*, Brown.

Ess. Ch. Corolla somewhat wheel-shaped. Crown of the stamens of five dwarf-hooded leaves, alternate with the membranous-tipped anthers. Masses of pollen tumid, pendulous, attached laterally. Stigma with an elongated undivided beak. Follicles . . .

A twining smooth *shrub*, found by sir George Staunton, bart., in the province of Peckeley, in China. The *leaves* are heart-shaped. *Clusters* on stalks, inserted between the footstalks. *Limb* of the corolla bearded. No specific name is mentioned.

METAPTOSIS, a word used by many physical writers to express a change of one distemper into another, whether it be by *diadoche*, or *diadexis*, as it is called; when the change is for the better, and the morbid matter removes from a more noble to an ignoble part: or by *metastasis*, when the change is for the worse, and the morbid matter removes from an ignoble to a more noble part.

METASTASIO, L'ABATE PIETRO, in *Biography*, the best lyric poet and writer of operas, or dramas, for music in Italy, during the last century, or perhaps during any age, or in any country. This exquisite poet, second son of Felice Trapassi of Assisi, and Francesca Galasti of Bologna, was born at Rome, January 6th, 1698, in the parish of Santi Lorenzo and Damaso, where he was baptized the 19th of the same month, by cardinal Ottoboni. His father, though descended from a family in Assisi, which had long enjoyed the privileges of free citizens, but which, by a gradual decline, was reduced to poverty, not being able to subsist in the place of his birth, listed for a soldier in the regiment of Corsi, and soon after married Francesca Galasti, by whom he had many children besides the poet.

While he was in garrison, to the small pay of a soldier he added something towards the maintenance of his family, by becoming an amanuensis. And at length, having served the usual time, and by extreme industry and economy saved a little money, he entered into partnership with a shop-keeper at Rome, for the sale of goods which belong to what the Romans call *l'arte bianca*, consisting of oil, flour, pastry, and other culinary materials.

And having been somewhat prosperous in this kind of merchandise, he placed his two eldest sons, Leopoldo and Pietro, at a grammar-school. The latter discovered an extraordinary quickness and disposition for literature, and a violent passion for poetry, with a power of making verses, extempore, on any given subject, before he was ten years old.

This faculty he was habituated to exercise, after school hours, at his father's shop, where great crowds used to assemble in the street of an evening to hear the young Trapassi sing *all' improvista;* who, besides the harmony of his numbers, was gifted with the melody of a fine voice. During one of these tuneful fits, the learned civilian Gravina, having accidentally passed that way, was struck with the sweetness of the child's voice, and still more with his verses, which he soon found were extempore, and either upon persons who stood near him, or on playful subjects of their suggesting.

Gravina was so astonished and pleased at the precocity of the little bard's talents, that he stopt to caress and converse with him, offering him money for his performance, which, however, the child modestly declined to accept. This so much increased the civilian's admiration, that he instantly conceived a wish to adopt him, for the pleasure of cultivating a soil which nature had rendered so fertile, that even the spontaneous flowers and fruits it produced were of a superior kind. Without hesitation he therefore applied to his parents, soliciting them to transfer to him the care of their son's education, promising to become not only his preceptor, but father.

As the child was still to remain at Rome, and no cruel preliminary was mentioned, by which his natural parents were prohibited from seeing him, and cherishing reciprocal affection, Felix was too wise, and zealous for the welfare of his son, to refuse the proffered patronage; and the next morning, Pietro was conducted by his father and mother to the

the houſe of Gravina, and wholly conſigned to his care and protection.

Our young bard was now, from the legitimate child of a ſhop-keeper, become the adopted ſon of a man of letters. And as his learned patron was partial to Greek literature, and wiſhed to implant in the mind of the young Roman a reſpect and reverence for ancient lore, he tranſlated his name into Greek; calling him Metaſtaſio, inſtead of Trapaſſi; as Μεταςασις, Mutatio, ſeemed at once to expreſs his former name of Trapaſſi, and his new ſituation as an adopted child.

And having changed his name, he undertook the more difficult taſk of changing, or at leaſt enlarging, his mental faculties; and at the ſame time that he was ſtudying the learned languages, and imbuing his mind with the ſciences, he wiſhed to make him an orator rather than a poet, and determined that he ſhould ſtudy the law as a profeſſion; that and divinity being the only two roads by which a man of learning could arrive at honours and dignity in Rome. Poets, indeed, were rewarded with barren praiſe and acclamation, but wealth and affluence were ſtrangers to their doors.

Yet while he was obliged to read the dry books of the law, and was ſeemingly occupied by other ſtudies, he found time, by ſtealth, to read the great models of the art of poetry, for which his inſtinctive paſſion increaſed from the difficulty of gratifying it. At the name of Homer and Arioſto, his favourite poets, he was unable to contain himſelf; and Gravina diſcovering, in ſpite of his pupil's determination to conform implicitly to his will, that this excluſive paſſion for poetry was inſuperable, at length permitted him to read thoſe poets which he himſelf thought not only the beſt, but the only models of perfection. At the age of fourteen, during the early period of this indulgence, Metaſtaſio produced his tragedy of "Giuſtino," conformable to the rigour of all the rules of the ancient Greek dramatic writers, with which his learned preceptor had ſupplied him.

We have his own opinion of this production, in a letter written to ſignor Calſabigi, in which he ſays: "I ſhould have wiſhed that none of my early productions, which favour too much of adoleſcence, might have appeared in the Paris edition, particularly the tragedy of Giuſtino, written at fourteen years of age: when the authority of my illuſtrious maſter did not ſuffer me to move a ſtep from the moſt religious imitation of the Greeks; and when my inexperience and want of diſcernment were unable to diſtinguiſh gold from lead, even in thoſe mines themſelves, of which he then began to diſplay to me the treaſures."

After producing this tragedy on the favourite model of his patron and preceptor, the learned civilian ſeems not only to have tolerated, but encouraged his pupil's adoration of the muſes; and at eighteen carried him to Naples, expreſsly to afford him an opportunity of ſinging extempore with the moſt celebrated improviſatori of Italy at that time. Metaſtaſio, in a letter to Algarotti, written in 1757, gives the following account of this poetical contention: "It is your wiſh to have ſpecimens of the verſes which I made extempore, during my childhood; but how can I poſſibly gratify this wiſh? I do not deny but that a natural talent for harmony and the muſes was diſcovered in me, that was thought ſomewhat uncommon, and more early than uſual, that is, at ten or eleven years old; that this phenomenon ſo dazzled my great maſter Gravina, that he was partial to it, and cheriſhed me as a ſoil worthy of his cultivation: and that, ſo late as the year 1716, he exhibited me to ſpeak verſes, God knows how, for the benefit of Georgio Lorentino, upon all kinds of ſubjects; at which time I had for competitors the illuſtrious Rolli, Vagnini, and the cavalier Perfetti, men who were then arrived at full maturity, and veterans in Pindaric battles."

At twenty years of age he had the misfortune to loſe his learned preceptor and patron, Gravina, who died in 1718, aged fifty-four. It has been doubted whether this event, which his heart inclined him to regard as the greateſt calamity, was not a fortunate circumſtance for his fame. Metaſtaſio, whoſe writings evince him to have been all tenderneſs, gratitude, and diſintereſted ſenſibility, bewailed this misfortune with the deepeſt affliction; and in the elegy, called "La Strada della Gloria," written on this occaſion, and read at a full aſſembly of the members of the arcadian academy founded by Gravina, he gave a public teſtimony of his ſorrow and gratitude, expreſſive of thoſe noble ſentiments, which he cheriſhed and practiſed to the end of his life. Nor did the beneficent will of his maſter diminiſh his grief or dry his tears, though, when opened, it was found to have been made in 1717, and that he had appointed him his heir.

By this liberal act, he verified his promiſe to the parents of Metaſtaſio, of treating him as his own child. The advantage to his talents and to the lovers of poetry, which is ſuppoſed to have been derived from this early loſs of his learned tutor, was the opportunity it afforded his genius to free itſelf from the trammels of Grecian rules and ſervile imitation. But though in his dramas he has more pathos, poetry, nature, and facility, than we are now able to find in the ancient Greek tragedians, yet his early ſtudy of them certainly elevated his ideas and ſtyle, and taught him how to ſhun the vulgarity and abſurdities with which the early popular dramatiſts of moſt countries abound. He may be ſaid to write with claſſic elegance, though he had liberated himſelf from claſſic chains.

Gravina's bequeſt to Metaſtaſio conſiſted of 15,000 Roman crowns, between 3 and 4000 pounds ſterling in money, an excellent library, and a great quantity of rich furniture, with three ſmall places of which he had put him in poſſeſſion before his deceaſe, and a little eſtate in the kingdom of Naples.

But our young poet, now become a free agent, and a deſpotic prince over no contemptible fortune, among all his acquirements had not the leaſt idea of prudence and economy. His converſation and verſes had too much excellence to want admirers; and his table was too well ſerved to want gueſts. He now wholly quitted the dry ſtudy of the law, and entirely devoted himſelf and his fortune to the muſes and his friends. There was no poetical aſſembly in which he did not read ſome new production: as our Garrick, in the early part of his life, was found wherever lovers of theatrical amuſements were aſſembled. Stimulated by the applauſe which every piece univerſally received, Metaſtaſio thought of nothing but how to have it renewed by another compoſition. The love of praiſe is an infirmity to which the beſt minds are perhaps the moſt ſubject. During this intoxication, not a thought ſeems to have been beſtowed on his preſent finances or future fortune. If he reflected at all during theſe times of diſſipation, it was on the number of his friends and admirers, and the certainty of patronage whenever he ſhould want it. What his predeceſſor Petrarca has ſaid of the temple of love, was ſtill more applicable to that of fortune by Metaſtaſio.

"Errori, ſogni, ed immagini ſmorte
Eran d'intorno all' arco trionfale,

E falfe opinioni in fu le porte,
E lubrico fperar fu per le fcale."

" Errors and dreams and thoughts half form'd abound,
And crowd the bafelefs fabric all around;
While at the threfhold falfe opinions ftand,
And on the fteps, vain hope, with magic wand."

His patron's legacy was foon diffipated, not in the fupport of vice, but munificence and good cheer; fo that at the end of two years, finding himfelf wholly reduced to his two fmall Roman places, his Neapolitan poffeffions, and his library, he went to Naples with the firm refolution of ferioufly refuming the ftudy of the law. Being arrived in that city, 1720, he placed himfelf under the guidance of an advocate of the name of Paglietti, earneftly entreating his affiftance in the ftudy of jurifprudence, and promifing, on his own part, to fecond the inftructions which he fhould receive with all poffible diligence and docility. Paglietti was one of the moft eminent lawyers, at that time, in the city of Naples; but fo rigorous a difciplinarian, and fo totally devoted to his profeffion, that he not only defpifed but abfolutely hated every fpecies of ornamental knowledge or literature. Poetry was therefore ranked by him among the moft deadly fins of which an advocate could poffibly be guilty.

It is natural, therefore, to fuppofe that Paglietti, devoid of all tafte for the arts of elegance, which help to humanize and polifh our favage nature, was rough, four, and forbidding in his addrefs and manners: he was all law, and of that fevere and mercilefs fort, which knows not how to pardon the fmalleft imprudence or deviation from worldly wifdom.

Metaftafio was not ignorant of his feverity and invincible hatred for poetry; but inftead of looking upon it as an evil, he was the more eager to place himfelf under his moft rigid difcipline, in order to prevent a relapfe into poetry, which had hitherto been to him fo unprofitable a ftudy. The reception of Metaftafio by this Lycurgus, and his firft lecture, were perhaps rendered more auftere and acrid by the fame of his poetical talents, with which not only Naples but all Italy was already filled; but Metaftafio, hearing it with heroic patience, renewed his promife of unwearied application, and kept it fo well during his firft refidence under the advocate's roof, that he began to entertain great hopes of his becoming an excellent lawyer, and treated him with as much fweetnefs as his bitter nature would allow. He knew that the ftudies of his young difciple were frequently impeded by the vifits of perfons of learning and diftinction, to whom his poetical abilities were well known, and who remembered him when he was brought to Naples, as an *improvifatore*, by Gravina. But now their expectations were transferred to his legal abilities, upon which, from his learning and application, they had formed the higheft hopes. It is certain that Metaftafio, at this time, exercifing the greateft tyranny over his natural inclination, refrained entirely, not only from writing verfes, but from fpeaking them extempore, in fpite of all folicitation. The firft breach of contract with the rugged advocate, and firft feduction of the mufe during his refidence at Naples, was in the beginning of 1721, at the inftigation of the countefs of Althan, who prevailed on him to write an Epithalamium for the nuptials of her relation, the marquis Pignatelli, with a lady of the Pinelli family: it confifts of near one hundred octave ftanzas, is full of elegance, and in the higheft clafs of poetry. The drama of " Endymion," the firft that he produced exprefsly for mufic, is faid to have been written on the fame occafion.

Metaftafio's next infringement of the laws laid down by the advocate Paglietti againft the wicked practice of poetry, was occafioned by an application from the viceroy of Naples himfelf, that he would write a drama for mufic, to be performed on the birth-day of the emprefs Elizabeth, confort of the emperor Charles VI., who was then in poffeffion of that kingdom. It is faid that he was with difficulty prevailed upon to enter on this tafk, and only complied upon a promife that it fhould be kept a profound fecret. Our bard, in perpetual fear of the inexorable lawyer, was obliged to facrifice his hours of fleep to this contraband commerce with the mufes. The piece was entitled " The Gardens of the Hefperides," and is one of the moft beautiful of his early productions.

The next drama that was written at the expence of his legal ftudies, or his moments of reft and recreation, was " Angelica." This was printed at Naples in 1722, and fet to mufic by Porpora for the emprefs's birth-day. It has been faid in fome accounts of Metaftafio's early productions, that Farinelli's firft public performance was in this ferenata.

The poems which he produced at Naples were the admiration of all perfons poffeffed of a love and tafte for poetry, particularly " The Gardens of the Hefperides;" but none felt its beauties fo forcibly as the Bulgarella detta Romanina, the greateft female finger and actrefs of her time; who, having performed the part of Venus in that occafional drama, was fo enchanted with the uncommon beauty of the poetry, that fhe could not reft till fhe had been introduced to the acquaintance of the author. Indeed, tradition fays, that this drama had an effect upon the audience in general, which Naples had never before experienced. The recitative was hardly begun, when the fpectators formed a more curious fpectacle than the actors themfelves: fo great was the change in their behaviour and mode of liftening that was inftantly produced. Violent noife and unbridled clamour ufed to reign in every part of that theatre, and could never be fubdued but with great difficulty, even when fome capital finger had a favourite air to perform; and it was no fooner over than the din was renewed with fuch vehemence, that even the orcheftra could not be heard. But now, every one delighted by the new and decorous arrangement of the fcenes, original beauty and fweetnefs of the verfe, the force of the fentiments, the texture of the parts, and all the wonders of Metaftafio's dramatic poetry, was forced, almoft infenfibly, into profound filence and attention.

Univerfal curiofity was excited, and inquiries made, after the author, who, though a poet and fond of praife, is faid to have wifhed to lie concealed. But the Bulgarini, who was not only pleafed in common with the lovers of poetry, but impreffed with the moft lively gratitude to the author of the " Hefperides," for the flattering reception and unbounded applaufe which this piece had procured her, both as an actrefs and finger, was impatient to be perfonally acquainted with him. And having difcovered that fhe knew one of his intimate friends, fhe prevailed upon him to try to bring the poet to her houfe. He at firft refifted the folicitation; but at length, ceafing to be inexorable, he was induced to make her a vifit. The Romanina (as fhe was generally called from being a native of that city) had no fooner feen him, than fhe felt an uncommon regard for him. His poetical abilities, elegance of manners, and fine countenance, together with the circumftance of his being her countryman, or rather townfman, all joined to increafe her regard; while Metaftafio on his part felt equally unable, with all the ftoicifm he could mufter, to refift the defire of improving the acquaintance; and frequently returned to enjoy the pleafure of her converfation.

He had foon reafon to believe, from the countenance and

 behaviour

behaviour of Paglietti, that neither his theatrical production, nor the new ſtage acquaintance which he had made, was unknown to him. The praiſes he received from the Romanina, and all thoſe to whom the ſecret had been divulged, and their preſſing inſtances that he would continue to write, awakened his paſſion for poetry, which he had flattered himſelf was wholly ſubdued. He now began to feel, that by the narrow and contracted ſtudy of the law, his genius could never expand in his own original ideas, but would be conſtantly tied down to thoſe of others. His reflections upon the ſordidneſs of ſacrificing his whole life to a diſtaſteful buſineſs, for the mere hope of acquiring wealth, (as he afterwards confeſſed to his confidential friends,) joined to the harſh treatment of the old advocate, which became more intolerable in proportion as the aſſiduity of Metaſtaſio diminiſhed, entirely determined him to quit both him and his profeſſion.

His female friend perceived the conflict and internal war; and in order to ſtimulate his courage and reſolution, ſhe and her huſband invited him in the moſt preſſing manner to reſide under the ſame roof, and aſſured him that they would contribute every thing in their power to render his life as eaſy and comfortable as poſſible. He remained ſeveral months in a ſtate of uncertainty; but at length determined to accept their offer, to return to poetry, and to enjoy the pleaſures of ſociety in full liberty. Yet he did not ſeem inſenſible of the apparent indecorum and want of fortitude which he manifeſted in quitting, with ſuch ſeeming levity, the purſuit of ſtudies which had been recommended to him by his deceaſed patron. Nor was he quite at his eaſe on the ſide of delicacy, as to appearances; the obligations to the Bulgarini, under which he was loading himſelf, frequently oppreſſed his mind. And yet ſo limited is our power of penetrating into future events, that the meaſures which he now purſued, far from impeding either his fame or fortune, were the foundations of all his ſubſequent celebrity. An Italian poet has well deſcribed the ſhortneſs of mental viſion.

> " Sebben ſembra talor che torvo e iniquo
> Il volto verſo noi volga la ſorte;
> Ella ſeguendo ſuo coſtume antiquo
> A inaſpettata gioja apre le porte:
> E aſconde ſpeſſo ſotto calle obbliquo
> Della felicità le vie più corte:
> Onde non ſappia in mezzo ai torti, e ai guai
> L'uom che temer, nè che ſperar giammai."

> " Blind to the future, while he ſojourns here,
> Man knows not what to hope or what to fear;
> Amidſt misfortune, ſorrow, and diſmay,
> Fate oft, in frowns, points out the ſhorteſt way
> To fortune, fame, and unexpected joy,
> By means which prudence trembles to employ."

The Bulgarini was engaged to ſing in the theatre of Naples, during the carnival of 1724; and being very ambitious of appearing to as much advantage in the next opera as ſhe had done in that for the birth-day of the empreſs, ſhe preſſed the poet to write a drama, in which, as firſt woman, ſuch a character might fall to her ſhare, as would give her an opportunity of diſplaying all her powers, both as an actreſs and ſinger. It is eaſy to imagine with what zeal the Abate went to work, in order to gratify her wiſh. After many heroines had paſſed in review, Dido was at length choſen, and the drama, entitled " Didone Abbandonata," produced; in which he choſe the period of the hero, Æneas, quitting the Carthaginian queen: as it furniſhed ſcenes of the greateſt force and paſſion, as well as more expreſſion for his pen, and more abundant opportunities for the diſplay of the Romanina's abilities, than any other. This was the firſt perfect muſical drama, perhaps, that ever graced the Italian ſtage. The applauſe it obtained was equal to that of the " Orti Eſperidi;" and though the ſtory was ſo well known, that no effects could be produced by ſurpriſe, yet the pleaſure of the audience was exceſſive. It was ſet by Sarro, and the part of Æneas was performed by Nicolini.

From the great and ſudden celebrity of " Didone," which, immediately after its firſt appearance at Naples, was ſet by the beſt compoſers of the time for the other principal theatres of Italy; the Venetian miniſter at Rome, where it had been performed to Sarro's muſic, was inſtigated to apply to Metaſtaſio to write the opera of " Siroe," which he ſent to Venice, where it met with a ſucceſs equal to that of Dido, to the great emolument of the author, who was magnificently rewarded for the ſuperior excellence of his poetry. This drama was ſet by Vinci at Venice, and performed and printed in 1726.

It appears from the original *libretti*, or printed books of the words, that the Romanina not only performed the principal female part in Metaſtaſio's four firſt dramas at Naples, but in " Didone" and " Siroe," with Nicolini, at Venice, in which city they were firſt repreſented in 1725 and 1726; and, according to Quadrio, (Storia d'ogni Poeſia,) Metaſtaſio himſelf was at Venice during theſe performances. It was during this period that he altered the old opera of " Siface," for the ſame performers, at the requeſt of Porpora.

In the carnival of 1726, while the dramas of Metaſtaſio received ſuch unbounded applauſe at Venice, " Didone," as ſet by Vinci, was received at Rome with acclamation. The famous ex-jeſuit Cordara, who was there at that time, in his eloge of Metaſtaſio, recited at Alexandria in 1782, deſcribes its reception in the following manner:

" Every ſcene produced one continued applauſe. But who can deſcribe the rapture of the pit, when the queen of Carthage, diſdainfully riſing from the throne, repreſſes the inſolent pretenſions of the king of Mauritania, with the dignity of an independent princeſs, by the ſpirited air, " Son Regina," &c.? The noiſe ſeemed to ſhake the theatre to its foundation. I was not there myſelf, as my habit did not allow me to be preſent at ſuch ſpectacles; but I almoſt heard the rumour in my cell, ſo full was all Rome with the fame of this production."

In 1727, the Romanina having fulfilled all her theatrical engagements at Naples and elſewhere, prepared to return to Rome, yet declared at the ſame time, that ſhe would never ſee her native city again, unleſs in the company of her dear friend. He remained for a while irreſolute; but, at length, the warm affection he retained for the place of his nativity, in ſpite of the neglect and diſappointment which had driven him thence, heightened perhaps by his regard for the Bulgarini, and fortified by the deſire of ſeeing his father, and the reſt of his family, determined him to quit Naples, in company with his benefactreſs; but not before he had obtained a promiſe from her, that, in return for the hoſpitality which he had received under her roof at Naples, ſhe and her family ſhould become his gueſts at Rome. To this propoſition all parties having acceded, he wrote to his agents, to provide a houſe ſufficient for the two families of Trapaſſi and Bulgarini. And from the time of his arrival in that city, till his departure for Germany, they all lived under the ſame roof, and conſtituted one family. The Romanina, as more rich and accuſtomed to the management of a family, was inveſted with the ſuperintendance of all houſhold concerns: the reſt had nothing to do, but to attend their own purſuits; while

while Metastasio received visits, wrote verses, improved his circumstances, and increased his celebrity.

The first drama which he produced, expressly for Rome, was "Catone in Utica," which was set by Vinci, and performed in that city, 1728; and in 1729, at Venice, to the music of Leo. He chose the subject purposely to please the Romans, supposing that he should gain both applause and gratitude, by displaying the virtue of one of their own heroes. But as it seldom happens that a prophet or a poet (which in ancient times were united in the same person) receives due honour in his own country, particularly at Rome, which is proverbially called the residence of strangers; in spite of the excellence of this drama, which abounds with sublime, as well as tender sentiments and delineations, of the passions of glory, ambition, anger, and love; and in which the conduct was natural, and catastrophe historical; it was instantly attacked by the satirical genius of the Romans, and the performance suspended. The frivolous scenes, and feeble poetry to which they had been long accustomed, had corrupted the taste of the Roman public in general; and, except a few learned men, less invidious than the rest, who, if they knew of no modern Cato, had read, at least, something about the ancient, this piece was at first very coldly received; though afterwards, when their minds and tastes were enlightened and refined by other original and beautiful works of our author, this drama was treated with more justice.

The next opera which our author produced was "Ezio," set by Porpora, in 1728, and "Semiramide Riconosciuta," set by the same composer, 1729; but though both these dramas were received in the most favourable manner, and the praises bestowed upon the poet were unbounded, his fortune was not greatly improved by their success. Poetry has more frequently enriched the bookseller than the author, in every country; but at Rome, it is a drug of less value, even to the bookseller, than elsewhere; and Metastasio's muse, however chaste, was but little better treated for not being meretricious. If Metastasio had been a mere psalmodist, or hymnologist, his monkish rhymes might have obtained him some ecclesiastical preferment; but the poetry which he produced on pagan and secular subjects precluded him from every avenue to the church. He was, however, far from necessitous; and with the assistance of the Romanina, whose purse was always at his service, his fortune and situation were tolerably easy. But the being sometimes obliged to avail himself of the liberality of his generous friend, was a circumstance which humbled and mortified him beyond any other. He could not bear to reflect on being a burthen to her, for whom chiefly he wished to be rich, not only to exempt her from the expences which she incurred on his account, but to manifest his gratitude for the benefits she had already conferred on him.

His amiable friend tried every means in her power to set his mind at ease, concerning his obligations to her: assuring him that he had contributed much more to her professional fame than it had been in her power to do to his fortune; that she was in such circumstances as rendered the small friendly offices, which she had been able to perform, more a pleasure than an inconvenience; and pressed him, in the most urgent manner, to tranquillize his mind on that account, and to believe (which she assured him was the truth) that he was doing her the greatest favour, when he afforded her an opportunity of dividing with him her possessions.

The afflicted poet drew some comfort from these declarations, but it was of short duration. He was perpetually convinced of the ingratitude of his pretended Roman friends, and the duplicity of his protectors; and having nourished in his soul an ardent passion for general esteem, respect, and admiration, his narrow circumstances threw him into so profound a fit of melancholy, that he became incapable of receiving consolation.

Such was his state of despondency in 1729, when, to his great astonishment, he received a letter from prince Pio of Savoy, inspector of the imperial theatre at Vienna, inviting him to engage in the service of the emperor Charles VI., as the successor of Apostolo Zeno, who, from the year 1718, had filled the place of imperial laureate, whose chief employment had been to furnish dramas for music; and these had been justly thought the best which the Italian language could boast.

Metastasio was infinitely more surprised and flattered by this unsolicited and splendid offer, from finding that he had been recommended to the emperor's notice by the learned Zeno himself, who, growing in years, wished to retire to Venice, the place of his nativity, and had been applied to by his imperial majesty to recommend a successor.

And yet the offer of this employment to Metastasio, however dazzling, was not long productive of joy without deduction. The quitting Rome, for which he had always a filial fondness, as well as leaving his family, friends, and, perhaps more than all, the Romanina, impressed his mind with a sorrowful allay to his happiness.

Upon consulting with his family, they instantly conceived such magnificent hopes of his future aggrandizement, as contributed much to their consolation at losing him; and the Romanina was so generous and disinterested, in spite of secret affliction, as to use her utmost eloquence in removing his doubts, and diminishing the causes of his repugnance, at quitting Rome and his friends.

After many consultations and discussions of the several arguments for and against the acceptance of the proposition from Vienna, the answer which he sent, and which has been printed among his letters, contains so many characteristic traits of modesty, propriety, and delicacy, that it deserves to be preserved as a model of conduct under similar circumstances.

The result of meditation, and the advice of his family and friends, was to accept the appointment, and to throw himself at the feet of his imperial master as soon as he could arrange his affairs, and fulfil his engagements to furnish the Roman theatre with two new operas for the ensuing carnival.

His appointment at Vienna was settled at three thousand florins *per annum*, and fifty pounds sterling for the expences of his journey. After completing his two new dramas for Rome, which were "Artaserse" and "Alessandro nell' Indie," and which were both set by Leonardo Vinci, and performed before the poet's departure, he left his native city with a heavy heart, and a most sovereign contempt for the friendship and flattering promises of the great, by whose delusions he had so long entertained hopes of preferment in his native city; whence, at last, he was driven into a kind of splendid banishment, for the rest of his life. These early disappointments, from being extremely credulous, rendered him incurably sceptical, as to all future presages of good fortune; and the effects of hoping too much in early life, and too little after, produced, perhaps, the principal defects in his character.

Upon quitting Rome, Metastasio consigned into the hands of his zealous and affectionate friend, the Romanina, all his effects, interests, and concerns; together with the management of his family affairs: she most willingly submitting to

 these

these several tasks, as well as to the care of the produce of the little places, and sums of money, which he left behind him.

Of his reception at Vienna, where he arrived in July, 1730, by prince Pio and his imperial patron, there is among his letters an account written by himself to a friend at Rome, the day after he had been presented. It was to the highest degree flattering. And the emperor, who was of a grave, religious, and moral character, seems to have honoured him not only with his favour but affection, on finding in him principles congenial with his own.

In his correspondence with the Romanina, we have an account of his occupations at Vienna, during the first three years of his residence there; and the reception of his operas of "Adriano in Siria," "Demetrio," "Issipile," and his oratorio of "Sant' Elena al Calvario."

In 1734 he lost the friend of his head and heart, the Romanina, who died at Rome, and manifested the sincerity of her attachment to the poet, by bequeathing to him all her possessions, after the decease of her husband, to the amount of twenty-five thousand crowns. But Metastasio, always consistent with his usual rectitude and propriety, totally declined accepting of her intended kindness, and transferred the whole bequest to her husband, whose real property, according to our English ideas of jurisprudence, it seems legally to have been. The testamentary laws of Italy may be different from those of our country. Some Italian writers say, that the Romanina left Metastasio *erede di tutto il suo patrimonio*: "heir to all her patrimony." If by patrimony was meant an estate possessed by inheritance, and independently settled upon her at the time of her marriage, her testamentary dispositions are reconcileable to English ideas of law in such cases; though preferring the friend to the husband deviates somewhat from the general custom of our country. That the bequest was legal has never been doubted by Metastasio's biographers, who all speak of his renunciation in the highest terms of panegyric, as uncommonly disinterested, generous, and heroic. And the poet himself, as well as all Italy, regarded it as a noble sacrifice.

Whether Metastasio's connection with the Romanina was purely platonic, or of a less seraphic nature, we shall not attempt to determine. But the husband residing with them both at Naples and Rome, and the friendly manner in which the poet always mentioned him in his letters to the wife, and the openness with which he expressed his affliction in writing to him after her death, would, in England, be thought indications favourable to conjugal felicity. But a chaste actress or opera singer is still a more rare phenomenon in Italy than in Great Britain.

Yet though it is not thought absolutely necessary for the female singers of Italy to be vestals while single, or Lucretias when married, they find it convenient to have a nominal husband, who will fight their battles, contend with the first man, and impresario of an opera; and, occasionally, stand in the gap, as circumstances may require.

But whether the poet's friendship for Bulgarini, the husband, was pure and undissembled or not, his affliction for the death of his wife seems to have been unfeignedly deep and sincere. The following pathetic letter, written immediately after he had received the news of her decease, and of her testament in his favour, seems a faithful delineation of the state of his mind at this time, and to correspond with that goodness of heart, as well as those tender feelings and lofty ideas of rectitude, which appear in all his other writings, and which have ennobled the general tenor of his life.

"To signor Domenico Bulgarini.

"Oppressed by the afflicting news of the death of our poor Marianna, I know not how to begin this letter. The tidings are intolerable to me on so many accounts, that I can devise no means to diminish the acuteness of my sufferings; and, therefore, I trust you will not accuse me of want of feeling, if I am unable to suggest to you any consolation for your loss, as I have hitherto been utterly unequal to finding any for myself.

"The last disposition of the poor deceased in my favour aggravates the cause of my sorrow, and obliges me to give a public and incontestable proof of the disinterestedness of that friendship, which I professed to her while living, and which I shall preserve for her honoured memory to the last moment of my existence. Knowing, therefore, how much affection, kindness, and zeal, for the welfare of the poor Marianna, you have always manifested, I shall best shew my gratitude to her, by entirely renouncing, in your favour, all claim to her effects; not through pride, God preserve me from such ingratitude! but because it appears to be my duty, as an honest man and a Christian. The advantage which I shall still derive from this inheritance, even after renouncing it, will not be inconsiderable: as the knowing what was intended for me by the generous testatrix will be a lasting proof of her friendship; and the relinquishing it in your favour will be a proof of my disinterestedness with respect to her, and of my equity towards yourself. I am at present, thank God, in no need of such assistance, as I am rewarded beyond my merit; so that I shall not suffer by the sacrifice I make to you. Though I entangle you with no conditions in the renunciation which I enclose, yet I have some requests to make, and counsels to suggest to you.

"My first request is, that the relinquishing this claim may in no wise dissolve our friendship; but that, according to the wish of the poor Marianna, our correspondence may continue as entire as if she were still living; substituting you at all times, and in all places, for her representative.

"My second request is, that you will undertake the trouble of receiving the salaries of my three offices in Rome, and the transacting of my Neapolitan concerns, exactly in the same manner as was done by our incomparable Marianna; for which purpose, I send you proper powers. I write likewise to signor Tenerelli, at Naples, who will treat you in the same manner as signora Marianna herself; remitting to you, from time to time, whatever sums may be due to me from that quarter, continuing to my poor family the usual assignments and provision, if you shall chuse it, jointly with my brother.

"The advice which seems necessary for me to give you is, that you would assist the poor family of signor Francesco Lombardi, by every means in your power; and try by acts of charity to do every thing for them, which, in a similar situation, you would expect from them to you. I have specified in my renunciation some particulars in which you should assist them; but besides my unwillingness to involve you in trouble and difficulty, I am so certain of the goodness of your heart, that I have left all the merit of your benevolence towards them to the liberality of your own determination.

"In all things else, you are at full liberty to act as occasion, and your own prudence, shall suggest.

"At present, my mind is in too great perturbation for me to attempt giving you a plan for the regulation of your conduct. I shall only say, that it appears to me, as if you should dispose of all the effects you can spare, in order to raise a capital, and that you should live in a smaller house.

"I can

"I can think of no other testimony to offer you, at present, of my friendship and confidence. Be equally open in your correspondence, and consider my interests as your own, and me as your brother. I am unable now to write a longer letter: when my mind is more tranquil, I shall communicate to you such thoughts as may occur.

"In the mean time, love me, and endeavour to be comforted yourself. Be assured, if it were in my power, that I would try to contribute that to your consolation, which I am unable to receive myself."

In a letter to his brother Leopold, apologizing to him for the renunciation of the Romanina's intended kindness, he says, "I ought not to abuse the partiality of my poor deceased friend, at her husband's expence; and God, I trust, will permit me to prosper by some other means, for my integrity."

To a friend at Rome, on the subject of his affliction, he says, "I am now placed in the world as in a populous desert, and in that kind of desolation in which a man, if he were transported in his sleep to China or Tartary, would find himself in waking, among people of whose language, inclinations, and manners, he was quite ignorant."

If platonic affection can subsist in human nature, we may suppose it possible, perhaps, to have been realized between the poet and such a female friend as the Romanina; who, by what we can gather from Metastasio's letters, seems to have possessed a strong mind and great rectitude of heart.

The solemn manner in which so pious and moral a man as Metastasio says in his letter to a Roman friend, "In the midst of my gloomy imaginations, reason enough is left to tell me who, and what I am; but that is not sufficient to free me from affliction. May God, in whose hands are all events, turn this affliction to my benefit, and teach me by such a manifestation, what a vain hope it is to form systems of happiness, without his assistance." The late Mr. Mason, on reading this passage, regarded it as a proof that there had been nothing criminal between them.—"Such a man as Metastasio, writing to a friend, would have expressed in this place some compunction, at least he would not have invoked the Deity in such a solemn manner."

We have dwelt the longer on this incident in the poet's life, which places him, like Alcides, between virtue and vice, in hopes that a character, so exemplary during every other period of his existence, may, for the honour of humanity, descend spotless to posterity. In all other respects, his private virtues merit equal praise with his poetry, which has so long delighted the most polished and refined inhabitants of Europe.

Among the anecdotes, indeed, that were published after his decease, concerning the private life of our admirable bard, some peculiarities have been related, which seem too serious for ridicule, and from which we should be sorry, for his honour, and for the honour of human nature, not to be able to defend him. What a disgrace to practical virtue and benevolence would it be, to find a writer, whose works breathe the purest principles of virtue and morality, and whose life, during his long residence at Vienna, was unimpeachably innocent, and constant in the exercise of religious duties, to want, not only filial and fraternal affection, but even those common and laudable partialities for his kindred and countrymen, to which the most vulgar minds are naturally prone! It has been said with a degree of levity, perhaps more to enliven a period than from conviction, or a wish to degrade the poet's moral character, that "he refused to hear, and took pains not to know, whether he had, in his latter days, any relation left in the world." But in his correspondence, published by his executor signor Giuseppe Martinetz, aulic counsellor, and first keeper of the imperial library, there are letters to his father and brother, so full of filial and fraternal affection, as completely confute such hasty and unjust charges.

The year 1733 seems to have been extremely fertile in the Parnassian domains of our bard. Not only the operas of "l'Olympiade" and "Demofoonte," with the oratorio of "Giuseppe Riconosciuto, but his charming canzonet, "La Libertà," were all productions of this year. This celebrated canzonet, "Grazie agl' inganni tuoi," was first set by the poet himself, but soon after by all the great composers of Italy, as a Venetian ballad, a canzonet, a duo, and a cantata, to much more elaborate and fanciful music than that of the poet: yet his own melody, which has been composed more than seventy years, has still its merit; and, compared with airs of the same period and kind, is superior to most of them in elegant simplicity.

In 1734, besides his usual occupations, we find, by his letters, that he was obliged, in the greatest haste, to write an entertainment for music, to be performed by the archduchesses, and to instruct, direct, and assist them. "But in truth," he says, "it is a pleasure which no other can equal, to have such an opportunity of seeing and admiring the excellent qualities of these august princesses. I should not else have believed it possible to meet with such attention, docility, patience, and gratitude. Oh, how many people, of the sixteenth rank, have I known, who were not possessed of the thousandth part of the courtesy of these incomparable personages! They have acted and sung like angels, and it was truly sacrilege, that the whole world was not permitted to admire them; for the festival was extremely private, as none but the Vienna ladies of the highest rank were able to obtain admission, and even these were in masks. As a return for instructing their serene highnesses, I was presented with a gold snuff-box, of about fourscore hungheri (near 40*l.*) in weight; but the workmanship is of much more value."

This little dramatic poem was called "Le Grazie Vendicate," set by Caldara, and performed by the two archduchesses, Maria Teresa, afterwards empress-queen, and her sister Marianne, with another lady of the court.

In the year 1734 he produced, for the emperor's birthday, "La Clemenza di Tito."

It seems as if the character and court of Charles VI. had directed the muse of Metastasio to chuse a virtuous prince for the principal hero of most of the musical dramas that were represented in the imperial theatre. The emperor was a religious prince, and a rigid observer of decorum himself, which consequently kept licentiousness at a distance from his court. And the poet, naturally a friend to virtue and morality, seems to have gratified his own feelings, by conforming to the serious sentiments of his imperial patron.

In 1735 he produced, by command of the empress Elizabeth, a little opera, with three characters only, entitled "Le Cinesi," for the same two archduchesses and a lady of the court to perform, as an introduction to a Chinese ballet.

The same year he furnished "Il Palladio conservato," and "Il Sogno di Scipione," pieces written for the celebration of the emperor and empress's name-day. These were a kind of birth-day odes, but in a dramatic form, in which the praise was delicately disguised in a fable or allegory.

In 1736, his "Themistocles," set by Caldara, first appeared; but while this was performing, Metastasio had another task assigned him, the difficulties of which he frequently related to his friends, many years after.

To Betinelli, the printer, he writes: "I send you a copy of of the opera of 'Achille in Sciro,' which I have been obliged to write in eighteen days and a half, for the nuptials of the archducheſs Tereſa with the duke of Lorrain. Three months, which I uſed to allow myſelf for writing an opera, were never ſufficient to finiſh it to my mind: imagine whether it was poſſible to ſatisfy myſelf with this."

The admirable drama of "Ciro Riconoſciuto" was a production of this period.

It ſeems as if 1737 had been a ſabbatical year for our author and his muſe; for none of his poetical works bear that date, nor do any of his letters of that period appear in the collection.

In 1738 and 1739 he produced ſeveral ſmall occaſional pieces, chiefly for the archducheſſes to perform; which, though elegantly written, have not been of that general uſe to the reſt of Europe, which fell to the lot of moſt of his operas on a larger ſcale, for want of length and more characters.

In 1740, however, his dramatic muſe was better employed, and more propitious: for, beſides the opera of "Zenobia," and the oratorio of "Iſacco," he wrote "Il Natale di Giove," and the opera of "Attilio Regolo," for the birth-day of the emperor Charles VI.; but that prince dying before it had been repreſented, it was laid aſide, and not performed till 1750, when it was ſet by Haſſe, for the court of Dreſden.

The poet laments the death of his patron with great ſenſibility, in a letter to a friend. Indeed it was a calamity to all Europe, by the general war which immediately enſued.

This prince found in Metaſtaſio a man who encouraged and confirmed his love of virtue, decorum, and propriety; and Metaſtaſio found in his patron a prince ſuſceptible of receiving his recommendations of the moral and ſocial, as well as the heroic virtues. Indeed the poet and the patron ſeem to have been formed for each other.

Between the death of this emperor, in 1740, and 1745, when prince Charles of Lorrain, conſort to the empreſs-queen, was elected emperor, by the title of Francis I., the court of Vienna had little leiſure for being amuſed by the peaceful arts of poetry and muſic. We find, among the poet's works, but two complete dramas written during all that time: "Antigono," and "Ipermeſtra." One of theſe, "Antigono," was written expreſsly for the court of Dreſden. Both were ſet by Haſſe, who ranked high in the favour of Metaſtaſio, as a great compoſer and intelligent man.

Our author's poetical productions in 1746 conſiſt only of his two beautiful canzonette, "La Partenza," and "La Palinodia a Nice," thirteen years after he had ſo piouſly and elegantly thanked the gods for diſcovering to him her infidelities, in his "Grazie agl' inganni tuoi."

His correſpondence with the celebrated Farinelli began in 1747, to whom 38 of his letters are addreſſed, in the ſixth volume of his correſpondence, which ſeem the moſt affectionate and confidential in the collection. The poet and muſician were nearly of the ſame age. And having begun their career of fame and fortune together at Naples, in 1723, they, from that circumſtance, ever after called each other *Gemello*, or Twin, in their correſpondence, which laſted to the end of their lives. Many of the poet's letters were addreſſed to the great ſinger at Madrid, where, during two ſucceſſive reigns, he enjoyed the higheſt favour. See Farinelli.

The bleſſings of peace, after the ſeven years' war, revived at Vienna the innocent pleaſures of the lyric theatre; and in 1751 produced Metaſtaſio's beautiful opera of "Il Re Paſtore," which was followed, in 1752, by "l'Eroe Cineſe." Theſe were performed in the imperial theatre by perſons of the higheſt diſtinction, ſome of whom are ſaid greatly to have ſurpaſſed, in many particulars, profeſſed opera ſingers of the firſt rank.

In 1756, at the requeſt of his friend Farinelli, and with the permiſſion of his imperial patrons, he furniſhed the court of Spain with a new opera, entitled "Nitteti," which was brought on the ſtage there, with the utmoſt ſplendour and magnificence, under Farinelli's direction.

The laſt three operas written by Metaſtaſio, were "Il Trionto di Clelia," in 1762; "Remolo ed Erſilia," 1765; and "Il Ruggiero," in 1771; which were performed at three ſeveral places: the firſt at Vienna, on the delivery of Iſabella of Bourbon, firſt conſort of the emperor Joſeph II.; the next at Innebruck, on the marriage of the grand duke of Tuſcany with Maria, Infanta of Spain; and the laſt at Milan, on the nuptials of the archduke Ferdinand with Beatrice, princeſs of Modena, which terminated the dramatic labours of our admirable lyric bard.

His other poetical compoſitions, which are very numerous, conſiſt of oratorios, occaſional ſhort lyric pieces, hymns, and ſacred ſongs, cantatas, epithalamia, ſonnets, canzoni, complimentary verſes, &c., all replete with elegance, refined ideas, and every beauty of numbers which the Italian language ſo copiouſly can furniſh, and melody requires.

Among his proſe writings, the extracts from Ariſtotle's Poetics, and the Ars Poetica of Horace, are the principal; and theſe will long remain indiſputable proofs of his learning, good taſte, and perfect comprehenſion of the laws preſcribed by theſe great maſters, which he explains with the utmoſt clearneſs and practical utility; giving ſenſe to many paſſages that were thought obſcure and unintelligible.

In all his productions, religion, government, ſound policy, morals, manners, and even innocent prejudices, are ſo highly reſpected, that the moſt extreme delicacy never finds the leaſt ſentiment that can offend or alarm. His doctrines and practice in theſe particulars ſo perfectly agreed, that he conſtantly diſcountenanced in converſation all tendency to licence, diſreſpect, and diſputation on moral and ſacred ſubjects, though naturally cheerful, and pleaſantly metaphorical, in his converſation. This being his invariable practice during his long reſidence at Vienna, excited as much eagerneſs in travellers of all ranks to ſee and converſe with him, as the renown which he had juſtly acquired by his writings.

He was honoured with teſtimonies of reſpect and admiration from almoſt all the ſovereigns in Europe, where the Italian language and muſic were known, which he received with the utmoſt humility and gratitude.

Such were the delicacy and conſtancy of his friendly attachments and intercourſe, that death could only diſſolve them. The princeſs di Belmonte Pignatelli, the counteſs d'Althan of the ſame illuſtrious family, who knew and patroniſed him in his early youth; count Canale, baron Hagen, and count Perlas, who ſpent all their evenings with him at Vienna during their ſeveral lives; Farinelli, his correſpondent of 50 years duration, count Algarotti, and his brother, the advocate, Leopoldo, to whom 48 of his letters are extant; all theſe affections were habitual and deeply rooted in his heart.

His whole life appears to have been of that even tenour, which nothing but great accidents or public calamities could diſturb. His veneration and gratitude for his patroneſs, the empreſs queen, ſeem, during the laſt years of his life, to have been the ſtrongeſt paſſions to which he gave admiſſion in in his breast. When unfortunate in war, or on account of the sickness or death of any of her family, he was as much agitated as any of her most faithful and best subjects. But when her own life was endangered by disease, his equanimity and philosophy totally left him. Then yielding to the natural sensibility and tenderness of a heart, neither chilled by apathy, nor petrified by stoicism, he became a common man; not too stubborn for affliction, or too proud and obdurate for the impressions of calamity. The sickness of his brother, and death of the countess d'Althan, are likewise illustrations of this occasional sensibility.

His conversation was usually scientific, turning on new discoveries, new books, pleasing events, but rarely on calamity or unpleasant topics. By this means he kept his passions and affections in equilibrio, obtained prosperity in youth, and veneration in old age.

Though his longevity had extended to 84, yet his faculties were so entire, his person so free from any appearance of decrepitude, still possessing a florid countenance, and his accustomed eloquence, and playful language in conversation, that he was expected to have many years in store; but on the 1st of April, 1782, returning from his constant evening visit to count Perlas, he complained of a chilliness, eat very little at supper, and went to bed at his usual hour of 12 o'clock. "The next morning, (says mademoiselle Martinetz in her letter to Farinelli, giving him an account of his friend's decease,) he called for my elder brother, Giuseppe, and consulted him whether he had best rise and go to church, as he had intended, it being Easter Sunday; but was advised by him to remain in bed, as his pulse was very quick: an hour after the fever increased to such a degree, that it deprived him of speech, and he remained oppressed by a heavy lethargic sleep, which continued during two days, with short intervals, in which he was only able to take the medicines prescribed by Dr. Molinari, his physician. The fever diminished so much on the morning of the fifth day, that he became tranquil, spoke freely, conversed with some of his friends, who visited him, and was able, after dinner, to have the sacrament administered to him. You may imagine, sir, what great consolation this afforded us; but our hopes were of short duration, for at night the fever returned with such violence, that every day he became more lethargic, and baffled all the skill of the most able physicians, who met in consultation; so that on the 12th of April, between 11 and 12 o'clock at night, he finally, without much agony, expired."

Metastasio, lamented by all who knew or had heard of him at Vienna, was interred at the parish church of St. Michael, the 14th of April. The funeral rites were performed with splendour, by his grateful heir, signor Joseph Martinetz, in despite of the poet's injunctions, who had forbidden all kind of pomp. The inheritance of signor Martinetz consisted in a well-furnished habitation, a coach, horses, a great quantity of princely presents, a very ample and select collection of books, with a capital of 130,000 florins; from which, however, were to be deducted, 20,000 for each of the executor's sisters, and 3000 for each of his younger brothers.

The poet's attachment to the Martinetz family was of long standing. In the year 1730, on his arrival at Vienna, the first house in which he took up his residence, was that of signor Nicolò Martinetz, master of the ceremonies to the apostolic nuncio in that city. The eldest son of this gentleman he appointed his heir, jointly with his eldest sister, signora Marianna Martinetz, educated under his eye, and universally admired for her talents and accomplishments, particularly in music, not only as an excellent performer on the harpsichord, and an exquisite singer, but for her genius and abilities in composition, she was an elève of the great Dr. Haydn, who resided three years under the same roof with Metastasio during her musical studies; and had lessons in singing from the celebrated Porpora, who had many years before been the poet's own music master. The productions of mademoiselle Martinetz were communicated to, and approved by the greatest masters of Italy, and her name is inscribed as a member of the Philharmonic academy in Bologna and Mantua.

Signor Saverio Mattei, the most useful of Metastasio's biographers, though he rather gives advice to others, with loose and indigested materials, than a regular life of the poet, says, that "whoever wishes to acquire an exact knowledge of his customs, manners, way of life, opinions of himself and others; of his precision in fulfilling his duties, of the changes in his fortune, his application, and the different degrees of favour with which his several productions were at first received, their chronology, the influence they had on the taste of Italy, and on that of all Europe, with respect to the melodrama, or lyric stage, can only acquire such information by the perusal of his Letters."

"His Letters (says the abate Cristini, the most accurate and ample of all his biographers, and editor of the Nice edition of his works) will do honour to all Italy, while they discover his most intimate attachments, his most secret thoughts, his favourite opinions, and the history of a man who was all heart and all virtue."

"His genius (says signor Arteaga, Revol. del Theatro Mus. Ital.) may be compared to the goddess Chloris of the Greeks, who, in flying through the air, scattered roses wherever she went." The same grace, facility, and elegance of style appear in his prose, as have rendered his poetry so justly celebrated. Till we saw these Letters, we used to think that there was no Italian prose so easy to comprehend and construe, by young students in the language, as the dramas of Metastasio; but we are now convinced, that, in point of facility, the prose of our author is to his own poetry, what the prose of others is to their verse.

What renders these Letters infinitely more natural and satisfactory is, that, like the Epistolæ Familiares of Cicero, they were not written with the least view to publication; as is manifest by the lively complaints which he makes to his correspondents, who, for the gratification of their own vanity, had betrayed his confidence.

Few writers have been fortunate enough to enjoy the favour of the public so completely during their lives as Metastasio. But this felicity is not to be more ascribed, perhaps, to the excellence of his writings, than to his modesty, candour, and determination neither to give nor take offence by censuring the productions of others, or resenting the censures of his own. He seems to have seen, with due horror, the effects of literary war on the combatants.

That celebrity which he enjoyed so indisputably during life, was not diminished by his decease; his works are still in every hand: the philosopher, the courtier, the bigot, the man of the world, austere and gallant females, all equally read them, and all find them equally beautiful. His moral maxims are daily cited, and his productions are become the code of lovers. The setting and singing his verses, have rendered Pergolesi, Vinci, Jomelli, Sacchini, and Farinelli, Caffarelli, Pacchierotti, and Marchesi, as celebrated in all parts of Europe, as Corneille, Racine and Voltaire. Had his dramas been regular tragedies, written for declamation, without music, perhaps we should never have heard of them in England: but music being an universal language throughout Europe, they are certainly obliged to the composer and

singer

finger for a great part of their fame, at least out of Italy, notwithstanding the complaints of Metastasio himself, and the admirers of tragedy, who are inimical to music, that they have been injured by composers and performers. Particular operas, and perhaps, at some time or other, all his dramas, may have fallen into the hands of composers without genius, and singers without talents; but upon the whole, excellently written as are Metastasio's dramas, and exquisite as is the Italian language, it must be owned, that music has been the vehicle in which the operas of Metastasio have travelled into foreign countries. Cato, Regulus, Themistocles, Artaxerxes, Olimpiade, and Demofoonte, are allowed to breathe a true tragic spirit, even through the effeminate languor of lengthened tones and long divisions; but it is in the perusal, perhaps, not the vocal performance, that the force and beauty of Metastasio's dramatic scenes have been discovered out of Italy. When an air has been encored, it has not been for the beauty of the poetry, but the composition or performance of that air. It must be allowed, however, without the least deduction, that Metastasio's genius, good taste, and sound judgment, first achieved the difficult task of rendering so wild and incongruous a compound of seemingly heterogeneous ingredients and absurdities, as an *opera*, a rational entertainment.

Even the church has defended the morality of Metastasio's dramas. The ci-devant Jesuit, father Cordaro, in his eulogy of our poet, says, "I well know that he has been accused by some of having brought the passion of love too forward in his dramas, at the risk of seducing and enervating the heart and virtue of the hearers. How shall we defend him from this charge? He would certainly have done better, if he could have confined himself to the love of glory, and of our country, in displaying the virtues of valour, fidelity, and constancy, without meddling with the follies of lovers. But there are certain noble affections, concerning which, the vulgar have but little knowledge, and less taste. On the contrary, every one understands love; and without that seasoning every representation, at present, seems insipid. It is the predominant passion of the times. He was perhaps necessitated to comply with it; but with what precaution and reserve! Has an unchaste word ever escaped him? Or an idea that is not strictly within the limits of the most perfect delicacy? This may be said of his secular dramas taken from profane story; but his sacred dramas are not only exempt from blame with respect to the passion of love, but sufficiently pure in morals and doctrine, to serve as correctives to whatever the most morose critics may object to his productions for the stage."

The chronology and *moral object* of each drama is indicated in the English Memoirs of his Life and Writings, vol. iii. p. 316. &c.

We dare extend this article no farther. Our biographical articles should doubtless, in general, be confined to the battles of heroes, and books of the learned; but Metastasio's private character, meriting as much display as his public productions, we could not in our sketch of his life help stopping on the road to look about us, and admire the beautiful views which a life well spent affords.

METASTASIS, in *Medicine*, μεταστασις, signifies a translation or transition of disease from one part of the body to another, the part first affected recovering its natural functions at the time when the other begins to be diseased.

These transitions of disease have been noticed from the earliest history of the practice of medicine; and the writings of Hippocrates abound with instances of the fact, and with practical precepts, deduced from a careful observation of the consequences that ensue under the various circumstances of their occurrence. The older writers, who ascribed all diseases to the existence of a morbid matter, which, in whatever part it prevailed, gave rise to peculiar local symptoms, readily explained these instances of metastasis, upon the supposition that the morbid matter was substantially translated from the part first diseased to the seat of the new affection: indeed, this translation of the disease was deemed by them one of the proofs of the existence of a *materies morbi*. But we have already shewn, at some length, that the existence of such a morbid matter, as the efficient cause of diseases, is purely a gratuitous supposition, which more accurate investigation has exploded; and that the fact of the transition of disease by what has been called *metastasis*, although not easily explained upon any hypothesis, is as satisfactorily accounted for on the principle of sympathy, through the medium of the nervous system, which experiment has demonstrated, as upon the notion of an actual transference of morbid matter, which is hypothetically assumed. See HUMORAL *Pathology*.

It is scarcely necessary here to point out examples of the metastasis of diseases, which are universally recognised: such are the severe attacks of disorders in the stomach, when the inflammatory gout suddenly disappears from the extremities; the occurrence of diarrhœa or dysentery, upon the sudden retrocession of the measles, or other extensive eruption on the skin; the appearance of epileptic convulsions upon the cessation of the hæmorrhoidal, or other habitual discharge; the inflammation of the testes in men, or of the mammæ in women, which ensues, when that of the parotid glands in the disease called *mumps*, suddenly disappears; and other cases of a similar nature.

The transition by metastasis, however, is only one of several modes in which diseases are converted into each other. Of these we have already described the varieties in a former article, to which we refer the reader. See CONVERSION *of Diseases*.

METASTASIS, Μεταστασις, *Remotio*, in *Rhetoric*, is used for the removing the blame from the person accused to another person, or laying it upon something as a cause. Thus, Adam's excusing himself by blaming Eve, is an example of the former; and the laying the crime of drunkenness upon the wine, is an instance of the latter.

METASTELMA, in *Botany*, from μεῖα, signifying *a change*, and στελμα, *a crown*, because the usual crown of the stamens being wanting, its place is supplied by a five-toothed appendage to the mouth of the corolla. Brown in Wern. Trans. v. 1. 52.—Class and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juss. *Asclepiadeæ*, Brown.

Ess. Ch. Corolla bell-shaped; its mouth crowned with five prominent teeth, opposite to the sinuses, running down the tube. Crown of the stamens none. Anthers tipped with a membrane. Masses of pollen compressed, attached by their taper points, pendulous. Stigma pointless. Follicles. . . .

M. *parviflorum*. (Cynanchum parviflorum; Swartz Ind. Occ. 537. Willd. Sp. Pl. v. 1. 1258. Periploca scandens, nummulariæ foliis, flore albo; Plum. Ic. 209. t. 215. f. 1.)—Native of wild mountainous thickets in the West Indies, in various islands of which it was gathered by Plumier, Swartz, Masson, and Von Rohr. The *stem* is somewhat shrubby, twining to a great extent, subdivided, slender, bluntly quadrangular, smooth like every other part of the herbage; its branches thread-shaped, opposite, spreading, and twining. *Leaves* about an inch long, opposite, distant, stalked, ovate, entire, thin, smooth on both sides, with one rib, and several transverse veins, tipped with a minute, rigid, awl-shaped point. *Umbels* nearly sessile between the footstalks, of about six or eight small, stalked, greenish-white *flowers*, whose segments are acute, finely downy, thickened at the edges, and reflexed. Mr. Brown complains of the inaccuracy of Dr. Swartz's description of the crown of the flower, and we have also to remark that the umbels are, as the former truly says, between the footstalks, not axillary; and the leaves have a very conspicuous rib, as well as numerous veins. The name was given by Dr. Solander, from whom, as well as Dr. Swartz, we have specimens.

METATARSIUS, in *Anatomy*, the abductor minimi digiti pedis. See Abductor.

METATARSUM, in *Natural History*, a name given by authors to a sort of stone supposed to represent a human foot. See Metapedium.

METATARSUS, in *Anatomy*, one of the divisions of the foot. See Extremities.

METATEPEC, in *Geography*, a town of Mexico, in the province of Guasteca; 50 miles S. of Panuco.

METATHESIS, Μεταθεσις, formed of μετα, *trans*, and θεσις, *position*, *transposition*, a grammatical figure, whereby letters or syllables of a word are transposed, or shifted out of their natural situation; as *Evandre* for *Evander*; *I pre* for *prei*.

Metathesis, a word used by medical writers for a change of place in such humours, or other diseased parts, as cannot be absolutely removed or sent off. Thus a metathesis of a cataract is a depression thereof, so that it no longer shuts out the light.

METATOR, among the Romans, a quarter-master. Out of every legion a tribune, and some centurions, were appointed to go before the army, in order to choose a place for a camp, and assign and mark out quarters to each legion.

METAWAUMKEAG, in *Geography*, a large northerly branch of the river Penobscot, in America.

METCHICOT, a lake of Canada. N. lat. 50° 22'. W. long. 88° 30'.

METCHIGAMIAS, a long narrow lake, or rather dilatation of the northern branch of the river St. Francis, in Louisiana, which falls into the Missisippi from the N.W. about four miles above Kappas Old Fort.

METE, a small island in the Arabian sea, near the coast of Adel. N. lat. 11° 10'. See Babelmandeb.

METEARA, a town of Hindoostan, in Bahar; 23 miles S.E. of Saseram.

METECAL, or Metical, in *Commerce*, a weight for gold, silver, and diamonds, in the Levant. At Aleppo it is used for weighing pearls and ambergris, and is $1\frac{1}{2}$ drachm, or 73 English grains. At Damascus, silver is sold by the ounce of 10 pesi, or $6\frac{2}{3}$ metecalli, weighing 19 dwt. 4 gr. English troy. At Smyrna, gold and silver lace is sold by the metical of $1\frac{1}{2}$ drachm avoirdupois, or 72 grains troy weight, very nearly. See Weights.

METEGAVEL, in our *Old Writers*, a tribute or rent paid in victuals, which was a thing used in this kingdom, as well with the king's tenants as others, till the reign of king Henry I.

The word is Saxon, *metagavel*; *i. e. cibi gablum, seu vectigal.*

METELAR, in *Geography*, one of the Laccadive islands. N. lat. 12° 18'. E. long. 72° 25'.

METELE, a town of Lithuania, in the palatinate of Troki; 36 miles N. of Grodno.

METELEN, a town of Germany, in the bishopric of Munster; 19 miles N.W. of Munster. N. lat. 52° 14'. E. long. 7° 10'.

METELIN. See Mitylene.

METELINOS, a town of the island of Samos; 2 miles N.E. of Cora.

METELLUS, Quintus Cæcilius, in *Biography*, the son of L. Cæcilius Metellus Calvus, was raised to the consulate, during the Jugurthine war, with M. Junius Silanus, in the year B.C. 109. On casting lots for the consular provinces, that of Numidia fell to Metellus, who made immediate preparations for retrieving the honour of the Roman arms, which had lately fallen into disgrace through the successes of Jugurtha. He was extremely careful in the selection of the officers to serve under him, and chose, among others, of known military talents, the famous Marius, who, for want of interest, had for some time remained unemployed at Rome. Having restored order and discipline in his army, he marched into the centre of Numidia, where he defeated and dispersed the whole force commanded by Jugurtha in person. When the consular year was ended, the command was continued to Metellus as pro-consul, and he pursued the plan of ruining the country of Jugurtha, and cutting off his resources. At length the circumstances of the Numidian obliged him to enter into a treaty with Metellus, by which he delivered up all his elephants, a number of horses and arms, and all the deserters from the Roman army. The latter, to the disgrace of the conqueror, were put to death, with great cruelty. Jugurtha took the first opportunity of appearing again in arms, and the people rose upon a Roman garrison, and massacred the whole, excepting the commander Turpilius. Metellus soon recovered the place, brought Turpilius to a court martial, and caused him to be put to death, on account of which he underwent the keenest remorse: having been influenced in his decision rather by popular clamour than by the strict rules of justice. Marius had been a leading actor in the condemnation of Turpilius, and triumphed in the consequences which it had upon the mind of Metellus, whose character with the people he endeavoured to injure. The third year of his command was going on, and nothing decisive had been effected. Of this his rival, Marius, made a handle, and by his representations to the people was able, not only to procure his own election to the consulate, but to obtain a decree for his superseding Metellus in the conduct of the Numidian war. Metellus deplored his hard fate with tears. He refused to see his rival; delivered up his army by a lieutenant, and immediately embarked for Rome. He was received with great honour by his friends and partizans, who obtained for him the honour of a triumph. Being charged with peculation by a tribune, he would have produced his books in his own justification; but the Roman knights who sat as his judges refused to examine his accounts, declaring that they considered the whole tenor of his life as a sufficient testimonial of his innocence. Having passed with honour through his military career, there remained a trial of his civic virtue and firmness, in which he obtained equal credit. In the year B.C. 100, the most violent measures were carried on by the popular leaders; and the tribune Apuleius Saturninus having prepared an Agrarian law, procured a clause to be previously passed, that the senate would swear to confirm whatever the people should enact. Metellus opposed the proposition; the senate, to a man, joined in a similar opposition. Marius, who had led them to this determination, by pretending to entertain the same sentiments, soon retracted, and took the oath; all the senators, excepting Metellus, followed his example. Metellus persisting in his resolution was condemned to banishment. His friends offered to oppose this act of injustice, but he declared that not a drop of blood should be spilt on his account. He said, "either the state of public affairs will change, and I shall be recalled; or, if they remain as as they are, I ſhall be better off any where than at Rome." He then paſſed over to Rhodes, or Smyrna, where he paſſed his time in the ſtudy of philoſophy. In the following year, a decree was paſſed by a great majority for his return: the news was brought to him while he was aſſiſting at ſome public games, and though he was informed that the packet contained pleaſing intelligence, he would not open it till the ſpectacle, perhaps a religious ceremony, was over. On his return to Rome he was met at the gates by all the perſons of diſtinction in the city, and was accompanied to his houſe by great crowds of people, and at the next conſular election the public eſteem for him was ſhewn by accepting his recommendation of one of his own name and family. After this, we hear no more of this worthy man.

METEMPSYCHI, in *Church Hiſtory*, heretics, who, in imitation of the Pythagoreans, maintained the tranſmigration of ſouls. See METEMPSYCHOSIS.

METEMPSYCHOSIS, Μετεμψυχωσις, formed of μετα, *beyond*, and εμψυχω, *I animate*, or *enliven*, in the *Ancient Philoſophy*, the paſſage or tranſmigration of the ſoul of a man, after death, into the body of ſome other animal.

Pythagoras and his followers held, that, after death, men's ſouls paſſed into other bodies, of this or that kind, according to the manner of life they had led. If they had been vicious, they were impriſoned in the bodies of miſerable beaſts, there to do penance for ſeveral ages; at the expiration whereof, they returned afreſh to animate man. But if they had lived virtuouſly, ſome happier brute, or even a human creature, was to be their lot.

What led Pythagoras to this opinion was, the perſuaſion he had, that the ſoul was not of a periſhable nature: whence he concluded, that it muſt remove into ſome other body upon its abandoning this. According to Empedocles, human ſouls, in the courſe of the tranſmigration to which they are liable, may inhabit not only different human bodies, but the body of any animal or plant. Lucan treats this doctrine as a kind of officious lie, contrived to mitigate the apprehenſion of death, by perſuading men, that they only changed their lodging; and only ceaſed to live to begin a new life.

Reuchlin denies this doctrine; and maintains, that the metempſychoſis of Pythagoras implied nothing more than a ſimilitude of manners, deſires, and ſtudies, formerly exiſting in ſome perſon deceaſed, and now revived in another alive. Thus, when it was ſaid, that Euphorbus was revived in Pythagoras, no more was meant than that the martial virtue, which had ſhone in Euphorbus at the time of the Trojan war, was now, in ſome meaſure, revived in Pythagoras, by reaſon of the great reſpect he bore for the athletæ. For thoſe people wondering how a philoſopher ſhould be ſo much taken with men of the ſword, he palliated the matter, by ſaying, that the ſoul of Euphorbus, *i. e.* his genius, diſpoſition, and inclinations, were revived in him. And this gave occaſion to the report, that Euphorbus's ſoul, who periſhed in the Trojan war, had tranſmigrated into Pythagoras.

Ficinus aſſerts, that what Plato ſpeaks of the migration of a human ſoul into a brute, is intended allegorically, and is to be underſtood only of the manners, affections, and habits, degenerated into a beaſtly nature by vice. Serranus, though he allows ſome force to this interpretation, yet inclines rather to underſtand the metempſychoſis of a reſurrection.

Pythagoras is ſaid to have borrowed the notion of a metempſychoſis from the Egyptians (ſee EGYPT); others ſay, from the ancient Brachmans. It is ſtill retained among the Banians, and other idolaters, of India and China; and makes the principal foundation of their religion. (See BRACHMANS, BANIANS, and GENTOOS). So extremely are they bigotted to it, that they not only forbear eating any thing that has life, but many of them even refuſe to defend themſelves from wild beaſts. They burn no wood, leſt ſome little animalcule ſhould be in it; and are ſo very charitable, that they will redeem from the hands of ſtrangers any animals that they find ready to be killed. See PYTHAGOREANS.

METEMPTOSIS, from μετα, *poſt*, and πιπτω, *cado*, *I fall*, a term in *Chronology*, expreſſing the ſolar equation, neceſſary to prevent the new moon from happening a day too late.

By which it ſtands contradiſtinguiſhed from *proemptoſis*, which ſignifies the lunar equation, neceſſary to prevent the new moon from happening a day too ſoon.

The new moons running a little backwards, that is, coming a day too ſoon at the end of three hundred and twelve years and a half; by the proemptoſis, a day is added every three hundred years, and another every two thouſand four hundred years; on the other hand, by the metemptoſis, a biſſextile is ſuppreſſed each one hundred and thirty-four years; that is, three times in four hundred years. Theſe alterations are never made but at the end of each century; that period being very remarkable, and rendering the practice of the calendar eaſy.

There are three rules for making this addition, or ſuppreſſion, of the biſſextile day, and, by conſequence, for changing the index of the epacts. 1. When there is a metemptoſis without a proemptoſis, the next following, or lower index, muſt be taken. 2. When there is a proemptoſis without a metemptoſis, the next preceding or ſuperior index is to be taken. 3. When there are both a metemptoſis and a proemptoſis, or when there is neither the one nor the other, the ſame index is preſerved. Thus, in 1600, we had D; in 1700, by reaſon of the metemptoſis, C was taken; in 1800, there were both a proemptoſis and a metemptoſis; ſo the ſame index was retained. In 1900, there will be a metemptoſis again, when B will be taken, which will be preſerved in 2000, becauſe there will then be neither the one nor the other. This is as far as we need compute for it: but Clavius has calculated a cycle of 301,800 years; at the end of which period, the ſame indices return in the ſame order. See EPACT.

METEOR, from μετεωρος, *high*, *ſublime*, is a general term uſed to ſignify the tranſient, fiery appearances in the heavens; ſuch as are denoted by the more particular names of *ſhooting ſtars*, *globes of fire*, *ignes fatui*, *aurora borealis*, &c. The word is uſed by ſome writers to ſignify all the various phenomena of the atmoſphere, as *clouds*, *rain*, *hail*, &c. in which caſe meteors are divided into *fiery* and *watery*; but this laſt diſtinction is adopted by few. We ſhall under this head make a few obſervations upon the fiery meteors, or thoſe more generally deſignated by the name meteor, and leave the other to be conſidered under the article METEOROLOGY.

The phenomena called *ſhooting* or *falling ſtars* have been ſeen by every one, as theſe meteors are viſible in greater or leſs numbers every clear night; they need not therefore be particularly deſcribed. Theſe meteors are ſo very tranſient, not often exceeding one or two ſeconds in duration, that they afford no opportunity for obſervations by which their altitude can be determined with accuracy, and conſequently we are in a great meaſure ignorant of their height. If a few intelligent perſons were to agree to make the beſt obſervations they could on the altitudes of theſe meteors ſome ſuitable evening, ſuppoſing the obſervers to be ſtationed at the diſtance of ten, twenty, or more miles from each other, and to have their watches, &c. duly adjuſted, it is very probable that data might be obtained to ascertain the height of these meteors, within certain limits at least.

Though the general appearance of these meteors is that of stars shooting or falling, yet they occasionally are observed of great magnitude and comparatively of long duration, sometimes almost as large as the moon, and move through a celestial arc of 100°, more or less. As an instance of this kind we may take the great meteor of August 18th, 1783, an account of which was given in the Philos. Transact. 1784, by the late Mr. Cavallo, from his own observations, and those of some intelligent friends who happened to be with him, at Windsor. "On the evening of the 18th of August 1783, we were standing upon the N.E. corner of the above-mentioned (Windsor) terrace. The weather was calm, and agreeably warm; the sky was serene, excepting very near the horizon, where a haziness just prevented the appearance of the stars. A narrow, rugged, and oblong cloud stood on the N.W. side of the heavens, reaching from the extremity of the haziness, which rose as high as 18 or 20 degrees, and stretching itself for several degrees towards the east, in a direction nearly parallel to the horizon. It was a little below this cloud, and consequently in the hazy part of the atmosphere, about the N. by W. half W. point of the compass, that this luminous meteor was first perceived. Some flashes of lambent light, much like the aurora borealis, were first observed on the northern part of the heavens, which were soon perceived to proceed from a roundish luminous body, nearly as big in diameter as the semidiameter of the moon, and almost stationary in the above-mentioned point of the heavens. It was then about 25 minutes after nine o'clock in the evening. The ball at first appeared of a faint bluеish light, perhaps from being just kindled, or from its appearing through the haziness; but it gradually increased its light, and soon began to move, at first ascending above the horizon in an oblique direction towards the east. Its course in this direction was very short, perhaps of five or six degrees; after which it directed its course towards the east, and, moving in a direction nearly parallel to the horizon, reached as far as the S.E. by E. point, where it finally disappeared. The whole duration of the meteor was half a minute, or rather less; and the altitude of its track seemed to be about 25 degrees above the horizon. A short time after the beginning of its motion, the luminous body passed behind the above-mentioned small cloud, so that during this passage we observed only the light which was cast in the heavens from behind the cloud, without actually seeing the body from which it proceeded for about the sixth or at most the fifth part of its track; but as soon as the meteor emerged from behind the cloud, its light was prodigious. Every object appeared very distinct; the whole face of the country, in that beautiful prospect before the terrace, being instantly illuminated. At this moment the body of the meteor appeared of an oblong form; but it presently acquired a tail, and soon after it parted into several small bodies, each having a tail, or elongation; and all moving in the same direction, at a small distance from each other, and very little behind the principal body, the size of which was gradually reduced after this division. In this form the meteor moved as far as the S.E. by E. point, where the light decreasing rather abruptly, the whole disappeared.

"During the phenomenon no noise was heard by any of our company, excepting one person, who imagined to have heard a crackling noise, something like that which is produced by small wood when burning. But about ten minutes after the disappearance of the meteor, and when we were just going to retire from the terrace, we heard a rumbling noise, as if it were of thunder at a great distance, which in all probability was the report of the meteor's explosion; and it may be naturally imagined that this explosion happened when the meteor parted into small bodies, *viz.* at about the middle of its track.

"Now if that noise was really the report of the explosion which happened at the above-mentioned place; the distance, altitude, course, and other particulars relating to this meteor, must be very nearly such as are expressed in the following list; they being calculated with mathematical accuracy upon the preceding particulars, and upon the supposition that sound travels at the rate of 1150 feet *per* second. But if the noise we heard was not that of the meteor's explosion, then the following results must be considered as quite useless and erroneous.

Distance of the meteor from Windsor castle - - -	130 miles
Length of the path it described in the heavens - - -	550 miles.
Diameter of the luminous body, when it came out of the clouds -	1070 yards.
Its height above the surface of the earth - - -	56½ miles.

The explosion must have happened perpendicularly over Lincolnshire."

The above account was written the day after the appearance of the meteor; and in his Natural Philosophy this author farther observes, "Those accounts which were sent from various parts of this island, as also from the continent, confirmed, as nearly as can be expected, the above-mentioned results respecting its size, velocity, elevation, and explosion over Lincolnshire; but this meteor must have certainly had its origin much farther north than we imagined; and indeed, on account of the intervening cloud, it was impossible for us to perceive it at an earlier part of its course. It is also probable that it must have gone or terminated at a much greater distance than it appeared to us; for as its light diminished until it vanished, we must naturally have lost sight of it sooner than those who stood farther south on the continent. The various accounts seem to establish, that its course commenced beyond the northern extremity of this island, probably somewhere over the northern ocean. It passed a little westward of Perth, and perhaps a little eastward of Edinburgh; it proceeded over the south of Scotland, Northumberland, the bishopric of Durham, Yorkshire, Lincolnshire, over which it seemed to have deviated gradually to the westward, and in the course of that deviation to have suffered the bursting or partition. It then passed over Cambridgeshire, Essex, and the straits of Dover, entering the continent probably not far from Dunkirk, where, as well as at Calais and Ostend, it was thought to be vertical. It was seen at Brussels, Paris, Nuits in Burgundy, and, it is said, even at Rome. Upon the whole, it must have described a track upwards of 1000 miles in about half a minute; an astonishing rate of going, vastly swifter than the motion of sound." Vol. iv. p. 363.

In corroboration of the general accuracy of the above account, the author of this article may add his testimony, having been a witness of the meteor nearly during the whole of its apparition from Kendal in Westmoreland, a place, as it should seem from the above account, situated near to the middle of the meteor's track. The meteor, as seen from thence, rose near the N.W., moved nearly in the direction of the magnetic meridian, and disappeared in the S.E. The apparent velocity was least at first and at last, and greatest during the middle or highest part of the track; but the variation was not more than what would arise from a really uniform velocity,

velocity, owing to the optical illusion in such case. The greatest altitude of the meteor seemed to be very nearly 50°, and its duration was about half a minute, more or less; its altitude, when first seen, might be about 15° or 20°, and nearly the same at its disappearance. The sky was quite clear, except a haziness in the S.E. horizon; the twilight was considerable; yet the first attention to the meteor arose from observing the moving shadow of a window frame. No subsequent report was heard; but this might be from the attention being at that time otherwise engaged. From a comparison of observations at different places, its height was estimated to be about 60 miles.

Upon the whole it may be pretty safely concluded, that the height of this meteor was not less than 50, nor more than 60 miles above the earth's surface; and that its motion was nearly in a horizontal direction during the whole of its course.

From the general resemblance of the small meteors or shooting stars to the large globes of fire, except in size and duration, it can scarcely be doubted that they are of the same nature. Whatever hypothesis may be laid down to explain the one, must be expected to apply to the other; and if the results of the recent observations and investigations respecting the stones fallen from the atmosphere are to be credited, these last phenomena are intimately connected with the former.

Dr. Halley conjectured, that a stratum or train of inflammable vapour, gradually raised from the earth, and accumulated in an elevated region, suddenly took fire at one end, and burning like a train of gunpowder, exhibited the meteoric phenomena. (Philos. Trans. vol. 30. N° 360.) But this notion appears to have been entirely laid aside, as altogether untenable.

In later times, since the discoveries in electricity, meteors have been very generally ascribed to that agent. There seem, however, insuperable difficulties in explaining their phenomena upon electrical principles. The air, at the height of fifty miles, is probably 30,000 times more rarified than at the earth's surface; in such circumstances, we are almost certain that the electric fluid would either not pass at all, or pass in a very thin, attenuated state, so as to be far from exhibiting that densely luminous appearance which accompanies all the meteors in the form of balls. But admitting that large dense balls of electric fluid could be formed and conveyed through these high regions of the atmosphere, we should still be at a loss for materials to form those ponderable metallic masses which seem occasionally to be precipitated upon the surface of the earth, after the appearance of the meteor.

Professor Clap, late president of Yale college, in New England, in his theory of meteors, supposes them to be "terrestrial comets, revolving about the earth in the same manner as the solar comets revolve about the sun. That moving in very excentric orbits, when in perigee, they pass through the atmosphere, are highly electrified, and consequently become luminous. As they approach their lower apside, their electricity is discharged, the body disappears, and a report is heard. This being admitted, it is not strange that, by the violence of the shock, portions of the meteor should be thrown to the earth, while the main body, not sensibly affected by so small a loss, continues to move on in its orbit, and of course ceases to be luminous." Silliman on Meteoric Stones, American Philos. Trans. vol. 6. p 335.

In the Philos. Transact. 1784, Dr. Blagden has given "An account of some late fiery meteors; with observations." He considers the meteors under the following heads, in all of which he makes various appropriate observations. 1. Their general appearance. 2. Their path. 3. Their shape or figure. 4. Their light and colours. 5. Their height. 6. Their noise. 7. Their size. 8. Their duration: and, 9. Their velocity. In discussing the opinions of philosophers on the subject, he refers to professor Clap's, as follows: "A strong objection to this hypothesis of permanent revolving bodies, is derived from the great number of them there must be to answer all the appearances. Such a regular gradation is observed from these large meteors, which strike all beholders with astonishment, and occur but rarely, down to the minute fires, called shooting stars, which are seen without being regarded in great numbers every clear night, that it seems impossible to draw any line of distinction between them, or deny that they are all of the same nature. But such a crowd of revolving bodies could scarcely fail to announce their existence by some other means than merely a luminous train in the night, as for instance, by meeting or jostling sometimes near the earth, or by falling to the earth in consequence of various accidents; at least one might expect they would be seen in the day-time, either with the naked eye, or telescopes, by some of the numerous observers who are constantly examining the heavens. Another argument of great weight against the hypothesis that fire-balls are terrestrial comets, is taken from the great velocity. A body falling from infinite space towards the earth, would have acquired a velocity of no more than seven miles a second, when it came within 50 miles of the earth's surface; whereas these meteors seem to move at least three times faster. And this objection, if there be no mistake in regard to the velocity of the meteors, as I think there is not, absolutely oversets the whole hypothesis." Page 223.

Dr. Blagden proceeds to explain these meteors on the hypothesis that they are electrical phenomena. His arguments are; 1st. From the great rapidity of their motion, which seems to exceed any other we are acquainted with besides that of electricity. 2dly. From certain electrical phenomena, which sometimes accompany these meteors; and 3dly. From the connection which they have with the aurora borealis, or northern lights. These last are well known to regard the magnetic meridian; and most of the great meteors have been observed to move in a direction nearly coincident with the same meridian. Upon this head he observes; "the tendency towards the magnetic meridian, however, seems to hold good only with regard to the largest sort of fire-balls; the smaller ones move more irregularly, perhaps because they come further within the verge of our atmosphere, and are thereby more exposed to the action of extraneous causes. That the smaller sort of meteors, such as shooting stars, are really lower down in the atmosphere, is rendered very probable by their swifter apparent motion; perhaps it is this very circumstance which occasions them to be smaller, the electric fluid being more divided in more resisting air. But as these masses of electricity, which move where there is scarcely any resistance, so generally affect the direction of the magnetic meridian, the ideas which have been entertained of some analogy between these two obscure powers of nature, seem not altogether without foundation." P. 230.

Dr. Blagden concludes, that there are *three* regions of the atmosphere, distinguished by electrical phenomena peculiar to each. 1st. The lowest region, in which the phenomena of thunder and lightning occur. 2dly. The middle region, where the fire-balls and shooting stars are observed; and, 3dly. The highest region, where the aurora borealis displays a peculiar kind of electric agency.

Though many of the arguments which Dr. Blagden has advanced in favour of the hypothesis of electricity being the origin of meteors, are of considerable weight, yet the circumstances which have since occurred respecting the falling of of ſtones from the ſky, effectually remove one of his objections to the reception of profeſſor Clap's hypotheſis; namely, that of the meteors not "falling to the earth in conſequence of various accidents," and at the ſame time they riſe up againſt the electrical hypotheſis; unleſs indeed another be attached to it, that electricity condenſes and fuſes the earthy and metallic exhalations in the atmoſphere, which are thus precipitated to the earth's ſurface in greater or leſs portions. The other great objection to Clap's hypotheſis, that of the velocity of fire-balls being greater than is conſiſtent with a body revolving round the earth, however, remains in full force, except it can be ſhewn that the velocity of meteors has been much overrated. From the law of gravitation it is demonſtrable, that the velocity of a body revolving round the earth cannot, even when in perigee, and near the ſurface of the earth, be leſs than five, nor more than ſeven miles *per* ſecond. Hence, then, if the velocity of a meteor exceeds ſeven miles *per* ſecond, it cannot be a body revolving in an orbit round the earth. It does not appear, however, to be ſatisfactorily aſcertained that the velocity of fire-balls exceeds ſeven miles *per* ſecond. It is not perhaps going beyond probability to ſay, that no obſerver ſaw the great meteor of Aug. 18th, 1783, for more than an extent of 200 miles; as a proof, it may be remarked that the burſting of the meteor, ſaid to have taken place over Lincolnſhire, was not obſerved at Kendal, though the diſtance from the neareſt point, or that of greateſt apparent altitude, was not more than 100 miles. Now if the meteor took 30 ſeconds to move 200 miles, it gives $6\frac{2}{3}$ miles *per* ſecond; which is within the required limits. And, farther, let thoſe who ſaw the meteor paſs nearly through the zenith, endeavour to eſtimate the time it ſeemed to take in paſſing through an arc of 10°, or let the like obſervation be made upon a ſhooting ſtar. Perhaps few, if any, will be found to inſiſt upon the time being ſo little as one ſecond; at leaſt the writer of this article is not inclined to adopt the affirmative from his own obſervation. But 10° in one ſecond would correſpond only to eight miles of velocity, at the height of 50 miles above the earth's ſurface. It may therefore perhaps be ſtill deemed problematical, whether the velocity of either the larger or ſmaller meteors ever exceeds ſeven miles *per* ſecond; as alſo whether it ever falls ſhort of five miles *per* ſecond.

Upon the whole, the hypotheſis of fire-balls being ſomething of the nature of comets, that is, bodies revolving around the earth in excentric orbits, appears in the preſent ſtate of the ſcience to be as probable as any other. The light and heat acquired in paſſing through the perigee might be variouſly accounted for; but it would be premature to enter into a diſquiſition on this head, as long as ſuch doubts remain reſpecting the real velocity of this ſort of meteors. See Balls *of Fire* and Falling *Stones*.

Ignis fatuus is the name of a luminous meteor, ſaid to be ſeen occaſionally in the night, hovering over moiſt ground, and about church-yards. Though it is ſtated by writers to be a common meteor, we find few authentic accounts of its nature and appearance; and ſome accounts are evidently mixed with ſuperſtitious notions reſpecting the origin of the meteor, and particularly with regard to its effects in miſleading travellers. See Ignis *fatuus* for more on this head.

One of the moſt ſplendid and moſt ſurpriſing of the luminous meteors is the *aurora borealis*, or *northern lights*. An account of this meteor may be ſeen under the article Aurora *Borealis*; but as ſome of the lateſt, and perhaps the moſt accurate obſervations on theſe ſtriking phenomena, have been omitted in that account, it will be proper to introduce them here. The obſervations are thoſe of Mr. Dalton, publiſhed in his Meteorological Eſſays, 1793. This diligent obſerver reſided in the north of England (at Kendal), during a period when theſe phenomena were very frequent; namely from 1786 to 1793. The aurora borealis has ſeldom appeared ſince that period; and it ſhould ſeem, from the hiſtory of this meteor, that it is one in ſome way ſubject to periodical apparition.

Mr. Dalton has given the times and appearances of the aurora borealis, ſome of them deſcribed minutely, with accompanying obſervations on the variation of the magnetic needle. It ſeems the number of the phenomena ſeen at Kendal and Keſwick, was as under:

		Number of Auroræ Boreales.
1786	———	16
1787	———	27
1788	———	53
1789	———	45
1790	———	36
1791	———	37
1792	———	23

From ſuch a number of obſervations, and from thoſe previouſly made by others, to be found in various philoſophical works, the author was enabled to generalize the phenomena of the aurora borealis. He obſerves, "the appearances of the *aurora* come under four different deſcriptions. Firſt, a *horizontal light*, like the morning *aurora*, or break of day. Secondly, fine, ſlender luminous beams, well defined, and of denſe light; theſe continue $\frac{1}{4}$, $\frac{1}{2}$, or 1 whole minute, ſometimes at reſt apparently, but oftener with a quick lateral motion. Thirdly, *flaſhes* pointing upward, or in the ſame direction as the beams, which they always ſucceed; theſe are only momentary, and have no lateral motion, but they are generally repeated many times in a minute; they appear much broader, more diffuſe, and of a weaker light than the beams; they grow gradually fainter, till they diſappear. Theſe ſometimes continue for hours, flaſhing at intervals. Fourthly, *arches*, nearly in the form of rainbows; theſe, when complete, go quite acroſs the heavens, from one point of the horizon to the oppoſite point.

When an *aurora* takes place, thoſe appearances ſeem to ſucceed each other in the following order: Firſt, the faint rainbow-like arches; ſecondly, the beams; and, thirdly, the flaſhes; as for the northern horizontal light, it will appear in the ſequel to conſiſt of an abundance of *flaſhes* or *beams* blended together, owing to the ſituation of the obſerver relative to them. Theſe diſtinctions, and the terms appropriated for them, muſt be kept in view, in attending to the following phenomena.

Phenom. 1.—The beams of the *aurora borealis* appear, at all places alike, to be arches of great circles of the ſphere, with the eye in the centre, and theſe arches, if prolonged upwards, would all meet in one point.

Phenom. 2.—The rainbow-like arches all croſs the magnetic meridian at right angles: when two or more appear at once, they are concentric, and tend to the magnetic eaſt and weſt: alſo, the broad arch of the *horizontal light* tends to the magnetic eaſt and weſt, and is biſected by the magnetic meridian; and when the aurora extends over any part of the hemiſphere, whether great or ſmall, the line ſeparating the illuminated part of the hemiſphere from the clear part, is half the circumference of a great circle, croſſing the magnetic meridian at right angles, and terminating in the magnetic eaſt and weſt; moreover, the beams apparently perpendicular to the horizon, are only thoſe on the magnetic meridian.

Phenom. 3.—That point in the heavens to which the beams of the aurora appear to converge at any place, is the ſame as that to which the ſouth pole of the *dipping-needle* points at that place.

Phenom. 4.—The beams appear to riſe above each other in ſucceſſion, ſo that of any two beams, that which has the higher baſe has the higher ſummit alſo, or its ſummit nearer the point of concourſe; the angle ſubtended by the length of each beam is not the ſame, it being greateſt about half way from the horizon to the zenith, and leſs above and below; alſo the beams to the ſouth ſubtend leſs angles than thoſe to the north, having the ſame altitude. The greateſt angle to the north ſeems to be about 25° or 30°; and that to the ſouth 15° or 20°.

Phenom. 5.—Every beam appears broadeſt at, or near, the baſe or bottom, and to grow narrower as it aſcends, in ſuch ſort that the continuation of its bounding lines would meet in the common centre to which the beams tend; yet the ſummit of the beam is not flat, but pointed; the higheſt beams ſeem about 3° broad, and the loweſt 1°.

In order to derive the true ſituation and poſition of the ſeveral objects preſented in theſe phenomena, it was neceſſary to have recourſe to the principles of geometry or perſpective. Mr. Dalton premiſes five propoſitions. The firſt is to ſhew that any line in a plane paſſing through the eye, appears in the heavens to be an arch of a great circle. The other four propoſitions relate to the perſpective appearance of one or more cylinders, ſuppoſed to be arranged upon a horizontal plane at any given elevation above the earth's ſurface, the cylinders being parallel to each other, and making a given angle with the horizontal plane. The propoſitions are illuſtrated by ſuitable diagrams, and demonſtrated in the uſual way. By a compariſon of the data of theſe propoſitions with the above phenomena, the author makes certain inferences reſpecting the aurora borealis, and draws ſuch concluſions as ſeem to be warranted by the eſtabliſhed methods of reaſoning in natural philoſophy. Theſe are,

1. The luminous beams of the aurora borealis are cylindrical, and parallel to each other, at leaſt over a moderate extent of country.

2. The cylindrical beams of the aurora borealis are all *magnetic*, and parallel to the dipping-needle at the places over which they appear.

3. The height of the rainbow-like arches of the aurora, above the earth's ſurface, is about 150 Engliſh miles.

4. The beams of the aurora are ſimilar, and equal in their real dimenſions to one another.

5. The diſtance of the beams of the aurora from the earth's ſurface is equal to the length of the beams nearly. This diſtance is ſubſequently eſtimated at 75 miles.

6. That appearance which we have called the *horizontal light*, and which is always ſituate near the horizon, is nothing but the blended lights of a group of beams, or flaſhes, which makes the appearance of a large luminous zone.

The author next proceeds to develope, at ſome length, an hypotheſis, by which he propoſes to explain theſe wonderful phenomena. It is ingenious, but cannot be conſidered as ſatisfactory. Future inveſtigation may derive from it ſome uſeful hints. The following is a brief ſketch of it.

Mr. Dalton conceives an extremely ſubtile elaſtic fluid of a *ferruginous* nature, or at leaſt ſuch as is capable of being acted upon magnetically, to exiſt in the higher regions of the atmoſphere; perhaps without the verge of the common atmoſphere. That this elaſtic fluid is collected into parallel cylindrical beams, and horizontal rings, over the regions of the earth near the magnetic pole, by virtue of the earth's magnetiſm; and that the beams, &c. are preſerved in their due form and poſition, and diſtinct from each other by their mutual magnetic action. This fluid is ſuppoſed to be an imperfect conductor of electricity. When the electricity of the upper regions of the atmoſphere is diſturbed, it is ſuppoſed the electric fluid runs along theſe beams and rings from one part of the atmoſphere to another, to reſtore the equilibrium. The reaſon why the diffuſe flaſhes ſucceed the more intenſe light of the beams, is becauſe the electricity diſperſes the elementary particles of the beams in ſome degree, which collect again after the electric circulation ceaſes. Hence too, he conceives, is the reaſon of the fluctuations of the magnetical needle below, while the magnetiſm of the upper regions of the atmoſphere is thus affected. The general obſervations on the diſturbance of the needle are ſtated as under.

1. When the aurora appears to riſe only about 5°, 10°, or 15° above the horizon, the diſturbance of the needle is very little, and often inſenſible.

2. When it riſes up to the zenith, and paſſes it there, it never fails to be a conſiderable diſturbance.

3. This diſturbance conſiſts in an irregular oſcillation of the horizontal needle, ſometimes to the eaſtward, and then to the weſtward of the mean daily poſition, in ſuch ſort that the greateſt excurſions on each ſide are nearly equal, and amount to about half a degree each in this place.

4. When the aurora ceaſes, or ſoon after, the needle returns to its former ſtation.

One ſection on the aurora borealis is deſtined to the enquiry, How far the moon has an effect in producing this meteor, or whether the phenomenon is influenced by the aerial tides? It appeared that the average number of auroræ obſerved during the period of ſpring tides, was to the number obſerved during the period of neap tides, as 4 to 3. Alſo, it appeared that ſpring and autumn (ſeaſons in which the tides are uſually higheſt) are moſt favourable for the production of this meteor, as may be ſeen by the following table.

	Number of Auroræ.		Number of Auroræ.
January	18	July	2
February	18	Auguſt	21
March	26	September	23
April	32	October	36
May	21	November	38
June	5	December	9

Some of the moſt ſplendid appearances of the aurora borealis were obſerved in a troubled and rather tempeſtuous ſtate of the atmoſphere; but it did not appear in general that this meteor affords any deciſive prognoſtic of the weather. See Aurora Borealis, Falling *Stones*, &c. Alſo, for other luminous meteors, ſee Rainbow, Halo, Parhelia, Zodiacal Light, &c.

METEORIC Stones. See Falling *Stones*.

METEORISMUS, in *Medicine*, from μετέωρος, *ſublimis*, has been applied by medical writers to that tumid ſtate of the belly, ariſing from flatulence, which diſtends only the upper parts, as the pit of the ſtomach and the hypochondriac regions. See Sauvages Noſol. Method, claſs x. gen. 16, who has made four ſpecies of Meteoriſmus: alſo Caſtelli Lexic. Med. Art. *Meteoros*.

METEOROLOGICAL Journal, is a table recording the daily ſtate of the air, exhibited by the barometer, thermometer, hygrometer, anemometer, and other meteorological inſtruments. We have many journals of this kind kept at the houſe of the Royal Society, and by different obſervers in other places, in the Philoſophical Tranſactions, the Memoirs of the Academy of Sciences, and ſimilar publications.

METEOROLOGY is a ſcience which treats of the weather, or of the various affections and phenomena of the atmoſphere, as *winds*, *clouds*, *rain*, *hail*, *ſnow*, *dew*, *thunder* and *lightning*, and the fiery meteors. The univerſal importance of this ſcience is acknowledged; and it may be ſaid that for 150 years paſt, or ſince the invention of the barometer and the air-pump, almoſt every diſtinguiſhed natural philoſopher has contributed to its advancement, either by the diſcuſſion of hypotheſes or by the obſervation of facts. The difficulty, however, of forming a correct theory of the phenomena of the atmoſphere may eaſily be conceived, when we conſider that it is requiſite for a perſon to have a large collection of facts, and an extenſive acquaintance with ſeveral collateral ſciences; for inſtance, with mechanics, pneumatics, electricity, and chemiſtry.

The principal inſtruments of uſe in meteorology are, the barometer, by which the weight or preſſure of the atmoſphere over any place is known; the thermometer, which aſcertains the temperature of the air; the hydrometer, to denote the moiſture or dryneſs of the air; the pluviameter, or rain-gauge, to meaſure the depth of rain that falls; the evaporation-gauge, to ſhew the depth of water evaporated; the wind-dial, to point out the direction of the wind; the anemometer, to meaſure its force; and the electrometer, to aſcertain the kind and intenſity of electricity in the air. See theſe different inſtruments deſcribed under their appropriate heads.

In order to form a proper notion of the phenomena of the atmoſphere, as exhibited at any one place, it will be neceſſary to obtain a correct notion of the atmoſphere itſelf at large. It appears to be a collection or mixture of various elaſtic fluids in very different proportions, retained on the ſurface of the earth by their gravitation. The principal part of the weight of the atmoſphere ariſes from the permanently elaſtic fluids, azotic gas, and oxygenous gas, the quantities of which are as 4 to 1 nearly: about one part in a thouſand of the atmoſphere is conſtituted of another permanently elaſtic fluid, carbonic acid. The reſt of the atmoſphere conſiſts of aqueous vapour or ſteam, an elaſtic fluid ſubject to partial condenſation by a diminution of temperature. The quantity of this elaſtic fluid is variable at different places and in different ſeaſons; it may perhaps conſtitute $\frac{1}{70}$th of the weight of the whole atmoſphere, conſidered as a general average for the earth; but in ſome places within the torrid zone it may amount to $\frac{1}{30}$th of the weight of the incumbent atmoſphere; and in the polar regions may ſometimes be leſs than $\frac{1}{10,000}$dth part of the atmoſphere. It is this portion of the atmoſphere which more immediately occaſions ſome of the principal phenomena in meteorology, particularly clouds, rain, hail, ſnow, dew, and thunder and lightning: it has conſiderable influence on the temperature of the atmoſphere; but it has little effect in the production of winds, or on the variation of the barometer.

The atmoſphere decreaſes in denſity as we aſcend in a geometrical progreſſion to equal aſcents. As far as experience warrants the concluſion, the ſeveral kinds of gas decreaſe in denſity in the ſame ratio: thus, if at three miles in height, the weight of the atmoſphere is one-half what it is at the earth's ſurface; then will the proportions of the ſeveral elaſtic fluids found in a given volume of air, at that place, be the ſame as what they are in a like volume of air taken at the ſurface of the earth; all the kinds being diminiſhed one-half nearly in weight and denſity. This concluſion is not, perhaps, ſtrictly true for every height, nor for any two heights; but experiments have not been made with ſufficient accuracy to aſcertain the deviation from this law. At ſix miles elevation the barometer would ſtand at $\frac{1}{4}$ the height at the ſurface, or at $7\frac{1}{2}$ inches; at 9 miles of elevation, $3\frac{3}{4}$ inches; at 12 miles, $1\frac{7}{8}$ inch; and at 15 miles, nearly 1 inch. Hence it ſeems that the greateſt part of the atmoſphere is at all times within 15 or 20 miles of the ſurface of the earth; and it is probable that the ordinary phenomena of winds, clouds, rain, &c. are chiefly confined within much narrower limits.

Origin of Winds.—If the atmoſphere ſhould be perfectly calm at any one time all over the ſurface of the earth, it is evident that there muſt be an equilibrium of preſſure, or the weight of air incumbent over every place muſt be the ſame, and the real velocity of the air over any place ariſing from the earth's rotation around its axis, would be the very ſame as that of the place itſelf; namely, at the equator the velocity would be about 1000 miles *per* hour, from W. to E.; and in the lat. of London the velocity would be 620 miles from W. to E.; and at the poles of the earth, the air would have no velocity. If an equilibrium of this kind were once obtained, there appears to be no mechanical reaſon why it ſhould be diſturbed, ariſing out of the circumſtance of the earth's rotation. But if any cauſe ſhould ariſe which diſpoſes the air to move from any part of the earth in a northerly or ſoutherly direction, it is alſo evident that the rotation of the earth would conſpire with this cauſe to modify the direction, and to accelerate the velocity of the current of air ſo produced. For inſtance, ſuppoſe a body of air in the lat. of London was to receive an impulſe or ſeries of impulſes, ſuch as to compel it to move 10° ſouthward in a day, with an uniform velocity; this current of air gradually paſſing through other air of greater velocity eaſtward, will in part be carried along with the current, and when it arrives at the 10th parallel it will find air diſpoſed to move from W. to E. with a velocity of 750 miles *per* hour, being the velocity of the place; whereas its own velocity in that direction was only 620 miles. Now if the moving current of air have not acquired the additional velocity of 130 miles *per* hour from W. to E., it muſt appear at the place to have a motion from E. to W. with a velocity equal to the difference or deficiency; ſuppoſe it has only acquired 105 miles additional velocity eaſtward, then it will appear to move at the rate of 25 miles *per* hour weſtward; and as it moves alſo 25 miles ſouthward each hour, it is manifeſt its direction will be truly that of a N.E. wind, and its velocity 35 miles *per* hour. If the air is impelled northward, inſtead of ſouthward, then *vice verſâ*, a S.W. wind is produced. It appears, then, that as ſoon as any cauſe operates to impel a portion of the atmoſphere either north or ſouth, that inſtant the rotation of the earth on its axis begins to manifeſt an effect, which is to accelerate the apparent velocity of the current, and to divert its direction. We are then directed to look for ſome natural cauſe or ſtimulus which may, either occaſionally or conſtantly, operate in impelling the atmoſphere in a meridional direction. This cauſe is found in the unequal temperature of the atmoſphere in the different zones of the earth. The torrid zone is always the warmeſt region of the earth. The temperate zones are colder; but alternately approximate to the temperature of the torrid zone. The frigid zones are colder ſtill, but they alſo alternately make ſome approximation to the temperature of the torrid zone. Now it is well known that air is expanded by heat, and hence becomes ſpecifically lighter; the air over the torrid zone being then ſpecifically lighter than the air in the temperate zones, it will have a tendency to aſcend, whilſt the air in the two temperate zones will preſs forward to ſupply the vacancy, and the air in the frigid zones will follow after upon the ſame principle. Hence it appears that there muſt always be a draught of air from the polar towards the equatorial regions, greater

greater or lefs according to the exifting difference of temperature. As, however, an accumulation of air in the torrid zone would thus enfue, and a deficiency in the other zones, means muft be found to return the excefs of air over the torrid zone into the northern and fouthern regions. This is effected, without doubt, by the upper regions of the atmofphere in the torrid zone meeting with a lefs lateral preffure than is adequate to fupport them. The air rifes up, and overflows in fome degree, fo that currents northward and fouthward are eftablifhed, in oppofite directions to the two former currents, and fuperior to them. The two under currents, as has been fhewn, will be N.E. and S.E. winds; the two upper currents, by a like method of reafoning, will be S.W. and N.W. winds. The two under currents, or the N.E. and S.E., meeting each other in the torrid zone, their velocities N. and S. are deftroyed by their oppofition, but their velocity from E. to W. continues, and occafions the regular or trade-winds. But it is not our defign in this place to do more than point out the great active principles, which are conftantly at work to produce a motion and circulation of the atmofphere; a more particular defcription and detail will be given under the article WINDS. The principle, however, cannot but be allowed by thofe who duly confider the effect of the earth's rotation, and the currents of air we ordinarily obferve in any room containing a fire.

Origin and Nature of Clouds.—Clouds are conftituted of an infinite number of very minute drops of water; they are formed by the condenfation of fteam or vapour by cold. In order to underftand their origin, we muft take a view of the atmofphere of fteam already mentioned, and confider its rife and properties. Steam, as every one knows, is an elaftic fluid arifing from the union of water and heat; and it is again condenfible into water by cold, fo as to lofe its elafticity. Steam is formed almoft inftantaneoufly from water inclofed in a vacuum; the maximum effect is at once produced, and there is an end of the evaporation, unlefs the temperature is increafed. The fame effect is produced when the water is inclofed in the fame volume of perfectly dried common air, or any other kind of air perfectly dried, not acting chemically on water. The fame quantity of water, in this cafe as in the former, is converted into vapour, and the fame elaftic force of fteam is produced for the maximum effect; but there is this difference in the two cafes, the latter requires a fenfible *time*, in order that the maximum effect may be produced. This demonftrates that the prefence of air retards evaporation, and that in all probability is, by reafon of its preffure on the furface of the water. From all thefe obfervations it might be expected that evaporation would go on, and the quantity of fteam in the air increafe till the maximum effect was produced over all the earth, and then there would be a total ceffation. But we find that evaporation is unceafingly going on in almoft every place, and even at the very place where rain is defcending. This curious fact would appear at firft view to be of difficult explanation; but the difficulty is not infurmountable, as will prefently be fhewn.

It appears that the quantity of fteam that can be contained in a veffel, either with or without air, increafes nearly in geometrical progreffion to equal intervals of temperature. Mr. Dalton contends that the increafe is *accurately* in geometrical progreffion, and that the intervals of temperature are not duly meafured by the common thermometer; however this may be, there can be no doubt that the former increafes more rapidly than the latter. It has been found, that if the maximum of fteam in air of 32° be denoted by 2, that of air of 52° will be denoted by 4, and that of air of 72° by 8. (See Dalton's Chemiftry, p. 14.) Hence it is obvious, that if equal portions of air of 32° and 72°, both faturated with vapour, were mixed together, the mean temperature would be 52°, and the quantity of vapour prefent in the mixture would be 10; whereas, the greateft quantity of vapour that the air of that temperature could contain, is only 8, according to the above ftatement; whence two parts muft be condenfed, and would firft appear in the fhape of a cloud, and be ultimately depofited. Here, then, we perceive the origin of clouds and rain. It has been fhewn that an unceafing circulation of air between the equatorial and polar regions takes place; and as both currents of air muft be fuppofed to be near the point of faturation with vapour, there muft frequently be a cloud formed by their mixture. The current from the equator is warm and full of vapour, compared with the air of like altitude in the northern and fouthern regions; and *vice versâ* with regard to the air from the north and fouth towards the equator. This laft air is cold, but nearly faturated with vapour for its temperature; and hence will precipitate vapour from warm air. Were the currents of air to and from the equator quite faturated with vapour at their departure, there muft be perpetual cloudinefs to accompany their progrefs; but the circulation of air is fo quick, and the faturation with vapour is flowly effected by reafon of the preffure of the atmofphere, that it rarely happens for the currents to be faturated at their commencement. It is eafy to fee, then, that this circumftance, with others equally obvious, may modify the effects fo far, as that the atmofphere may be either clear or cloudy over any place whilft the general currents are making their ordinary progrefs. It is owing to the fame circumftance (the flownefs with which fteam circulates itfelf through the air) that two currents of air may meet in the higher regions of the atmofphere, and a precipitation of vapour may enfue, when the inferior ftrata of air are not faturated with vapour. This, indeed, is generally the cafe in fhowery weather, but never in long continued rain. The more particular details of this theory of rain will be better deferred till the article *Rain* is compofed. See RAIN, alfo CLOUDS, EVAPORATION, &c.

If any doubt fhould remain as to the correctnefs of the above views in regard to the formation of clouds and rain, it may be completely removed, if we will take the trouble to examine the phenomena of a drying ftove. We may there fee the procefs above defcribed completely copied in miniature. The moment we open the door to enter the ftove, the cold air rufhes in, and a prodigious cloud is inftantly formed, fo as to render furrounding objects invifible: foon after the door is fhut, the cloud difappears, and the internal air refumes its ufual tranfparency. Here, then, is an inftance of a current of cold air rufhing into warm, both of them being below the point of faturation with vapour, and yet a great precipitation takes place. Again, if we notice the air which has afcended the air-flues of the ftove and is mixing with the atmofphere, we find a copious ftream or cloud of condenfed vapour fpreading itfelf all around. This is formed by the current of warm air rufhing into the cold atmofphere, though both of them are ufually below the point of faturation with vapour.

Height of the Clouds.—We fhall fubjoin the refults of a feries of obfervations on the height of the clouds: thefe are the more valuable, as very few meteorologifts have an opportunity of making fimilar obfervations. They were made by Mr. Crofthwaite, of Kefwick, in Cumberland. In mountainous countries the clouds frequently furround the hills, like a girdle, and exhibit a fmooth horizontal furface; if the

the height of the hill at the point of interfection be known by previous obfervation, then the mountain may be made into a fcale to meafure the altitude of the clouds. The mountain Skiddaw was fixed upon for that purpofe, and Mr Crofthwaite determined its height above Derwent lake to be 1050 yards. This altitude is probably too great, but the error will have no material effect in the prefent confideration.

"The refult of five years' obfervations is contained in the following table. In order to determine what effect the feafons of the year have upon the clouds in this refpect, we have kept the obfervations in the feveral months diftinct. It is to be noted, that the column containing the number of obfervations when the clouds were above Skiddaw, includes thofe obfervations when there were no clouds vifible; but Mr. Crofthwaite has noted this laft circumftance alfo in the journal, and it appears that about one obfervation in thirty, of thofe in that column, fhould be deducted on that account.

	Clouds from 0 to 100 Yards high.	From 100 to 200 Yards high.	From 200 to 300 Yards high.	From 300 to 400 Yards high.	From 400 to 500 Yards high.	From 500 to 600 Yards high.	From 600 to 700 Yards high.	From 700 to 800 Yards high.	From 800 to 900 Yards high.	From 900 to 1000 Yards high.	From 1000 to 1050 Yards high.	Above 1050 Yards high.	Number of Obfervations.

"It may be proper to obferve, that the fuppofition of the clouds rifing or falling with the barometer, or as the denfity of the air increafes or diminifhes, is not at all countenanced by thefe obfervations. Alfo, that in very heavy and continued rains the clouds are moftly below the fummit of the mountain; but it frequently rains when they are entirely above it." Dalton's Meteorology, p. 40.

By comparing the parts of the above table, it is manifeft that clouds are at an average higher in fummer than in winter; and by analogy, we may conclude that clouds are higher in the torrid zone than in the temperate zones, and higher in thefe laft than in the frigid zones. From the above obfervations it would feem, that the large, denfe, opaque clouds feldom are found more than one mile elevated in this country; but the thicknefs of the cloudy ftratum is unknown, and may perhaps be feveral hundred yards. Different ftrata of clouds are fometimes obferved one above another, in fummer efpecially. Small white ftreaks of cloud are fometimes feen at the elevation of three, four, five miles, or more. In thefe high regions, any condenfation that can take place is probably infufficient to produce a cloud of great denfity or opacity.

Sufpenfion of Clouds.—It appears to many people wonderful how large and denfe clouds, confifting of drops of water, fhould be fo long fufpended in the air, as fome of them feem to be, without materially defcending; efpecially as water is 800 times the weight of air. This is to be explained on two principles: the one is, that bodies in a ftate of extreme divifion are much more refifted in their motion through the air, or any other fluid, than when in large portions. Gravity, or the force of defcent, remains the fame whether the body is divided or not; but the furface increafes with the divifion of the body, and the refiftance increafes with the furface. Hence it is that the extremely fmall drops, conftituting clouds, fall very flowly, till they begin to coalefce or increafe in fize. The other principle is, that fmall drops falling into a ftratum of air not faturated with vapour, are frequently refolved again into fteam; thus, that part of the cloud which actually defcends difappears; and it not unfrequently happens that the whole cloud vanifhes in this way, being again converted into vapour, and blended with the general mafs of the atmofphere.

Rain, Snow, Hail, and Dew.—Whenever two currents of air of different temperatures meet and intermix, each of which is previoufly near the point of faturation with vapour, or whenever a body of atmofpheric air is fuddenly cooled (as by the rarefaction occafioned by the ftroke of an air-pump, or by opening the cock of a condenfing engine), a cloud is formed, and a precipitation often enfues. The precipitation is in the form of rain if the temperature be above 32° Fahr., but in the form of fnow if the temperature be below the faid degree. Rain or fnow is ordinarily obferved in all latitudes; but in the torrid zone the latter is confined to the fummits of the higheft mountains. Hail is an extraordinary form in which the vapour is precipitated; it feems to arife from an inverfion of the ftrata of the atmofphere, by which a cold ftratum is placed beneath a warmer one, contrary to the general difpofition of the atmofphere. Rain is formed in the upper ftratum, and this falling through the under ftratum is cooled and frozen, receiving at the fame time a confiderable acceffion from the condenfation on the furfaces of the frozen drops. Hail-fhowers occur in all

feafons

feaſons of the year, but more rarely in the ſummer months; they, however, ſometimes accompany thunder in thoſe months, and are peculiarly deſtructive and formidable. Hail ſeems to be confined principally to the temperate zones: it is probable that in this quarter of the globe hail is ſeldom obſerved, except between the parallels of 40° and 60° of latitude. It is more frequent in mountainous places than on plains; in the former hail-ſhowers uſually occur on five or ſix days of the year at an average.

Dew is formed when, inſtead of cold air mixing with warm, a cold ſolid or liquid body is preſented to (comparatively) warm air. There exiſts a determinable temperature at all times, which is juſt capable of ſupporting the vapour of the atmoſphere in an elaſtic ſtate. (See HYGROMETRY, *on the Dew-point.*) If the temperature of the cold body be below this, then the vapour of the atmoſphere is gradually condenſed into water on its ſurface: this is a well-known phenomenon, and preſented on various occaſions. The dew on the graſs and the hoar on walls after the breaking of a froſt, are two of the more ſtriking appearances of this kind.

Temperature of the Atmoſphere.—This important ſubject has already been treated upon at large under the heads, ATMOSPHERE, *Temperature of the;* and HEAT, in *Geography*, to which we muſt therefore refer. There is, however, one remarkable character of the atmoſphere, namely, that of the uniform decreaſe of temperature in aſcending, which has never been ſatisfactorily explained. An ingenious eſſay on this ſubject has lately been publiſhed, from which we ſhall here give an extract.

"It is a remarkable fact, and has never, I believe, been ſatisfactorily accounted for, that the atmoſphere in all places and ſeaſons is found to decreaſe in temperature in proportion as we aſcend, and nearly in an arithmetical progreſſion. Sometimes the fact may have been otherwiſe, namely, that the air was colder at the ſurface of the earth than above, particularly at the breaking of a froſt I have obſerved it ſo; but this is evidently the effect of great and extraordinary commotion in the atmoſphere, and is at moſt of a very ſhort duration. What then is the occaſion of this diminution of temperature in aſcending? Before this queſtion can be ſolved, it may be proper to conſider the defects of the common ſolution. Air, it is ſaid, is not heated by the direct rays of the ſun, which paſs through it as a tranſparent medium, without producing any calorific effect, till they arrive at the ſurface of the earth. The earth being heated, communicates a portion to the contiguous atmoſphere, whilſt the ſuperior ſtrata, in proportion as they are more remote, receive leſs heat, forming a gradation of temperature, ſimilar to what takes place along a bar of iron when one of its ends is heated.

"The firſt part of the above ſolution is probably correct: air, it ſhould ſeem, is ſingular in regard to heat; it neither receives nor diſcharges it in a radiant ſtate; if ſo, the propagation of heat through air muſt be effected by its conducting power, the ſame as in water. Now we know that heat applied to the under ſurface of a column of water is propagated upwards with great celerity, by the actual aſcent of the heated particles: it is equally certain, too, that heated air aſcends. From theſe obſervations it ſhould follow, that the cauſes aſſigned above for the gradual change of temperature in a perpendicular column of the atmoſphere, would apply directly to a ſtate of temperature the very reverſe of the fact; namely, to one in which the higher the aſcent, or the more remote from the earth, the higher ſhould be the temperature.

"Whether this reaſoning be correct or not, it muſt, I think, be univerſally allowed, that the fact has not hitherto received a ſatisfactory explanation. I conceive it to be one involving a new principle of heat; by which I mean a principle that no other phenomenon of nature preſents us with, and which is not at preſent recogniſed as ſuch. I ſhall endeavour in what follows to make out this poſition.

"The principle is this:—*The natural equilibrium of heat in an atmoſphere, is when each atom of air in the ſame perpendicular column is poſſeſſed of the ſame quantity of heat;* and, conſequently, *the natural equilibrium of heat in an atmoſphere is when the temperature gradually diminiſhes in aſcending.*

"That this is a juſt conſequence cannot be denied, when we conſider that air increaſes in its capacity for heat by rarefaction; when the quantity of heat is given or limited, therefore, the temperature muſt be regulated by the denſity.

"It is an eſtabliſhed principle, that any body on the ſurface of the earth unequally heated is obſerved to tend conſtantly towards an equality of temperature: the new principle announced above, ſeems to ſuggeſt an exception to this law. But if it be examined, it can ſcarcely appear in that light. *Equality of heat and equality of temperature*, when applied to the ſame body in the ſame ſtate, are found ſo uniformly to be aſſociated together, that we ſcarcely think of making any diſtinction between the two expreſſions. No one would object to the commonly obſerved law being expreſſed in theſe terms: *When any body is unequally heated, the equilibrium is found to be reſtored when each particle of the body becomes in poſſeſſion of the ſame quantity of heat.* Now the law thus expreſſed is what I apprehend to be the true general law, which applies to the atmoſphere as well as to other bodies. It is an *equality of heat*, and not an *equality of temperature*, that nature tends to reſtore.

"The atmoſphere, indeed, preſents a ſtriking peculiarity to us in regard to heat: we ſee in a perpendicular column of air, a body without any change of form, ſlowly and gradually changing its capacity for heat from a leſs to a greater; but all other bodies retain a uniform capacity throughout their ſubſtance.

"If it be aſked why an equilibrium of heat ſhould turn upon the equality in *quantity* rather than in *temperature?* I anſwer, that I do not know; but I reſt the proof of it upon the fact of the inequality of temperature obſerved in aſcending into the atmoſphere. If the natural tendency of the atmoſphere was to an equality of temperature, there does not appear to me any reaſon why the ſuperior regions of the air ſhould not be at leaſt as warm as the inferior.

"The arguments already advanced on behalf of the principle we are endeavouring to eſtabliſh, are powerfully corroborated by the following facts:—By the obſervations of Bouguer, Sauſſure, and Gay Luſſac, we find that the temperature of the air at an elevation where its weight is $\frac{1}{2}$, that at the ſurface is about 50° Fahrenheit leſs than that at the ſurface; and from my experiments (Manch. Memoirs, vol. v. p. 525.) it appears that air being ſuddenly rarified from 2 to 1, produces 50° of cold. Whence we may infer, that a meaſure of air at the earth's ſurface being taken up to the height above-mentioned, preſerving its original temperature, and ſuffered to expand, would become two meaſures, and be reduced to the ſame temperature as the ſurrounding air; or *vice verſâ*, if two meaſures of air at the propoſed height were condenſed into one meaſure, their temperature would be raiſed 50°, and they would become the ſame in denſity and temperature, as the like volume of air at the earth's ſurface. In like manner we may infer, that if a column of air from the earth's ſurface to the ſummit of the atmoſphere were condenſed, and brought into a horizontal poſition on the earth's ſurface, it would become

of

of the fame denfity and temperature as the air around it, without receiving or parting with any heat whatever.

" Another important argument in favour of the theory here propofed, may be derived from the contemplation of an atmofphere of vapour. Suppofe the prefent aerial atmofphere were to be annihilated, and one of fteam or aqueous vapour were fubftituted in the place; and fuppofe, further, that the temperature of this atmofphere at the earth's furface were every where 212°, and its weight equal to thirty inches of mercury. Now at the elevation of about fix miles the weight would be fifteen inches or one-half of that below, at twelves miles it would be 7.5 inches, or one quarter that at the furface, &c. and the temperature would probably diminifh 25° degrees at each of thefe intervals. It could not diminifh more; for we have feen (p. 14.) that a diminution of temperature of 25° reduces the force of vapour one-half; if, therefore, a greater reduction of temperature were to take place, the weight of the incumbent atmofphere would condenfe a portion of the vapour into water, and the general equilibrium would thus be difturbed perpetually from condenfations in the upper regions. But if we fuppofe, on the other hand, that the diminution of temperature in each of thefe intervals is lefs than 25°, then the upper regions would admit of more vapour without condenfation; but it muft take place at the furface, becaufe vapour at 212° cannot fuftain more than the weight of thirty inches of mercury." Dalton's New Syftem of Chemical Philofophy, p. 123.

Thunder and Lightning.—Of all the atmofpherical phenomena there are none more awfully fublime than thofe of thunder and lightning. Refpecting the nature and caufe of thefe it would be ufelefs to cite the opinions of ancient philofophers, as all our real knowledge on thefe fubjects is derived from modern difcoveries, and particularly thofe in electricity. Dr. Franklin afcertained the identity of lightning and electricity; fince then the attention of philofophers has been directed to the inquiries, how the electric fluid or energy circulates from the earth to the air and back again to the earth; by what means it is raifed into the atmofphere, how it becomes redundant, and how it is returned to the earth again. The aqueous vapour, or fteam of the atmofphere, appears to be the vehicle. The dry and permanent elaftic fluids have probably no more to do than as non-conductors of electricity to obftruct its paffage through the atmofphere. When water is evaporated it takes along with it a greater quantity of electricity, as well as heat, than it had before; that is, the capacity of vapour for electricity is greater than that of water. This fact has been obferved by moft of thofe who have, of late years, carefully attended to electrical phenomena. (See *Electricity of the* ATMOSPHERE.) Of courfe when the fteam is condenfed into water, there muft be a redundance of electricity as well as of heat; and if the air be a non-conductor (as it undoubtedly is when dry), the drops of water, or the cloud formed, muft be electrified pofitively. This is afcertained to be the fact; indeed it may be feen in the article above referred to, that the electricity of the atmofphere is almoft univerfally pofitive. If, during a thunder-ftorm, and on fome few other occafions, the atmofphere exhibit figns of negative electricity, it can fcarcely be doubted that this is occafioned by the action of fome fuperior cloud, which being pofitively electrified, makes the other, or the circumambient air, negative by induction, agreeably to the well-known law of electricity. The reafon why the atmofphere cannot be negatively electrified is, that in the ordinary courfe of nature *no evaporation of water infulated by the atmofphere can ever take place;* the evaporation being always originally from the earth's furface. We have obferved, indeed, that clouds are fometimes re-diffolved in the air; but then thefe clouds being infulated muft have their excefs of electricity about them, and confequently will not rob the atmofphere at large of any electricity that naturally belongs to it.

Conformably to thefe obfervations then, we may lay it down as an eftablifhed maxim, that *the electricity of every cloud at its formation is pofitive.* It will remain then to be explained how the phenomena of thunder and lightning are to be accounted for on this pofition. One moft obvious queftion occurs; if the electricity of one cloud find it expedient to force its way to the earth by a violent difcharge, why is it not univerfally the cafe, and why are not thunder and lightning as frequent as clouds and rain?

Before this queftion can be fatisfactorily anfwered, we muft make ourfelves acquainted with the circumftances that ufually accompany thunder and lightning. It will be generally allowed, that the frequency of thunder and lightning, in this part of the world at leaft, is in proportion to the quantity of aqueous vapour in the atmofphere, or, which nearly amounts to the fame thing, to the temperature of the air. The following extract from Dalton's Meteorology, being the refult of five years' obfervations, will fupport this affertion. See pages 29 and 46.

	Jan.	Feb.	March.	April.	May.	June.	July.	Aug.	Sept.	Oct.	Nov.	Dec.
Mean temperature each month	37°	39°	39°	45°	51°	56°	57°	58°	53°	46°	41°	35°
Number of days when thunder was heard	1	0	0	3	7	5	12	7	4	2	0	1

In fact, thunder is very rare in winter, perhaps never known in froft, more frequent in fpring and autumn; but it is in the months of May, June, July, Auguft, and September, which are the warmeft months in the year, that we ufually expect, and have to record thunder-ftorms of any confequence or duration. Of thefe months, July, which is the middle of the feries, is generally the warmeft, and from the above ftatement appears pre-eminent for thunder-ftorms. It is further remarkable, that when thunder is obferved in winter, *it is always during a low barometer, and an unufually warm vapoury ftate of the atmofphere;* alfo in fummer, whenever the dew-point temperature arrives at a maximum for the feafon (that is, from 55° to 62°, or upwards), it is reduced for the moft part by a thunder-ftorm and confiderable rain. With regard to other climates, it is known that thunder is frequent and violent in low latitudes, and in all places where the extremes of heat and moifture are found; but we do not often hear of its effects in high latitudes where neither heat nor moifture can be long prevalent. Whenever vapour is precipitated from the atmofphere by the caufes we have already affigned, the quantity will be greater in proportion as the abfolute quantity of aqueous vapour in the atmofphere is greater: this arifes from the increafe of vapour being in a geometrical progreffion to that of temperature in arithmetical progreffion. Rain, with the dew-point at 60°, will be twice as heavy, all other circumftances the fame, as rain with the dew-point at 40°; becaufe there is twice as much fteam in the air in the former cafe. It has already been obferved, that the clouds are higher or more elevated above the furface of the earth in fummer than in winter. From combining thefe obfervations we may, perhaps, obtain a fatisfactory reafon for thunder not accompanying every cloud and fhower of rain. In winter the clouds are low, lefs denfe, and confequently lefs electric,

electric, than in ſummer; their electricity ſilently and ſlowly ſteals away to the earth's ſurface. In ſummer the intenſity of the electricity is double, in conſequence of its quantity being as the vapour condenſed, and it is more removed from the earth, or inſulated by its ſuperior altitude; hence its energy may be ſo far increaſed as to overcome the reſiſtance of the air. Thus, if an imperfectly rounded ball be preſented at a proper diſtance from the conductor of an electrical machine, it will ſlowly and ſilently draw off the electricity; but if the intenſity of the electricity be increaſed ſufficiently, nearly the whole will come away in an inſtant in the ſhape of a denſe ſpark, with a ſnapping noiſe.

There is another circumſtance which probably has conſiderable influence in giving a highly vapourized air its character for favouring thunder. It admits of ſeveral ſtrata of clouds arranged one beneath another, which will operate like the ſeries of plates in the Voltaic pile in increaſing the intenſity of their electric charge. This diſpoſition cannot well occur in winter, as the higher air is too deficient in vapour to ſpare an adequate quantity for the purpoſe.

One very remarkable character of thunder has not been duly noticed by philoſophers; that is, the long continuance of each ſingle peal. It may, perhaps, be ſafely aſſerted, that the duration of a peal of thunder is at an average about twenty ſeconds; it is certainly longer in many inſtances. Now, as the flaſh of lightning is inſtantaneous, we have no rational method of explaining the continuance of the ſound, but by ſuppoſing the diſcharge to extend for a great many miles; if the ſound continue half a minute, the diſcharge cannot be leſs than through the ſpace of ſeven miles, but may be twice as much, or more. How, then, is this great length of the diſcharge to be explained? In order to meet this queſtion, we may remark, that clear air is a bad conductor of electricity, but that clouded air poſſeſſes a kind of middle quality, of being neither a good conductor, nor a good non-conductor. We may ſuppoſe that the ſame electric energy which forces a way through 100 yards of clear air, may be capable of forcing a way through 10,000 yards of denſely-clouded air. Hence we may account for the long continuance of thunder, by ſuppoſing that the electricity of a ſuperior cloudy ſtratum ſtrikes an inferior ſtratum at the neareſt point, and runs along it for a number of miles. The ſound arrives at the ear from the neareſt point of the courſe firſt, and afterwards ſucceſſively from the more remote points, and thus occaſions the continuance of the ſound. This view of the ſubject is corroborated by the obſervation, that whenever a clap of thunder is noticed to be remarkably near, or to ſucceed the flaſh immediately, by one inhabitant of any large town, it is noticed in like manner by moſt of the other inhabitants, though ſituate ſome miles diſtant from each other.

Thunder may be heard to the diſtance of ten or fifteen miles, but ſeldom further; this is aſcertained from a calculation of the velocity of ſound during the interval between the flaſh and the report in a dark night. It is uncertain to what diſtance lightning may be ſeen; we ſometimes ſee it in the night when no clouds are viſible; in this caſe it muſt be at a great diſtance, perhaps one or two hundred miles, or more. In ſuch caſes the flaſhes are obſerved to be much more frequent than when the thunder is near; this ſeems to indicate that in the latter inſtance we do not perceive all the lightning of the ſtorm.

Cauſes of the Variation of the Barometer.—One of the moſt difficult problems in meteorology is to aſſign the cauſes for the daily changes in the weight of the atmoſphere. Various opinions have been held with regard to theſe cauſes, many of which are too futile to merit animadverſion. This ſubject has already received an ample diſcuſſion under the head Barometer, *Cauſe of the Phenomena of*, ſo that we ſhall be brief on the preſent occaſion. It may be proper, in the firſt place, to ſtate the leading facts: namely, that the variation of the barometer is leaſt in the torrid zone, and is greater, as we proceed thence northward or ſouthward; that in the temperate and frigid zones, the variation is always greater in winter than in ſummer. We ſhall take for granted that the whole atmoſphere of the earth continues the ſame in quantity, and that the variations of the barometer ariſe from unequal diſtribution of the atmoſphere, and not from any generation or deſtruction of elaſtic fluids. We ſhall alſo take for granted that any changes in the aqueous vapour of the atmoſphere are inſufficient to explain the phenomena, becauſe if the whole quantity of aqueous vapour in the atmoſphere were withdrawn from any place on any occaſion, it would not depreſs the barometer one quarter of what is frequently obſerved in high northern latitudes in winter.

Mr. Kirwan's idea that the atmoſphere is higher over the equator than over the poles, owing to the difference of temperature in thoſe two regions, and that the currents occaſioned thereby are inſtrumental in producing the changes of the barometer, is certainly entitled to our conſideration. On this principle Mr. Dalton has conſtructed a table to ſhew the relative heights of the barometer at given elevations over the equator, the north of England, and the north pole. (Meteorology, page 83.) "The mean heat at the earth's ſurface under the equator is ſuppoſed 84°; the mean heat in theſe parts for the hotteſt month of ſummer at 60°, and for the coldeſt month of winter at 35°. The mean annual temperature at the north pole being ſuppoſed 31°, the mean temperature for the coldeſt month of winter at that place may perhaps be ſtated at 2°."

Elevation of the Barometer above the Level of the Sea in English Miles.	Height of the mercurial Column of the Barometer in Inches.			
	Above the Equator.	Above the North of England.		Above the North Pole.
		In Summer.	In Winter.	In Winter.
0	30.00	30.00	30.00	30.00
2	20.55	20.10	19.58	18.81
4	13.61	12.96	12.24	11.19
6	8.66	7.98	7.26	6.24
8	5.25	4.65	4.03	3.19
10	3.00	2.52	2.05	1.45
12	1.58	1.24	.93	.56

From this table it ſhould ſeem, that the weight of air in a vertical column of ſix miles over the equator is nearly equal to that of a column of five miles over the pole in winter: that is, the heights of the atmoſphere at the equator and pole are as 6 to 5 nearly. But the relation between the equator and the north of England in this reſpect, in ſummer is as 16 to 15, and in winter as 8 to 7 nearly. Now when the variations in the altitudes are greateſt (in winter), the energy or velocity of the great northern and ſouthern currents of air is greateſt, as has been ſhewn above on winds, and therefore the irregularities occaſioned by the interference, &c. of theſe currents muſt then be alſo at their greateſt. Theſe irregularities are ſhewn by the barometer. If we were to ſuppoſe that, from ſome extraordinary incidents, the atmoſphere over the north of England

land in winter were raised to the same elevation as that over the equator, all other circumstances being the same, the barometer must rise nearly four inches; and it would sink four inches if the atmosphere were depressed as much below the mean. But this supposition is much too extravagant to be admitted, and indeed the facts do not call for any thing near it. The barometer rarely rises or falls more than one and a half inch from the mean in this country; and consequently a slight variation of the mean altitude of the atmosphere is all that is required, and such may well be admitted.

Besides this variation of the mean altitude of the atmosphere, Mr. Dalton thinks there is another cause that acts in combination with it to produce the extraordinary falls of the barometer in winter, (which are observed to go below the mean more than the rises go above it.) He supposes, that during a violent S.W. wind on the occasion of a thaw (at which time the minimum usually takes place), a temporary change in the law of temperature in ascending exists. That the temperature in ascending is then more nearly uniform than at other times; by which means the elasticity in the lateral directions will be equal to any force that may be opposed, whilst the weight of a vertical column will be less than otherwise. See Meteorology, page 109.

For further information on meteorology, see ANEMOMETER, ATMOSPHERE, BAROMETER, CLOUD, DEW, EVAPORATION, FOG, HAIL, HYGROMETRY, LIGHTNING, METEOR, RAIN, SNOW, THERMOMETER, THUNDER, WIND, &c.

METEOROMANCY, a species of divination by meteors, principally by lightning and thunder: this method of divination passed from the Tuscans to the Romans, with whom, as Seneca informs us, it was held in high esteem.

METEOROS, μετεωρος, from μετα, and αιρω, *to elevate*, in *Medicine*, elevated, suspended, sublime, erect, tumid. Thus μετεωρα αλγηματα, are expounded by Galen, Com. ad. Aph. 7. lib. vi. sublime pains: those which are above the peritonæum, or affect the superficial and external parts of the body. These pains are opposed to such as are deeply seated, and called τα μη μετεωρα, not sublime, but deep, and seated within the peritonæum.

METEOROSCOPE, from μετεωρος, *high*, and σκοπος, of σκεπτομαι, *I view, observe*, a name which the ancient mathematicians gave to such instruments as they used for observing and determining the distances, magnitudes, and places of the heavenly bodies; many of which they regarded as meteors.

The name, however, may much more properly be applied to meteorological instruments.

METEPEC, in *Geography*, a town in the province of Mexico.

METERISCH, a town of Moravia, in the circle of Iglau; 17 miles E. of Iglau.

METESSIB, an officer of the eastern nation, who has the care and oversight of all the public weights and measures, and sees that things are made justly according to them.

METEYARD, in *Rural Economy*, a term applied to a staff or beam of a certain length for taking measures.

METEZAU, CLEMENT, in *Biography*, a celebrated French architect, who flourished in the former part of the 17th century, was a native of Dreux, but settled at Paris, became architect to Lewis XIII., and acquired much fame by carrying into execution, with Tiriot, a Parisian mason, the plan suggested by cardinal Richelieu for reducing Rochelle, by means of an immense dyke, in imitation of what Cæsar had done at Durazzo, and Alexander the Great at Tyre. This scheme was to run a solid wall across a gulf upwards of 740 fathoms, or more than three quarters of a mile broad, into which the sea rolled with great force, and when the wind was high, with an impetuosity which seemed to set at defiance the art of man. Those who had undertaken the business were not to be turned aside by any obstacles: they began, by throwing in huge rocks, to lay a kind of foundation; upon these were placed vast stones, cemented by the mud thrown up by the sea. These were supported by immense beams, driven into the bottom with incredible labour. It was raised so high, that the soldiers were not incommoded by the water, even at spring tides. The platform was nearly 30 feet wide, and 90 feet at the foundation. At each extremity there was a strong fort, in the middle there was an open passage of 150 paces, several vessels being sunk immediately before it, together with high stakes in a double row, and before these 35 vessels linked together, so as to form a kind of floating pallisade. This amazing dyke was completed in somewhat less than six months, and proved the principal means of occasioning the surrender of the city. So honourable were the exertions of M. Metezau in this business, that his portrait was circulated widely through France, to which were attached the following lines,

> "Dicitur Archimedes Terram potuisse movere:
> Æquora qui potuit sistere, non minor est."

METH, METI, or *Mott*, in *Geography*, a small island near the coast of Africa, at the entrance of Babelmandeb, with a town upon it. N. lat. 11° 15′. E. long. 48° 45′.

METHANA, a town of the Morea, near the coast of the gulf of Engia; 56 miles E.S.E. of Napoli di Romania.

METHEGLIN, a drink prepared of honey; one of the most pleasant and general drinks the northern parts of Europe afford; and much used among the ancient inhabitants.

The word is Welsh, *meddyglin*, in which it signifies the same. There are divers ways of making it; one of the best of which follows: put as much new honey, naturally running from the comb, into spring water, as that, when the honey is thoroughly dissolved, an egg will not sink to the bottom, but be just suspended in it; boil this liquor for an hour, or more, till such time as the egg swim above the liquor about the breadth of a groat; when very cool, next morning, it may be barrelled up; adding to each fifteen gallons an ounce of ginger, as much of mace and cloves, and half as much cinnamon, all grossly pounded: a spoonful of yeast may be also added at the bung-hole, to promote the fermentation. When it has done working, it may be closely stopped up; and, after it has stood a month, it should be drawn off into bottles. See MEAD.

METHO, in *Geography*, a small independent country of Africa, S.E. of Fittré.—Also, a town of the Morea; 34 miles E.S.E. of Napoli di Romania.

METHOD, METHODUS, from μεθοδος, in *Logic* and *Rhetoric*, the art or rule of disposing things in such a manner, as that they may be easily comprehended; either in order to discover the truth, of which we ourselves are ignorant; or to shew or demonstrate it to others when known, or to fix it in the memory. See DISPOSITION.

Gassendus distributes method, with regard to its object, into three kinds, or branches, *viz.* inventionis, *the method of invention*, or discovering a truth unknown.

Methodus judicii, the method of judging or determining of a truth, or position, proposed.

And

And *methodus demonſtrationis,* or method of demonſtration; that is, of exhibiting it to another.

Method is diſtributed by others into two general kinds, *viz. natural* and *arbitrary. Natural* method is that which obſerves the order of nature, and proceeds in ſuch a manner, as that the knowledge of things which follow depends in a great meaſure on the things which go before. *Arbitrary* method leaves the order of nature, and accommodates itſelf to many purpoſes: as to treaſure up things, and retain them in the memory; to harangue and perſuade mankind to any practice in the religious or civil life; or to delight, amuſe, or entertain the mind. This kind of method is chiefly purſued in poetry and oratory.

Natural method is again ſubdivided into two kinds; the one of *reſolution,* which is that we generally uſe in our enquiry after truth. The other of *compoſition,* by which the truth, once found, is taught or imparted to others.

In the method of *reſolution,* called alſo by geometers the *analytic* method, we proceed from ſome general known truths to others, which belong to ſome particular or ſingular thing.

In the *method of compoſition,* called alſo the *ſynthetic* method, we propoſe ſome certain general truths, from which we produce particular truths.

If, in the method of reſolution, we lay down any axioms, it is not immediately in the beginning, and all together, but as they are found neceſſary in the diſquiſition: on the contrary, in the method of compoſition, they are propoſed all together in the beginning, before there is any abſolute need of them.

The two methods differ from each other, as the methods of ſearching out a genealogy, either by deſcending from the anceſtors to their poſterity, or by aſcending from the poſterity to the anceſtors: both of them have this in common, that their progreſſion is from a thing known to another unknown. Thoſe things that are known in each are ſet in the front, or firſt place, that by them we may be able to arrive at thoſe which are not known.

Dr. Watts, in his excellent Treatiſe on Logic, has compriſed the general requiſites of true method in the purſuit or communication of knowledge, under the following heads. It muſt be, 1. Safe or ſecure from error: in order to which great care ſhould be uſed in laying the foundations of a diſcourſe, or the ſcheme of our thoughts, on any ſubject; the primary and fundamental propoſitions ſhould not only be evident and true, but made familiar to the mind by dwelling on them before we proceed farther; our ground ſhould be made firm in every ſtep; and we ſhould draw up all our propoſitions and arguments with ſo much caution, and expreſs our ideas with ſuch a juſt limitation, as may preclude or anticipate any objections. 2. Plain and eaſy: for which purpoſe, we ſhould begin always with thoſe things that are beſt known and moſt obvious, and proceed by regular and eaſy ſteps to things that are more difficult; nor ſhould we affect exceſſive haſte in learning or teaching any ſcience, nor hurry at once into the midſt of it; nor again crowd too many thoughts and reaſonings into one ſentence or paragraph, beyond the apprehenſion or capacity of our readers or hearers; we ſhould alſo avoid too many ſubdiviſions; and acquire in early life a clear and eaſy way of expreſſing our conceptions. 3. Diſtinct: in order to which no needleſs heterogeneous matter ſhould be introduced; every complicated theme or idea ſhould be divided into its diſtinct ſingle parts, as far as the nature of the ſubject, and our preſent deſign, require; we ſhould call every idea, propoſition, and argument, to its proper claſs, and keep each part of the ſubject in its own place; and in the partition of our diſcourſe into diſtinct heads, take heed that particulars do not interfere with the general, nor with each other. 4. Full, or without defect: and this is neceſſary in explaining a ſubject; in enumerating its parts or properties; in aſſerting or proving any truth; in illuſtrating or arguing a point of difficulty; in drawing up a narrative; and in ſolving any difficulty. 5. Short, or without ſuperfluity: for this purpoſe, all needleſs repetitions, tedious prolixity, long parentheſes, uſeleſs explications, proofs, and refutations, and all ſcholaſtic forms, ſhould be carefully avoided. 6. Proper to the ſubject, the deſign, and the age and place in which we dwell. 7. Connected: in order to this, we ſhould keep our main deſign always in view, and preſerve an apparent tendency in all the parts of our diſcourſe towards it; the mutual relation and dependence of the ſeveral branches of our diſcourſe ſhould be ſo juſt and evident, that every part may lead onward to the next; and we ſhould acquaint ourſelves with all the proper and decent forms of tranſition from one part of the diſcourſe to another, and practiſe them as occaſion offers.

The *ſynthetic* method is only practicable in things whoſe principles we perfectly know; as in geometry, which is wholly employed in the conſideration of abſtract modes, of which our mind has clear and adequate ideas. When the inquiry is into ſubſtances, as in phyſics, we cannot make uſe of the method of *compoſition,* becauſe their kinds and intimate eſſences are unknown to us.

This method has not been by any ſo juſtly and accurately obſerved as by the mathematicians, whoſe principles are perfectly known: its laws, therefore, will be beſt drawn from their practice; for which, ſee COMPOSITION.

The ſupreme law of the philoſophical method is, to premiſe that which is neceſſary towards the underſtanding or eſtabliſhing what follows.

The mathematical and philoſophical methods are the ſame, as may be ſeen by the practice of the geometers of antiquity, who conſtantly obſerve the law here mentioned.

Several authors, as Ramus, Meſſrs. de Port-Royal, &c. have accuſed Euclid of want of method. Had theſe gentlemen attended to the ſupreme law of all true method, they would have been more cautious in their cenſures.

METHOD, *Methodus,* is more particularly uſed, in *Mathematics,* for divers particular proceſſes for ſolving problems. In this ſenſe we ſay,

METHOD *of Exhauſtions.* See EXHAUSTIONS.

METHOD *of Fluxions.* See FLUXIONS.

METHOD *de Maximis & Minimis,* &c. See MAXIMA, &c.

METHOD *of Tangents.* See TANGENTS.

METHOD *Differential,* &c. See DIFFERENTIAL.

METHOD *Exponential.* See EXPONENTIAL.

METHOD *Poriſtic.* See PORISTIC.

METHODIC SECT. See METHODISTS, and MEDICINE, *Hiſtory of.*

METHODISTS, in *Eccleſiaſtical Hiſtory,* is a denomination applied to different ſects, both Papiſts and Proteſtants.

The *Popiſh* Methodiſts were thoſe polemical doctors, of whom the moſt eminent aroſe in France towards the middle of the ſeventeenth century, in oppoſition to the Huguenots or Proteſtants. The Methodiſts, from their different manner of treating the controverſy with their opponents, may be divided into two claſſes. The one may comprehend thoſe doctors, whoſe method of diſputing with the Proteſtants was diſingenuous and unreaſonable, and who followed the examples of thoſe military chiefs, who ſhut up their troops in intrenchments and ſtrong holds, in order to cover them from the attacks of the enemy. Of this number were the Jeſuit Veron, who required the Proteſtants to prove the tenets

tenets of their church by plain passages of scripture, without being allowed the liberty of illustrating those passages, reasoning upon them, or drawing any conclusions from them; Nihusius, an apostate from the Protestant religion; the two Walenburgs, and others, who confined themselves to the business of answering objections and repelling attacks; and cardinal Richelieu, who restricted the whole controversy to the single article of the divine institution and authority of the church. The Methodists of the second class were of opinion, that the most expedient manner of reducing the Protestants to silence, was not to attack them partially, but to overwhelm them at once, by the weight of some general principle or presumption, some universal argument, which comprehended, or might be applied to all the points contested between the two churches: thus imitating the conduct of those military leaders, who, instead of spending their time and strength in sieges and skirmishes, endeavour to put an end to the war by a general and decisive action. These polemics rested the defence of popery upon prescription; the wicked lives of Protestant princes who had left the church of Rome; the crime of religious schism; the variety of opinions among Protestants, with regard to doctrine and discipline; and the uniformity of the tenets and worship of the church of Rome. To this class belong Nicole, the Jansenist doctor, the famous Bossuet, &c. Mosh. Eccl. Hist. vol. v. 8vo.

The *Protestant* Methodists form a very considerable class, principally of the lower people in this country. They sprung up about the year 1729, at Oxford, and were soon divided into two parties, the one under the direction of the two brothers, John and Charles Wesley, and the other under that of Mr. George Whitefield, who joined them in the year 1735. These leaders, and, if we except Mr. William Law, the celebrated mystic, founders of Methodism, were educated at Oxford, and received episcopal ordination; and always professed themselves advocates for the articles and liturgy of the established church: though they commonly practised the dissenting mode of worship. The appellation of Methodists is said to have been derived from the regular distribution of their time, their orderly and composed demeanour, and the supposed purity of their religious principles. Conceiving a design of forming separate communities, superior in sanctity and perfection to all other Christian churches, and impelled to a very considerable degree by a zeal of an enthusiastic and extravagant kind, they became itinerant preachers, and, being excluded from most of our churches, exercised their ministry in private houses, fields, &c. not only in Great Britain and Ireland, but also in America: thus collecting a very considerable number of hearers and proselytes, both amongst the members of the established church and the dissenters. The theological system of Mr. Whitefield and his followers is Calvinistic: that of Mr. Wesley and his disciples, Arminian; and the latter maintain the possibility of attaining sinless perfection in the present state. The subordinate teachers of both these classes of Methodists are generally men of no liberal education, and they pretend to derive their ministerial abilities from special communications of the spirit. The Methodists of both parties, like other enthusiasts, make true religion to consist principally in certain affections and inward feelings, which it is impossible to explain, but which, when analysed, seem to be mechanical in their spring and operation, and they generally maintain, that Christians will be most likely to succeed in the pursuit of truth, not by the dictates of reason, or by the aids of learning, but by laying their minds open to the direction and influence of divine illuminations and their conduct has been directed by impulses.

Such is the account given of the followers of Whitefield in Mosheim's Eccl. Hist. translated by Dr. Maclaine (vol. vi. p. 36. ed. 1811, 8vo.); but though it may be true in general, as comprehending Methodists of both descriptions, at their first rise and in their early progress, it admits, in the present state of this sect, of many exceptions; and it would be unjust and uncandid to charge upon a whole body of Christians, respectable both as to number and character, the errors in sentiment and irregularities in practice, into which the excesses of enthusiasm may have betrayed some of their number. Much as we may disapprove these errors and irregularities, truth requires us to declare from our own knowledge, that those who have passed under the denomination of Methodists have been eminently useful in awakening into consideration the unthinking, and in restraining the profligate, among the lower classes of mankind. We perceive with satisfaction a change of conduct: the idle and dissolute have become diligent and virtuous; religion finds votaries among those who were accustomed to treat it with neglect and contempt; the state of families has been amended, and the community in general, composed of individuals and of domestic associations, has derived benefit from the assiduity and zeal of the Methodists. We look forward with pleasure to a period, when, by the diffusion of knowledge among persons in the inferior stations of life, many of those who are now deemed erroneous enthusiasts will become enlightened, rational, and exemplary Christians. Having rendered this tribute of justice to the Methodists in general, we shall now proceed to give a more particular and detailed account of the two leading classes into which they have been divided.

The opinions of Mr. Whitefield, which we have already stated to have been Calvinistic, as well as his piety, recommended him to the notice of a devout peeress, the countess dowager of Huntingdon, who became his patron, and liberally promoted the erection of meeting-houses for the Calvinistic Methodists; and when her preachers could not obtain episcopal ordination, established a college at Trevecca, in Breconshire, not far from Brecknock, for the education of ministers in the Whitefieldian connection. This seminary, not being endowed, expired with the countess; but a new one was soon after established at Cheshunt, which has furnished the Methodists of this description with useful preachers.

We may here observe, that the proselytes of Whitefield were less numerous than those of Wesley; and that their association was less compact. Their ministers and places of worship were respectively supported by the different congregations, aided for a time by the liberality of the countess above-mentioned and her friends in the higher ranks of life; not, like those of the Wesleyan sect, by a general fund. The former had no annual assembly for the government of the whole body; but the latter had a regular session, under the name of a "Conference," in which the affairs and the circumstances of the confederacy were investigated, funds provided, abuses corrected, and grievances redressed. This meeting was composed of preachers chosen by the assemblies of different "districts" as representatives of the Methodist connection, and of the superintendants of the "circuits," or inferior divisions. It was at first limited to 100 of the senior itinerant preachers; but, in process of time, all the preachers were permitted to assist, if they were so inclined, or had an opportunity of attending. At first, laymen were allowed to preach; but ministers were afterwards ordained for that purpose by the clerical heads of the society. Our readers hardly need to be informed, that Wesley and some of his associates had taken orders in the church of England; and this circumstance increased their ministerial respectability in the general estimation; but it gave them no additional importance

importance in the opinion of the peculiar votaries of this connection, who were disposed to listen with profound attention to the effusions of the lowest and most illiterate mechanics. Mr. Wesley, speaking of these unlettered men, affirmed, that they had "help from God for that great work, the saving of souls from death, since he had enabled, and did enable them still, to turn many to righteousness.—Thus hath he destroyed the wisdom of the wise, and brought to nought the understanding of the prudent." Mr. Wesley introduced among his followers "agapæ," or love-meetings. Once in every quarter of a year, after the religious service of the day, a considerable number of persons, of both sexes, "broke bread" with each other. Alms were then collected for the poor members of the society. At these meetings the preachers and others related their respective "experience," and the service was enlivened by hymns, which were sung at certain intervals. These love-feasts were derived from the Moravians, with whom Mr. Wesley at first associated, but whose communion he soon renounced. In order to counteract the misconceptions which some persons might form of the character of the Methodists, Mr. Wesley stated the "distinguishing marks" of his followers. These marks, he said, were to be found, not in "their opinions of any sort," in their words and phrases, or in any desire of being "distinguished by actions, customs, or usages, of an indifferent nature, undetermined by the word of God;" nor did they lay the whole stress of religion upon any single part of it. But they were distinguished by having the love of God shed abroad in their hearts, by being always happy in God, ever resting on him, giving thanks for every thing, praying constantly with earnestness and fervour; by purifying their hearts from the lust of the flesh and of the eye, from envy and malice, from pride and petulance; by doing kind offices to neighbours and strangers, to friends and enemies; and by other fruits of a "living faith." Nothing, he added, was required by St. Paul but the faith here mentioned. By that alone could any one be justified, or accounted righteous before God; and the remission of sins could only be obtained through the merits of Christ, not by the good works or supposed deserts of individuals. Holiness of heart and life would flow from such faith; but good deeds without it would be inoperative and nugatory. No man could produce it in himself, as it was the work of omnipotence. It was the free gift of God to those who were before "ungodly and unholy, and fit only for everlasting destruction." He who received it was born again, yet was not so perfectly regenerate, as to be fully sanctified; for there would still be some struggles between the old and the new man, which would not cease before the Holy Spirit had given to the zealous Christian "a new and clean heart." He would then attain the "acmé" of sanctification, and be qualified for the society of "just men made perfect."

Among these Methodists dissentions existed at the time of the decease of their founder; but an interval of six years elapsed before their difference of sentiment produced an actual separation. The liberties of their church, and the rights of the people, formed the grounds of dispute. On pretence of giving due support to the plan of itinerancy, some leading ministers had endeavoured to obtain an exorbitant degree of power over the community and junior preachers; and they managed the conference in a way which tended to secure this power. Disgusted at these arbitrary proceedings, Mr. Kilham, and other members of the sect, applied to the general assembly for a redress of grievances, and for an admission of the laity to a proper share in the general government of the society. Repeated applications and remonstrances being wholly fruitless, and Mr. Kilham being expelled from the fraternity by the ruling party, about 5000 discontented members seceded from the connection in the year 1797, and formed independent arrangements on a popular basis. Another body of seceders, assuming the uncouth appellation of "Christian Revivalists," "claimed," says an historian of the Wesleyan sect, "a right to indulge their propensities to prayer and praise, at all times, and on all occasions." See Nightingale's "Portraiture of Methodism," cited in the last edition of Mosheim's Eccl. Hist. by Dr. Coote, vol. vi. p. 308—315. 8vo.

Before we close this article, we shall observe that Methodists of both descriptions are, in general, members of the established church; though they have been erroneously confounded with Protestant dissenters. Mr. Wesley would never allow of a separate communion, and required his followers to frequent the established church, when they had no opportunity of hearing their own preachers, and there to communicate. Of late, indeed, some alteration has taken place in this respect; and parties of the Wesleyans approach more nearly in principles and practice to Protestant dissenters. It is also well known, that the Methodists in Mr. Whitefield's connection, though intermixed with many who call themselves Dissenters, belonged for the most part to the church; and their more general departure from it was occasioned, when, at the request of the pious countess above-mentioned, episcopal ordination was refused to her ministers. Few of them yet understand or adopt the discriminating principles of Dissenters. The ministers, who have been qualified for the exercise of their functions by ordination according to the rites of the church, and who still continue in it, are in popular language called Methodists, or now, more generally, *evangelical* clergy; an appellation appropriating to themselves a distinguishing and peculiar character, which others of their own body are not disposed to allow them, and which, as some of them say, is, with respect to their sentiments and preaching, invidious and degrading. It is our province, in a work of this nature, to state facts and opinions justly and candidly as far as we are able; and we leave contending parties, both *in* and *out* of the church, to settle their differences among themselves.

METHODISTS, in *Medical History*, a title assumed by a sect of physicians at Rome, in order to distinguish themselves from the two opposite sects, the Empirics and Dogmatists, (see EMPIRIC,) with either of which they refused to arrange themselves. The Methodist physicians, as Celsus informs us, generally considered Themison as their founder, who was followed as a leader by Thessalus, and afterwards by Soranus of Alexandria, the last of whom practised at Rome, during the reigns of Trajan and Hadrian. A bold charlatan, Asclepiades, who settled at Rome about the time of the Mithridatic war, was the first, however, who maintained the principles adopted by this sect. Borrowing the doctrine of atoms laid down by Epicurus, he attempted to account for all diseases upon the obstruction to the circulation of the atoms, occasioned by two opposite states of the system, which he denominated *strictum* and *laxum*, or states of constriction and relaxation. Every disease, which exhibited obvious marks of retention, or appearances of hardness, tumefaction, or external inflammation, was ascribed to the state of constriction; and the opposite phenomena of augmented discharges, softness and diminution of bulk, to the condition of laxity. This doctrine became popular, partly in consequence of the self-confidence of its professors, and the loudness of their declamation against former systems, and partly from the precision and formality of the regimen which they prescribed: and its progress was, perhaps, not a little a little aided by the ſimplicity with which it ſeemed to explain all the phenomena of diſeaſe, and by the indolence which it ſanctioned in the practitioner; inaſmuch as it rendered all nice diſcrimination of ſymptoms, and particular inveſtigation of local diſeaſe, unneceſſary. It was enough to aſcertain the claſs in which any diſeaſe was to be arranged, and the general treatment would ſerve for all; the obſervation both of exciting and of proximate cauſes was deemed entirely ſuperfluous. "As ſoon as it was known," ſays Celſus, "to which of theſe claſſes a diſtemper belonged, if the body were bound, it muſt be opened; if it laboured under a flux, it muſt be reſtrained; and if it were of a mixed nature, the moſt urgent malady muſt be firſt oppoſed." For they were obliged to admit, in ſome caſes, the inconſiſtency of both *ſtrictum* and *laxum* occurring at the ſame time, in different organs of the body.

The abſurdity of founding the practice of medicine upon theſe very general principles has been pointed out, with his uſual force, by Celſus. He conſidered the Methodiſts as even below the Empirics, in the accuracy of their practical views: ſince the Empirics attended to many circumſtances of a diſeaſe, while the Methodiſts only obſerved the moſt obvious, and even the moſt common appearances. Like the farriers, who ſuperintend the diſeaſes of ſheep and cattle, but cannot learn from theſe dumb animals the peculiar ſymptoms of their complaints, they regard only a few, which are common to all. "Neque adjectum quicquam Empiricorum profeſſioni, ſed demtum eſt; quoniam illi multa circumſpiciunt, hi tantum facillima, et non plus quam vulgaria. Nam et hi, qui pecoribus ac pimentis medentur, cum propria cujuſque ex mutis animalibus noſſe non poſſint, communibus tantummodo inſiſtunt." (Celſ. de Medicina. *Præf.*) This intelligent writer then goes on to ſhew the inſufficiency of ſuch general indications in practice. In the ſtate of laxity, for inſtance, he remarks, "it is one thing to vomit bile, another to vomit blood, and another to reject the food; and there is much difference between a ſimple purging, and one attended with tormina; *i. e.* between a mere diarrhœa and a dyſentery; and likewiſe between a waſting from profuſe ſweats, and a mere maraſmus. And not one of theſe complaints is to be cured exactly in the ſame manner as another."

We have already pointed out the ſimilarity between this doctrine and that of the Brunonian ſyſtem, which has been the cauſe of much controverſy in our own times; the diſtinguiſhing features of which were, the reference of all diſeaſes to two oppoſite conditions of the conſtitution, *ſthenia* and *aſthenia*, or ſtrength and debility, (which might with almoſt equal propriety have been called *ſtrictum* and *laxum*,) and the conſequent excluſion of all particular inveſtigation of the minute diſtinctions in the phenomena of diſeaſes, which it encouraged. See MEDICINE, *Hiſtory of.*

The practice of the Methodiſts was particularly diſtinguiſhed by their rejection of purgative medicines; by their rigid and formal regimen, eſpecially in the methodical abſtinence which they enforced for a certain number of days; and by their copious uſe of warm ablutions, fomentations, cataplaſms, and frictions with oil, together with free bleeding, in diſeaſes aſcribed to ſtricture; and a ſimilar routine with cold drinks, and cold and corrugating applications, in diſorders attributed to laxity. An epitome of *methodiſtic* medicine has been handed down by Cælius Aurelianus, who tranſlated the original work of Soranus, which is loſt. See his treatiſe "De Morbis Acutis et Chronicis:"—alſo Le Clerc Hiſt. de la Medecine; Walker's Memoirs of Medicine.

METHODIUS, in *Biography*, a Chriſtian biſhop and martyr, who flouriſhed towards the cloſe of the third century; and unleſs there were two of the ſame name, who lived about this period, he was biſhop of ſeveral places, *viz.* of Olympus, in Lycia, of Tyre, and of Patara, &c. He is not mentioned by Euſebius in his Eccleſiaſtical Hiſtory, which has been aſcribed, not without probability, to his reſentment againſt him for having written with ſeverity againſt Origen, of whom, it is known, that Euſebius was a great admirer. There were two opinions concerning the death of this prelate; ſome ſay he ſuffered under Decius, or Valerian, and others contend, that he was one of thoſe who ſuffered in Diocleſian's perſecution. He is highly applauded by Epiphanius, Jerome, and others, by whom he is characteriſed as a learned and eloquent man, and a zealous defender of the truth. Lardner has given a pretty full account of his works, for which we refer to the third volume of the 8vo edition, 1788. This learned and candid critic ſays, that in the Remains of Methodius there are many interpretations of texts of ſcripture, which, in his opinion, do little honour to the author's judgment, and he gives inſtances in proof of this deciſion. Dr. Lardner likewiſe obſerves, that the Remains of Methodius clearly prove, that he admitted into the canon of the holy ſcriptures the four goſpels, the acts of the Apoſtles, the epiſtles of St. Paul, and the epiſtle to the Hebrews as one of them. He alſo owned as authentic the firſt epiſtle of St. Peter, and the firſt of St. John. His opinion about the reſt is not known. He quotes the Revelations as a book of ſacred ſcripture, written by John, whom he probably regarded as the apoſtle and evangeliſt. Lardner.

METHODIUS, ſurnamed the *Confeſſor*, who flouriſhed about the middle of the ninth century, was born at Syracuſe. Having received a good education, he went to Conſtantinople, where he embraced a religious life, and took up his reſidence in a monaſtery at the iſle of Chios. He was afterwards ordained prieſt by the patriarch Nicephorus, and upon the expulſion of that prelate from the ſee of Conſtantinople, was ſent by him to Rome to implore aſſiſtance from pope Paſchal in his behalf. Upon his return to Greece, after the death of that patriarch, he ſignalized himſelf by his zeal for image-worſhip, on which account he was committed to priſon, and endured many indignities for ſeveral years. He recovered his liberty completely in the year 842, and was in a ſhort time preferred to the patriarchate of the church of Conſtantinople. As ſoon as he was quietly ſettled in his ſee, he introduced the ſuperſtition of image-worſhip into the Greek church. Methodius died in the year 847. He was author of ſeveral works, among which was a "Conſtitution, or Manual for Perſons who, after having apoſtatized, returned again to the Profeſſion of the Chriſtian Faith." Moreri. Moſheim's Eccl. Hiſt.

METHONICA, in *Botany*, Juſſ. 48. Herm. Lugd. Bat. 688. t. 689, the Malabar name of the Superb Lily. See GLORIOSA.

METHUEN, in *Geography*, a town of America, in Eſſex county, Maſſachuſetts, on the N. bank of Merrimack river, between Dracut and Haverhill. It contains two pariſhes and 1253 inhabitants.

METHULLY, a town of Hindooſtan, in Guzerat; 15 miles S.W. of Gogo.

METHWOLD, a ſmall market-town in the hundred of Grimeſhoe and county of Norfolk, England, is ſituated four miles from Stoke Ferry, and 86 from London. It derived its name from its ſcite, and was anciently written Methelwalde, or Midlewolde, being the wold between Northwolde and Hockwolde. The church, which appears to have been built in the reign of Edward II., is a regular edifice with a nave, a nave, aifles, and chancel. At the weft end of the nave is a fquare tower, embattled; on this is raifed another tower of an octangular fhape; and from the latter rifes a fpire. The population of Methwold in the year 1801, according to the return then made to parliament, was 865, occupying 134 houfes. The market, which is kept on Tuefdays, was formerly confiderable, but is now almoft difufed: an annual fair is held on St. George's day. The town has been, from time immemorial, proverbially famous for its extenfive rabbit warrens.

In this parifh ftood Stevefholm or Shifham priory, which was given by William earl of Warren, in the reign of king Stephen, as a cell to the priory of Caftle Acre. At the diffolution it was granted to the family of Mundeford, and was afterwards conveyed to that of Seabright. Blomefield's Hiftory of Norfolk, vol. ii. Beauties of England, vol. xi. by J. Britton.

METI, a town of Abyffinia, near the coaft of the Red fea. N. lat. 13° 30'. E. long. 42° 30'.

METIMCUS, two iflands of America, near the coaft of Main. N. lat. 43° 50'. W. long. 68° 15'.

METIMIN, a town of Ruffia, near the Pacific ocean. N. lat. 64° 55'. E. long. 180° 34'.

METITCHE, or METTIJIAH, a plain in the territory of the city of Algiers, which commences about half a mile N.E. of the city and ftretches 50 Englifh miles in length, and 20 in breadth, as far as the branch of mount Atlas, at the foot of which lies the town of "Belida." This plain is well cultivated and well watered, and is in this refpect fuperior to the other diftricts of the kingdom. It is juftly reckoned, as Shaw fays, the garden of the whole kingdom.

METIUS, ADRIAN, in *Biography*, a celebrated Dutch mathematician, who flourifhed in the 16th and 17th centuries, was a native of Alkmaer. He purfued his ftudies at a German univerfity, where he afterwards taught the mathematics with great reputation for feveral years, and afterwards became profeffor of thofe fciences at the univerfity of Franeker. He was author of feveral books on fpherics, aftronomy, and arithmetic. He had a brother James, for whom he claimed the honour of having been the firft inventor of the telefcope; but according to Borelli's account of the difcovery of that inftrument, it is highly improbable, as it is generally believed, that Zacharias Janfen, a fpectacle maker at Middleburg, was the original inventor, (fee TELESCOPE,) and that James Metius purchafed telefcopes of Janfen's children, by which he became acquainted with their conftruction and principles.

METKERKE, ADOLPHUS VAN, was born at Bruges in 1528, and fpent the greateft part of his life in the fervice of the revolted ftates of the Low Countries, in the quality of counfellor of ftate, and envoy to the foreign potentates. In the latter ftation he was at the court of queen Elizabeth, when he died, in 1591, of grief, it was faid, on account of the lofs of his fon Nicholas, an active commander before Deventer. He was a man of great learning, and was author of the following works; "A Tranflation, with Notes, of fome Pieces of Theocritus, Bion, and Mofchus;" "Latin Poems;" "A Treatife in Latin on the true Pronunciation of the Greek Language;" "A Collection of the Proceedings at the Peace concluded at Cologne in 1579." He took a part in other works, particularly in "The Lives of the Cæfars;" "The Medals of Magna Grecia," and "The Fafti Confulares," publifhed by Goltzius.

METO, or METON, a celebrated mathematician of Athens, who flourifhed 432 B.C., was the fon of Paufanias. He obferved, in the firft year of the 87th Olympiad, the folftice at Athens, and publifhed his cycle of 19 years by which he endeavoured to adjuft the courfe of the fun and moon, and to make the folar and lunar years begin at the fame point of time. This is called the Metonic period, or cycle. It is alfo called the golden number, from its great ufe in the calendar. (See CYCLE.) It is known that Meton was living about the year 412 B.C., for when the Athenian fleet was fent to Sicily, he efcaped from being embarked on that difaftrous expedition by counterfeiting an appearance of idiotifm. Moreri.

METOCHE, Μετοχε, in the *Ancient Architecture*, a term ufed by Vitruvius, to fignify the fpace or interval between the dentils. See DENTICLES.

Baldus obferves, that, in an ancient MS. copy of that author, the word *metatome* is found for *metoche*. Hence Daviler takes occafion to fufpect, that the common text of Vitruvius is corrupted, and concludes, that it fhould not be *metoche*, but *metatome*, q. d. fection.

METOCHITA, THEODORE, in *Biography*, a modern Greek hiftorian, who flourifhed in the 13th and 14th centuries. He attained to high honours in the Conftantinopolitan empire, but in the reign of Andronicus the younger, he was banifhed and his goods confifcated. He was afterwards recalled, and ended his life in a monaftery of his own foundation, in 1332. He was a man of extenfive and very deep learning, and was entitled by his contemporaries a living library. He wrote "A Compendium of Roman Hiftory, from Julius Cæfar to Conftantine," firft publifhed with notes and a Latin verfion by Meurfius, in 1618; "A Conftantinopolitan Hiftory," in one book; "A facred Hiftory;" and "A Paraphrafe on Ariftotle's Phyfics."

METONIC CYCLE, in *Chronology*. See CYCLE, and *Golden* NUMBER.

METONYMY, Μετωνυμια, from μετα, *trans*, and ονομα, *nomen*, *name*; a rhetorical trope confifting in a tranfmutation or change of names; or a putting of the effect for the caufe, or the fubject for the adjunct; and *vice verfâ*.

The metonomy is the moft confiderable of all the tropes next to a metaphor, whether we confider its force and elegancy, or the frequent ufe of it both in fpeaking and writing. It is fometimes alfo called *tranfnominatio*, and differs not much from the hypallage.

There are four kinds of metonymies in principal ufe: the *firft*, called a metonymy of the *caufe*, when the external caufe is put for the effect; this caufe is either efficient or final. Of the former kind are fuch metonymies, where we put the inventor for the thing invented; as Bacchus for wine, Ceres for bread. Metonymies of the final caufe are fuch, by which the end in doing a thing is put for the thing done. Such is that of Virgil (Eclog. x. v. 41.), "Phillis fhould garlands crop," by which are meant flowers for making garlands. The *fecond* metonymy puts the effect for the caufe, whether the agent or only the means and inftrument: thus Virgil, Æn. vi. v. 844, calls the two Scipios the deftruction of Libya, becaufe they were the agents who effected it; and Horace, Carm. i. 1, 2. compliments Mæcenas with the titles of being his guard and honour, that is, his guardian and the author of his honour: and the author is put for his works. The *third* is, when the fubject is put for the adjunct. By fubject here, in a large fenfe of the word, may be underftood that, wherein fome other thing is contained, or about which it is converfant; as likewife the poffeffor with refpect to the thing he poffeffes, and the thing fignified when put for the fign of it: thus, in the firft of thefe ways, the feat of any faculty or affection is put for the faculty or affection itfelf; as in the phrafes, a man of a clear head or of a warm heart: the place, where any actions are performed, is put for the actions

actions done in it; the country or place of residence for the inhabitants; the time for the persons living in it: in the second way, the object is used for the person, or thing employed about it: as when Cicero, pro Mil. cap. 4. says, in time of battle, the laws, *i. e.* the judges, are silent. By the third way, we say to destroy or ruin a man, meaning not his person but his estate. In the last way, statues and pictures are called by the names of the persons whom they represent.

The *fourth* kind of metonymy is that in which the adjunct is put for the subject, which is done in the same variety of ways as the former. Thus Virgil says, (Æn. i. v. 704.) "they lie down upon purple," that is, couches dyed with purple. Also, "Hope deferred maketh the heart sick," where hope is put for the thing hoped for. Titus is thus called by Suetonius "the love and delight of mankind." Thus also, we say of a person, "He has served so many campaigns," meaning so many summers. Moreover, thus a "sceptre" is put for the regal dignity, and the "sword" for the authority of the magistrate.

Vossius adds two other species of metonymy, *viz.* of the antecedent and the consequent, which bear some analogy to the cause and effect, as the one does at least give occasion to the other. By the former, "to hear," when spoken of a superior, sometimes signifies to grant or comply with, and of an inferior to obey: by the latter it is not unusual to say, "I subscribe," or set my hand to such a thing, meaning that we assent or agree to it, &c.

METOPE, or METOPA, in *Architecture*, the square space or interval between the triglyphs, in the Doric frieze.

The word, in the original Greek, signifies the distance between one aperture or hole and another, or between one triglyph and another; the triglyphs being supposed to be solives or joists that fill the apertures. It is derived from *μετα*, *inter*, *between*, and *οπη*, *foramen*.

The ancients used to adorn these parts with carved works, or paintings representing the heads of oxen, vessels, basons, and other utensils of the heathen sacrifices.

As there is found some difficulty in disposing the triglyphs and metopes in that just symmetry which the Doric order requires; some architects make it a rule, never to use this order but in temples.

METOPE, *Semi*, is a space somewhat less than half a metope, in the corner of a Doric frieze.

Le Clerc observes, that the beauty of metopes consists in their regularity, on appearing to be perfect squares; and yet, when they are equally square, they appear to be less in height than in breadth, on account of the projecture of the little bandelet; for which reason they should be made a minute or two more in height than in breadth, in order to make their appearance uniform.

He also observes, that when the triglyphs and metopes follow each other regularly, the columns must only stand one by one; excepting those of the inner angles, which ought always to be accompanied by two others, one on each side; and here it is worth remarking, that these two columns, which accompany that of the angle, are not less necessary on account of the solidity of the building, than of the regularity of the intercolumniations.

METOPIUM, in *Botany*, a name given by Pliny to the plant which produces the gum ammoniacum. He says that the ancient Greeks called it also by this name, but in that he errs. See AMMONIAC.

METOPOSCOPY, Μετωποσκοπια, from *μετωπον*, *frons*, *forehead*, and *σκοπια*, *inspection*, of *σκεπτομαι*, *I view*, the art of discovering the temperament, inclinations, and manners of persons, by inspecting their features, and the lines in their faces, and especially of their foreheads.

Metoposcopy is no more than a branch of physiognomy; the latter taking its conjectures from all parts of the body; but both the body and the branch are extremely precarious, not to say vain.

Ciro Spontoni, who has written on the subject of metoposcopy, observes, that there are seven principal lines to be considered in the forehead; each of which has its peculiar planet. The first is the line of Saturn, the second of Jupiter, &c.

METOSIS, in *Surgery*, an amaurosis, or rather a blindness, from excessive short-sightedness, since *amaurosis* implies that the defect of sight is owing to torpor, or insensibility of the retina and optic nerve. See GUTTA *Serena*.

METRAHENNY, or MINIET RAHINÉ, in *Geography*, a town of Egypt; 6 miles S. of Gizeh.

METRAMA, a river of Naples, which rises in Calabria Ultra, and runs into the Mediterranean; 4 miles S. of Nicotera. N. lat. 38° 30'. E. long. 16° 15'.

METRE, or METER, Μετρον, in *Poetry*, denotes a system of feet of a just length. Aristides defines metre, a system of feet composed of dissimilar syllables, of a just extent. In which sense metre amounts to much the same with genus carminis, or the sort of verse, and differs from rhythm. See PROSODY.

It was during the reign of Edward VI. that metrical psalmody, in the same manner as is still practised in our parochial churches, had its beginning, or at least became general in England, by the version of Thomas Sternhold, John Hopkins, and others; which, though it now appears bald, coarse, and despicable, was then equally refined with the poetical taste of the most polite courtiers and polished scholars of the nation. But time, which has added strength and energy to the *prose* translation of the psalms, as well as other parts of scripture, and made them still more venerable, has rendered the *verse* of these translators a disgrace to our literature and religion. See PSALMODY, *Metrical*, CLEMENT MAROT, GOUDIMEL, and CLAUDE LE JEUNE.

METRE, in the *French Measures*, is the ten millionth part of a quadrant of the meridian, which is adopted as the unit of length; and from which, by multiplication and division, all other measures are derived. The length of the quadrant was computed by measuring an arc of the meridian between the parallels of Dunkirk and Barcelona, and found to be 5,130,740 French toises. This number, divided by ten millions, gives 443,296 French lines, the length of the metre, which is equal to 36.9413 French inches, or 39.3702 English inches. See MEASURE and STANDARD.

METRE, or *Meter*, a measure for oil and other liquids in Turkey. The meter weighs eight okes, or 22½lb. avoirdupois.

METRETES, the name of a measure used among the ancients, containing somewhat more than nine gallons.

METRICAL VERSES, are those consisting of a determinate number of long and short syllables; as those of the Greek and Latin poets.

Capellus observes, that the genius of the Hebrew language is incompatible with metrical poetry.

METRICE, or METRICA, among the *Ancients*, was that part of poetry employed about the quantities of syllables, feet, sorts of metre, or verse, &c.

METRO, in *Geography*, a river which traverses the duchy of Urbino, and runs into the Adriatic, N. lat. 43° 50'.

METROCELIDES, from *μητηρ*, *a mother*, and *χηλις*, *a mole*, in *Surgery*. See NÆVUS *Maternus*.

METROCOMIA, from *μητηρ*, *mother*, and *κωμη*, *town*, or *village*, a term in the *Ancient Church History*, signifying a borough,

borough, or village, that had other villages under its jurisdiction.

What a metropolis was among cities, a metrocomia was among country towns. The ancient metrocomiæ had each its chorepiscopus or rural dean, and here was his see or residence. See Metropolis and Chorepiscopus.

METROMETER, Fr., a machine to determine the time of a piece of music. It requires a pendulum, which, while a movement is performing, may be lengthened or shortened at the pleasure of the composer, till the oscillations exactly agree with the bar, or any of its accented parts. The length of the pendulum must be specified at the beginning of a piece. Many attempts at such an expedient have been made; but we believe it has never been brought to perfection: if it had in Handel's time, many of his compositions would not be frequently injured by being performed too fast or too slow, to satisfy those who remember his works performed under his own direction.

METRONOMII, Μετρονομοι, among the Athenians, officers that inspected all sorts of measures, except those of corn; there were five of them in the city, and double that number in the Pyræus, in which the greatest mart in Attica was kept.

METROPI, in *Geography*, a town of European Turkey, in the province of Livadia; 28 miles S. of Athens.—Also, a small island in the gulf of Engia; 3 miles W. of Engia.

METROPOLI, a town of the island of Crete or Candia, said to be situated on the scite of the ancient *Gortyna;* which see; 22 miles S. of Candia. N. lat. 35° 1′. E. long. 25° 4′.

METROPOLIS, Μητροπολις, from μητηρ, *mother*, and πολις, *city*, the *mother-city*, &c. the capital of a country, or province: or the principal city, and, as it were, mother of all the rest.

Metropolis is also applied to archiepiscopal churches, and sometimes to the principal, or mother-church of a city. The Roman empire having been divided into thirteen dioceses, and one hundred and twenty provinces, each diocese and each province had its metropolis, or capital city, where the proconsul, or the vicar of the empire, had his residence.

To this civil division the ecclesiastical was afterwards adapted, and the bishop of the capital city had the direction of affairs, and the pre-eminence over all the bishops of the province. His residence in the metropolis gave him the title of *metropolitan*. See Diocese.

The erection of metropolitans is referred to the end of the third century, and was confirmed by the council of Nice. Indeed archbishop Usher, and De Marca, maintain it to be an establishment of the apostles; but in vain: for it is next to certain, that the ecclesiastical government was regulated on the plan of the civil; and that it was hence the name and authority of metropolitans were given to the bishops of the capital cities of the empire, or the provinces that composed it. This is so true, that, in the contest between the bishop of Arles and the bishop of Vienne, each of whom laid claim to the metropolitanship of the province of Vienne, the council of Turin appointed, that whichever of them could prove his city to be the civil metropolis, should enjoy the title and rights of ecclesiastical metropolitan.

Nothing is more evident than the perfect equality that reigned among the primitive churches; nor does there even appear, in the first century, the smallest trace of that association of provincial churches, from which, says Mosheim, councils and metropolitans derive their origin. (See Diocese.) The order and decency of those assemblies which were called councils, and introduced towards the close of the second century, required, says this author, that some one of the provincial bishops met in council, should be invested with a superior degree of power and authority; and hence, he adds, the rights of metropolitans were derived. See Patriarchs.

Though the ecclesiastical government, however, was modelled on the political, yet, in Gaul, and some other countries, the distinctions of metropolitan and primate were not observed till very late. As the præfectus Galliæ resided by turns at Trevoux, Vienne, Arles, and Lyons, he communicated the rank and dignity of metropolitan and primate to each of them in their turn; and yet none of the Gallican bishops assumed to themselves the rights, nor even the precedence, of metropolitans. The episcopate levelled them all, and they had no regard but to the privileges of seniority. This equality lasted till the fifth century, when the contest between the bishops of Vienne and Arles was set on foot.

M. Du Pin observes, that in the provinces of Africa, excepting those of which Carthage was the metropolis, the place where the most aged bishop resided became the metropolis: the reason of which, without doubt, was this, that neither the proconsul, nor præfectus, ever fixed their residence any where.

The same author observes, also, that in Asia there were metropolises merely nominal; that is, which had no suffragan, nor any rights of metropolitans. The bishops of Nice, Chalcedon, and Berytus, had the precedence of the other bishops, and the title of metropolitans, but this, without any other prerogative besides the honour of the appellation; they themselves being subject to their metropolitans.

A metropolitan has the privilege of ordaining his suffragans; and appeals from sentences passed by the suffragans are preferred to the metropolitan. See Archbishop.

The name metropolis was originally given to those Greek cities, which had established colonies in other places; and to these certain rights or privileges belonged, partly *honorary*, and partly *profitable*. Those of the first kind principally related to religion. *E. g.* The colonies were obliged to send annually to their metropolis deputies for offering sacrifices on their behalf to the gods of the country, and to present to them their first fruits. If the sacred fire should by any accident be extinguished, the colonies could not rekindle it any where but in the prytaneum of their founders. The colonies were under an obligation to provide themselves with priests, particularly those of their tutelar deity from their metropoles. The first places in the public solemnities, their games, &c. belonged to citizens of their respective metropolis. It was also the custom for the colonies to adorn the temples of their ancient country with considerable presents, such as the spoils of enemies, trophies, statues, and other embellishments; and it was also usual for the greater number of the Greek cities to pay a yearly tribute of certain measures of grain to that of Athens. Among the profitable rights we may reckon the following: the citizens of the metropolis had power of forming alliances, contracting marriages, &c., without having their children considered as strangers; they had likewise the power of purchasing land, and other commodities, in the territory of the colonies; the rights of hospitality took place between the metropolis and its colonies; and, moreover, the metropolis had a right of appointing legislators for their colonies, establishing their form of government, and reviving certain practices that had been abolished: they might also send new citizens into their colonies, who might share in common the benefits of the ancient colonists: generals were sometimes obtained from the metropolis, and new establishments required its sanction; but the most important right was that of demanding

manding fuccour from its colonies in time of war, both of foldiers and of fhips, and affording an afylum to the citizens of the befieged metropolis. Befides thefe general privileges, fome metropoles had peculiar claims on their colonies. The metropolis, on the other hand, had certain fervices which they were required to perform on behalf of their colonies; and if they failed, the colonies were juftified in withdrawing from them their refpect and obedience. The title of metropolis was lefs regarded among the Romans; for though they multiplied their colonies, they had but one metropolis, which was Rome; and as this was the firft city of an immenfe empire, they confidered the inhabitants of colonies merely as fubjects. In general, however, they regarded as metropoles the cities which we call "capitals," and thefe were places, in which were held the general affemblies of the province, or where exifted tribunals of the laft refort.

METROPROPTOSIS, from μήτρα, *the womb*, and προπίπτειν, *to fall down*, in *Surgery*. See PROLAPSUS *Uteri*.

METROSIDEROS, in *Botany*, fo named by Dr. Solander, from μήτρα, *the pith or heart of a tree*, and σίδηρος, *iron*, alluding to the hardnefs and colour of the wood.—Sm. Tr. of Linn. Soc. v. 3. 266. Willd. Sp. Pl. v. 2. 952. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 183. Gærtn. t. 34. f. 2. and f. 9. Lamarck Illuftr. t. 421. f. 3. (Angophora; Cavan. Ic. v. 4. 21. Leptofpermum; Forft. Gen. t. 36. f. *a*—*e* and *m*—*t*.)—Clafs and order, *Icofandria Monogynia*. Nat. Ord. *Hefperideæ*, Linn. *Myrti*, Juff.

Gen. Ch. *Cal.* Perianth half fuperior, with five fpreading teeth or fegments. *Cor.* Petals five, roundifh, concave, inferted into the rim of the calyx, alternate with its fegments; rude, and often rough, at the keel externally. *Stam.* Filaments numerous, inferted into the calyx in feveral rows, thread-fhaped, much longer than the corolla; anthers fmall, roundifh, two-lobed. *Pift.* Germen in the bottom of the calyx, roundifh; ftyle fimple, angular, erect, much fhorter than the ftamens; ftigma quite fimple. *Peric.* Capfule roundifh or ovate, coated in the lower part, of three cells, and as many abrupt valves, burfting at the upper part, the partitions from the centre of the valves. *Seeds* feveral, imbricated, roundifh or oblong, inferted into the central column.

Eff. Ch. Calyx five-cleft, half fuperior. Petals five. Stamens much longer than the corolla. Stigma fimple. Capfule of three cells.

Sir Jofeph Banks and Dr. Solander firft diftinguifhed this genus from LEPTOSPERMUM and MELALEUCA; fee thofe articles. To the latter it is moft allied in habit, but differs in having diftinct and fimple ftamens. The length of thofe organs, but more efpecially the fimple, not capitate, ftigma, diftinguifhes it from *Leptofpermum*, and the habit is totally different. Moft of the fpecies are large handfome fhrubs or trees, with long or broad, moftly fmooth and entire, leaves, and fine large, white or crimfon, flowers, confpicuous for their long and copious ftamens. Thefe plants are difpofed in two fections, according to the fituation of their leaves.

Section 1. *Leaves oppofite.*

1. M. *hifpida.* Rough Metrofideros. Sm. Tr. of L. Soc. v. 3. 267. n. 1. Exot. Bot. v. 1. 81. t. 42. Ait. n. 1. (M. anomala; Vent. Malm. t. 5. M. hirfuta; Andr. Repof. t. 281. Angophora cordifolia; Cavan. Ic. v. 4. 21. t. 338.)—Leaves oppofite; heart-fhaped and clafping the ftem at their bafe. Young branches, flower-ftalks and calyx briftly.—Gathered near Port Jackfon, New South Wales, by Dr. J. White. It was raifed from feeds in England by Meffrs. Lee and Kennedy about the year 1789, and is now not very unfrequent in the more curious greenhoufes, flowering in July and Auguft. The *ftem* is ufually four or five feet high, probably much more in New Holland, rigid, branched, round, and leafy. *Leaves* evergreen, very rigid and coriaceous, harfh and fomewhat hifpid, nearly feffile, oblong, obtufe, waved, a little revolute and flightly crenate, with one rib and many crofs parallel veins; glaucous beneath: clafping the ftem with their dilated heart-fhaped bafe. The younger *branches* are downy and briftly, terminating in copious, umbellate or cymofe, large, white *flowers*, whofe ftalks and calyx are clothed with reddifh-brown, prominent, briftly hairs, like thofe of the beautiful Rofe Acacia, *Robinia hifpida*. This is one of the moft ftately plants, when in perfection, that have been procured from New Holland. Ventenat has figured fo miferable a fpecimen, that it could fcarcely be recognized.

2. M. *floribunda.* Many-flowered Metrofideros. Sm. n. 2. Ait. n. 2.—Leaves oppofite, ftalked, ovato-lanceolate. Panicle crofs-branched. Flower-ftalks umbellate.—Native of New South Wales. Sent by fir J. Banks, about 1788, to Kew, where it blooms in the greenhoufe about July and Auguft. A more fpreading, flender and fmooth *fhrub* than the preceding, with long, lanceolate, or flightly ovate, pointed, entire *leaves*, refembling thofe of an *Eucalyptus*. The *flowers* are copious, white, much fmaller than the former, in numerous fmall *umbels*, collected into large, lax, crofs-branched, occafionally hifpid, *panicles*. *Calyx* fmooth, with fharp prominent teeth.

3. M. *coftata.* Angular-fruited Metrofideros. Gærtn. v. 1. 171. t. 34. f. 2. Sm. n. 3. (Angophora lanceolata; Cavan. Ic. v. 4. 22. t. 339.)—Leaves oppofite, ftalked, linear-lanceolate, pointed, oblique. Panicle repeatedly crofs-branched. Flower-ftalks imperfectly umbellate.—Native of New South Wales. *Leaves* narrower, longer, more rigid and fhining, than the laft, as well as more oblique, or falcate. *Panicle* more irregularly and repeatedly branched, more ftout, angular, and invariably fmooth, but lefs decidedly umbellate in its ultimate divifions. *Flowers* twice as large, yellowifh-white, the ftrong angles of the *calyx* permanent in the obovate woody *fruit*.

4. M. *diffufa.* Spreading Metrofideros. Sm. n. 4. Willd. n. 4. (Melaleuca diffufa; Forft. Prod. 37. M. lucida; Linn. Suppl. 342.)—Leaves oppofite, ovate, veiny; fmooth on both fides. Panicles axillary and terminal, with oppofite flower-ftalks.—Gathered by Forfter in New Zealand, and by Nelfon in Otaheite. We are indebted to fir J. Banks for a fine fpecimen from the laft-named ifland. The *ftem* is much branched, and by the name we prefume it fpreads horizontally. *Leaves* fmooth, numerous, on fhortifh thick ftalks, ovate or obovate, one and a half inch long, with a ftrong mid-rib, and a pair of very flight evanefcent marginal ones; the crofs veins numerous, fine and reticulated. *Flowers* in denfe, level-topped panicles. *Calyx* fmooth, fhort, hemifpherical, without angles; the teeth broad and blunt. The *petals*, and long *ftamens* and *ftyle*, appear to us crimfon; the younger Linnæus judged them, by his ill-dried fpecimen, to be yellow. The valves of the ripe *capfule*, befprinkled externally with large refinous dots, rife half their length above the *calyx*, and have not the obtufe or abrupt termination obfervable in *M. coftata*. Indeed the fpecies before us, with the four or five following, fhew many indications of a generical difference from the firft three, which perhaps, if they were compared alive, might be more evident.

5. M. *villofa.* Hoary Metrofideros. Sm. n. 5. Willd. n. 5. (Melaleuca villofa; Linn. Suppl. 342, excluding the fynonym. M. æftuofa; Forft. Prod. 38. Leptofpermum collinum; Forft. Gen. 36. n. 2.)—Leaves oppofite, ovate, veiny; downy beneath. Panicles denfe, axillary and terminal.

minal, oppoſite, downy. Flowers ſeſſile, crowded.—Gathered in Otaheite by the Forſters, as well as by Mr. Archibald Menzies. The ſize and habit are like the laſt, but the fine downy hoarineſs of the *flower-ſtalks*, *calyx*, tender *branches*, and backs of the younger *leaves*, characteriſe the preſent beautiful ſpecies. The back of each little *calyx-tooth* is ſmooth, though the *petals* are externally hoary. The latter, like the very long *ſtamens* and *ſtyle*, are crimſon. The *leaves* are broadiſh-ovate, or obovate, with a ſhort, blunt, channelled point. Mr. Menzies informs us this was called *Metroſideros ſpectabilis* by the late Dr. Solander; therefore it muſt be Gærtner's t. 34. f. 9.

6. M. *florida*. Flowery Metroſideros. Sm. n. 6. Willd. n. 6. (Melaleuca florida; Forſt. Prod. 37. Leptoſpermum ſcandens; Forſt. Gen. 36. n. 1. t. 36. f. *a* — *d*.)—Leaves oppoſite, elliptic-oblong or obovate, veiny, ſmooth. Panicle denſe, terminal. Calyx turbinate, ſmooth.—Native of New Zealand. A fine ſpecies, ſmooth in every part, with long, leafy, round *branches*. *Leaves* blunt, near two inches in length. *Flowers* large and handſome, crimſon, in denſe obtuſe terminal panicles, whoſe ſtalks are uſually three-flowered. The *calyx* is remarkably elongated, ſwelling gradually upward, with a wide mouth and ſhort blunt teeth. The *ſtyle* is remarkable for its great ſize, being, like the ſtamens, above an inch long, with a very ſlightly dilated *ſtigma*, permanent. We know nothing of the *fruit* but from Forſter, who repreſents the ſeeds as ſmall and ſlender, yet he appears not to have ſeen them ripe.

7. M. *umbellata*. Umbellate Metroſideros. Cavan. Ic. v. 4. 20. t. 337.—Leaves oppoſite, lanceolate, pointed, ſmooth. Flowers in terminal ſimple umbels. Calyx turbinate, ſilky, with naked teeth. Petals oblong.—Gathered in New Zealand by Mr. Menzies, who gave us a ſpecimen by the name of *M. lucida*, of which finding no traces in authors, we adopt that of Cavanilles, who ſays his ſpecimens were gathered by Lewis Née, near the town at Port Jackſon, New South Wales. We have however never heard of it from thence by any other means. The *ſtem* is ſaid to be eight or ten feet high. The *branches* are erect, repeatedly forked, ſmooth, leafy, round, or ſlightly angular. *Leaves* one and a half or two inches long, elliptic-lanceolate, tapering at each end, ſlightly revolute, on ſhort thick ſtalks; the under ſide paleſt, moſt opaque, dotted. *Flowers* large, red, in ſimple very cloſe umbels, the ſtalks being extremely ſhort and thick. *Calyx* turbinate, much dilated upwards, very ſilky, except the teeth, which are broad, obtuſe, and naked, glandular at the back. *Petals* elliptic-oblong, twice the length of the calyx-teeth. *Stamens* and *ſtyle* thrice as long as the petals.

8. M. *glomulifera*. Cluſter-flowered Metroſideros. Sm. n. 7. Ait. n. 3.—Leaves oppoſite, ovate, reticulated with veins; downy beneath. Heads of flowers lateral, ſtalked, downy as well as the bracteas.—Gathered near Port Jackſon by the late Mr. David Burton. Mr. Brown ſent it in 1805 to Kew garden, where it bloſſoms in May and June. This ſpecies ſeems arboreſcent. The *leaves* are ovate or oblong, greyiſh, with innumerable ſmall reticulated veins; rather downy beneath. *Flowers* whitiſh, in globoſe heads. *Footſtalks*, common *flower-ſtalk*, *calyx*, and *petals*, clothed with fine hoary down. *Stamens* and *ſtyle* reddiſh.

9. M. *anguſtifolia*. Narrow-leaved Metroſideros. Sm. n. 8. Ait. n. 4. (Myrtus anguſtifolia; Linn. Mant. 74, excluding the ſynonym of Burmann.)—Leaves oppoſite, linear-lanceolate, naked. Flower-ſtalks axillary, umbellate. Bracteas lanceolate, ſmooth, deciduous.—Native of the Cape of Good Hope, from whence it was ſent by Mr. Maſſon to Kew in 1787, but has not yet flowered there. A buſhy *ſhrub*, with ſmooth, narrow, lanceolate *leaves*, two inches long, one-third of an inch broad, finely dotted on both ſides. *Footſtalks* ſhort and thick. *Flowers* numerous, ſmall, white, in oppoſite, axillary, ſtalked, compound, downy, corymboſe cluſters. *Calyx* hemiſpherical, quite ſmooth, at length decaying, its ribs only remaining round the nearly globular capſule. It is ſingular that Thunberg, who ſent perfect ſpecimens, with ripe fruit, to Linnæus, ſhould ſtill retain this plant as a *Myrtus* in his *Prodromus*, p. 87.

Section 2. *Leaves alternate.*

10. M. *ciliata*. Fringed Metroſideros. Sm. n. 9. (Melaleuca ciliata; Forſt. Prod. 38. Leptoſpermum ciliatum; Forſt. Gen. 36. n. 3. t. 36. f. *r* — *t*.)—Leaves ſcattered, imperfectly oppoſite, elliptical, obtuſe, coriaceous, ſomewhat fringed at the baſe. Corymbs terminal, hairy.—Gathered by Forſter in the iſland of New Caledonia, not in New South Wales. A low buſhy *ſhrub*, with numerous, pale, thick and rigid, oval, concave *leaves*, like thoſe of a *Buxus* or *Celaſtrus*, an inch long, more or leſs; the young ones fringed at the baſe. The ſhort thick *footſtalks* are alſo hairy while young. *Flowers* deep red, large and handſome, moſt like thoſe of our fourth, fifth, and ſeventh ſpecies, a few together at the ends of the branches, on corymboſe, ſlightly hairy ſtalks. *Calyx* ſhort, broad and depreſſed, a little hairy, its teeth oblong, fringed. *Petals* obovate, fringed, rather longer than the calyx-teeth. *Stamens* and *ſtyle* very long. *Capſule* broad, tumid, dotted with numerous prominent reſinous glands, and riſing, in three rounded lobes, much above the rim of the calyx. It is greatly to be wiſhed that this ſpecies, and ſuch as moſt reſemble it, could be obtained for the gardens of Europe.

11. M. *linearis*. Linear-leaved Metroſideros. Sm. n. 10. Ait. n. 5. (Melaleuca linearis; Schrad. Sert. Hannov. 19. t. 11.)—Leaves ſcattered, linear, channelled, acute, roughiſh, rigid. Flowers lateral, crowded, ſeſſile.—Native of New South Wales. Communicated to the Kew garden by ſir J. Banks, about the year 1788. A ſtout and rigid *ſhrub*, or ſmall *tree*, with round ſmooth *branches*. *Leaves* not unlike thoſe of ſome kinds of Fir, in their general appearance, being very numerous, ſcattered, crowded, ſeſſile, three or four inches long, ſcarcely more than a line broad, ſingle-ribbed, thick-edged, entire, roughiſh to the touch, dark green, bluntiſh with a ſmall pungent point. *Flowers* ſeſſile, in conſiderable numbers round the young branches, for the ſpace of three inches or more, ſpreading every way, the branch being continued and leafy beyond them. *Calyx* bell-ſhaped, ſmooth and even, with broad, triangular, convex, deciduous teeth. *Petals* orbicular, convex, green, often ſlightly downy. *Stamens* and *ſtyle* an inch long, prominent, of a beautiful ſhining crimſon. *Capſules* globoſe, ſomewhat depreſſed, with a very thick ſmooth coat from the body of the calyx, often crowding each other into an angular ſhape. Their little convex valves ſcarcely riſe above the even rim of the calyx.

12. M. *lanceolata*. Lanceolate Metroſideros. Sm. n. 11. Ait. n. 6. (M. citrina; Curt. Mag. t. 260. M. lophantha; Venten. Jard. de Cels, t. 69. M. marginata; Cavan. Ic. v. 4. 18. t. 332.)—Leaves alternate, lanceolate, pointed, ſmooth. Flowers lateral, crowded, ſeſſile.—Native of New South Wales. Frequent in greenhouſes. This firſt flowered in the late Marchioneſs of Rockingham's collection about the year 1790. It differs from the laſt only in foliage, the *leaves* of the preſent being truly lanceolate, about two inches in length, and half an inch broad, with a ſlender marginal rib. They are ſmooth on both ſides, plentifully dotted. *Flowers* exactly like the laſt. The *calyx* is ſometimes downy,

downy, but not ſo conſtantly as we originally thought. Every part when bruiſed is highly aromatic.—In the Tranſ. actions of the Linn. Soc. v. 9. 117, a ſuſpicion is mentioned that this and the foregoing, and even the following, may be merely varieties of one ſpecies. We have ſeen from the ſeeds of one ſingle capſule of the *lanceolata*, plants produced greatly differing in the breadth of their *leaves*, inſomuch that we are almoſt perſuaded of the former part of the poſition; but the following appears too different in other reſpects, to be confounded with either of thoſe plants. We have determined to keep them all ſeparate, for the preſent at leaſt, till Mr. Brown, who has ſeen them wild, ſhall give his opinion.

13. M. *ſaligna*. Willow-leaved Metroſideros. Sm. n. 12. Ait. n. 7. Venten. Jard. de Cels, t. 70.—Leaves alternate, lanceolate, tapering at each end, pointed. Flowers lateral, crowded, ſeſſile, ſmooth in every part.—Native of New South Wales. Sent to Kew by ſir J. Banks about the year 1788. It flowers in May and June, and differs from *M. lanceolata* in its leſs rigid *leaves*, tapering remarkably at each extremity; *flowers* not above half ſo large, with yellowiſh *ſtamens*, their *petals* not even fringed, but quite ſmooth in every part, as well as the *calyx*. To theſe marks the ingenious Ventenat added, that the ſcales of the *buds* are externally ſtriated, which is not the caſe in the *lanceolata*. Finally, the *ſaligna* has no aromatic flavour.

14. M. *viminalis*. Wand-like Metroſideros. Gærtn. v. 1. 171. t. 34. f. 4. Willd. n. 13.—Leaves alternate, linear-lanceolate. Flowers lateral, crowded, ſeſſile, downy.—Native of New Holland. Very different from the laſt, its *leaves* being more linear, and not tapering towards the extremities. The *flowers* are downy, and rather ſmaller. We have ſeen it in ſir J. Banks's herbarium only.

15. M. *capitata*. Round-headed Purple Metroſideros. Sm. n. 13. Willd. n. 14.—Leaves ſcattered, rough-edged, obovate, with a minute point. Heads of flowers terminal. Calyx and young branches hairy.—Found near Port Jackſon, New South Wales, by Dr. J. White. We have not heard of it in any garden. It ſeems rather a humble, much-branched *ſhrub;* the *branches* often cluſtered, hairy when young, round and rather ſlender; clothed with numerous, ſcattered, obovate, ſeſſile *leaves*, rough, or finely ſerrated, at the edges, from a quarter to half an inch long, with a little recurved point; their ribs three or five, not very apparent; both ſides finely dotted, the edges ſometimes fringed. *Flowers* numerous, purple, in little, round, compact, terminal heads; the *calyx* clothed with long, ſoft, hoary hairs. *Bracteas* lanceolate, fringed, deciduous. The *leaves* are ſcarcely aromatic, but rather aſtringent, with a ſlight flavour like tea.

16. M. *ericifolia*. Heath-leaved Metroſideros.—Leaves imbricated, linear, pointed, hairy; channelled above; convex beneath. Heads of flowers terminal. Bracteas feathery. Calyx ſmooth.—This hitherto nondeſcript ſpecies was gathered by Mr. A. Menzies, near King George's ſound, on the weſt coaſt of New Holland. It has the habit of an *Erica, Dioſma*, or *Phylica*. The *ſtem* is leafy, erect, with copious, ſhort, leafy, lateral *branches*. *Leaves* very numerous, crowded, about a quarter of an inch long, nearly linear, blunt, with a ſmall point, dotted, hairy, dark green, entire; convex beneath; ſlightly concave, or channelled, above. Heads of *flowers* terminal, about the ſize of the laſt. *Bracteas* lanceolate, covered at the back with long ſoft hairs, deciduous. *Calyx* turbinate, dotted, naked. The *petals* appear to be purpliſh. The *leaves* have a ſlight aſtringency, with ſome flavour of turpentine, but by no means powerful. We have not ſeen the *capſule*.

We are well aware that the habit of the two laſt ſpecies, is ſo different from the three which immediately precede them, eſpecially their infloreſcence; and all theſe together are ſo unlike thoſe deſcribed in the former ſection, that it is highly probable ſome good generic difference is to be found in their fructification. On this ſubject, as on many ſimilar ones, we muſt wait for the information of Mr. Brown, who alone has compared them all in their native country.

METROVITZ, in *Geography*, a town of Dalmatia; 6 miles N. of Narenta.

METSAMAA, a town of Sweden, in the government of Abo; 38 miles N.N.E. of Biorneborg.

METSCHOVSK, a town of Ruſſia, in the government of Kaluga; 40 miles W.S.W of Kaluga. N. lat. 54° 12'. E. long. 34 50'.

METTESHEP, or METTENSCHEP, in our *Old Writers*, an acknowledgment paid in a certain meaſure of corn; or a fine or penalty impoſed on tenants, for defaults in not doing their cuſtomary ſervice in cutting the lord's corn.

METTIJIAH, in *Geography*. See METITCHE.

METTINGEN, a town of Germany, in the county of Tecklenburg; 6 miles N. of Tecklenburgh.

METTINICK ISLAND, an iſland in the Atlantic, near the coaſt of Main. N. lat. 43° 51'. W. long. 68° 59'.

METTSECOUBE', a ſmall iſland, or perforated rock, in the Mediterranean, on the coaſt of Algiers; where, it is ſaid, Raymond Lully, in his miſſion to Africa, frequently retired to meditate; ſix miles N. of Boujeiah.

METTYCONDA, a town of Hindooſtan, in Myſore; 25 miles N. of Bangalore.

METUALES, or MUTUALES, a people of Aſia, diſperſed in great numbers all over Syria; ſo called from Mutual, a celebrated captain, who deſtroyed the current religion of the Perſians, in order to ſubſtitute Mahometaniſm inſtead of it. The Mutuales are, therefore, ſchiſmatic Mahometans. They admit the Koran as a ſacred book, and Mahomet as the firſt of prophets; and they alſo venerate Jeſus Chriſt, after the manner of the Turks. The Mutuales renounce the ſucceſſion of Mahomet, except Ali, whom they acknowledge as diſtinguiſhed among all the diſciples of the prophet by his ſkill in war, and his knowledge in letters. All forms of religion are held by them in the ſame contempt. Extreme hunger alone can conſtrain them to eat with Chriſtians.

METULÆ, a town of Sardinia; 18 miles W.N.W. of Villa d'Igleſias.

METUPETTA, a town of Hindooſtan, in the Carnatic; 30 miles S.E. of Tanjore.

METWAY HARBOUR, a bay on the S. coaſt of Nova Scotia. N. lat. 44° 10'. W. long. 64° 30'.

METYS, a word uſed by many of the ancient writers to expreſs a ſubſtance collected by bees, in order to the ſtopping up cracks and crevices in their hives.

The old authors mention three kinds of ſubſtances uſed by the bees on this occaſion, the *metys*, *piſſoceros*, and *propolis*. The moderns uſe only the latter term to expreſs every thing of this kind: the metys and piſſoceros ſeeming to have been only the ſame propolis, more or leſs mixed with wax. The ſubſtance is a reſin, of a middle conſiſtence between the hard and the fluid ones. It is uſually of a reddiſh-brown on the ſurface, and yellow within, and is collected from ſeveral trees, of which the poplar ſeems to be the principal, and the willow the next.

METZ, plur. *Metzen*, in *Commerce*, a corn meaſure in Germany. At Augſburg, 8 metzen = a ſchaf, and the metz = 4 vierlings, 16 viertels, or 64 maeſſals: 100 metzen = about 81 Wincheſter buſhels. At Vienna, 30 metzen = a muth;

muth; the metz is divided into 4 viertels = 8 achtels = 16 muhlmassels = 32 sudarmassels = 128 bechers, and it contains 3100 French cubic inches = 3753 English ditto; hence 4 metzen = 7 Winchester bushels; and a muth = 6½ English quarters nearly. See *Tab.* XXI. *of* MEASURES.

METZ, in *Geography*, a city of France, chief place of a district, and capital of the department of Moselle, situated at the conflux of the Seille and Moselle, and containing three cantons, corresponding to the three divisions of the city: the first includes 6455, and its canton 147,81 inhabitants, in 24 communes; the second contains 12,355, and its canton 14,958 inhabitants, in 11 communes; and the third part has 13,289, and its canton 15,000 inhabitants, in 4 communes. The whole extent of its territory comprehends 245 kiliometres. Metz is divided into the Old and New Town: the former is large, with narrow streets; but the houses, although built in the old style, are handsome. The New Town is also large, but more beautiful than the other. Besides its fortifications, it has three citadels. Its bishop, before the revolution, assumed the title of prince of the Roman empire; he was suffragan to the archbishop of Treves, and his diocese comprehended 613 parishes, and his revenue was 120,000 livres. Exclusively of the cathedral, it contained three chapters, sixteen parish churches, six abbies, and a college. The Jews, who are numerous in this city, have a synagogue. The country round Metz, called the Meszin, is tolerably fertile, and produces a little wheat. This was anciently a part of the kingdom of Australia; and Metz was its capital and the royal residence. When the children of Charles the Great and Louis the Pious divided the dominions of that crown, the kingdom of Lorrain arose out of the ruins of that of Australia; and about the termination of the second royal line of France, Metz, Toul, and Verdun, shook off the yoke, and put themselves, as free cities, under the protection of the emperor. In 1552, these cities placed themselves under the protection of the French, till the peace of Westphalia in 1648, when the three bishoprics were absolutely transferred to France; 30 miles S. of Luxemburg. N. lat. 49° 7'. E. long. 6° 15'.

METZERWISE, a town of France, in the department of the Moselle, and chief place of a canton, in the district of Thionville. The place contains 607, and the canton 13,439 inhabitants, on a territory of 295 kiliometres, in 45 communes.

METZONA, a town of European Turkey, in Epire; 25 miles E. of Arta.

METZU, GABRIEL, in *Biography*, one of the most ingenious painters of the Flemish school. He was born at Leyden in 1615. It is not exactly known with whom he learned the rudiments of the art, nor does it much concern us to be informed of it, as his style is entirely his own, having great completion in the finishing, with breadth and freedom quite unlike the tedious minute exactness of Gerard Dow, or still more that of Mieris.

Metzu generally painted small pictures of subjects taken from ordinary occurrences happening among the more polished class of his countrymen. A morning visit at a lady's toilette; a conversation or concert among people dressed in the best style of the time in Flanders; a gentleman stopping to drink at an inn, &c.; such are the objects which generally compose his pictures, in the execution of which one is at a loss to know whether most to admire the beauty of arrangement in the forms, the clearness and harmony of the tones, or the extreme delicacy, breadth, and truth in the execution. His works are by no means scarce in this country, and are eagerly bought at high prices.

He was severely afflicted with the stone, the effect of, and which was probably increased by, his unremitting assiduity. Having, at the age of 43, consented to undergo the operation of cutting for extraction, his constitution was found too weak to support the trial, and he did not survive it.

MEVA, or GNIEV, in *Geography*, a town of Prussia, in Pomerelia, on the Vistula; 22 miles S. of Dantzic.

MEVANGFANG, a town of Upper Siam; 115 miles N. of Porselone.

MEVELEVITES, in *Modern History*, a sort of dervises, or religious, among the Turks, so called from Meveleva, their founder. They affect to be very patient, humble, modest, and charitable; but in reality are very debauched and dishonest.

MEVIUM, a name mentioned by Fallopius and others, as given by some medical writers to the venereal disease.

MEVIUS, DAVID, in *Biography*, a learned jurist, and privy-counsellor to the king of Sweden, was employed in various negociations by Charles XI., and drew up the regulations by which the German provinces, occupied by Sweden, were to be governed. He wrote "Commentaries on the Law of Lubeck;" "Counsels or Deliberations;" and "Universal Jurisprudence."

MEULAN, in *Geography*, a town of France, in the department of the Seine and Oise, and chief place of a canton, in the district of Versailles. The place contains 2100, and the canton 12,584 inhabitants, on a territory of 130 kiliometres, in 20 communes.

MEULEBECHE, a town of France, in the department of the Lys, and chief place of a canton, in the district of Courtray. The place contains 6660, and the canton 12,506 inhabitants, on a territory of 90 kiliometres, in four communes.

MEULEN, ANTHONY FRANCIS VANDER, in *Biography*. This painter was born at Brussels in 1634. He was a disciple of Peter Snayers, a battle painter of considerable note, and his early progress gave strong promise of his future eminence.

His ingenious pictures attracted the attention of M. Colbert, the minister of Louis XIV., who induced V. Meulen to leave Brussels, and settle in Paris; and soon afterwards introduced him to the king, who appointed him to attend and paint the scenes of his military campaigns, gave him a pension of 2000 livres, and paid him besides for his performances. He made sketches of almost all the most remarkable events that occurred in these expeditions of Louis; designing upon the spot the encampments, marches, sieges, &c. of the armies; the huntings of the king; the assembling of the officers, &c.: from these he composed his pictures, which are skilfully arranged, with great bustle, animation, and spirit, and executed with a very agreeable, though not always a natural tone of colour, and with a sweet and delicate pencil. Some of his pictures exhibit uncommon skill and taste in composition. Frequently the scene he had to paint was flat and insipid, such as a marshy country before long extended walls; even these he contrived to render agreeable by his judicious management of the chiaro-scuro, and the pleasing groups which he displayed with his figures, which, though dressed in the stiff uncouth frippery of the French court of that period, are handled with so much delicacy and corresponding taste, that they never fail to please. He was particularly skilful in pourtraying the actions of the horse, of which he has left behind him a number of excellent studies, drawn with great care from nature. His pictures frequently include a great extent of country, and an immense number of objects. His perfect knowledge of perspective enabled him to manage

manage the objects and diſtances with the greateſt eaſe and effect, ſo that the eye accompanies the figures without confuſion, and aſſigns to each its due action and diſtance. He lived not beyond the age of 56, but left a great number of pictures, moſt of which are in France, but they are not very unfrequent in this country.

MEUM, in *Botany*, ſuppoſed to be the μηον of Dioſcorides, which is ſo far correct only as they are both of the umbelliferous order; for the plant deſcribed by that ancient author, is ſaid to be ſometimes two cubits high; our's is ſcarcely about a foot. See LIGUSTICUM, ſpecies twelve; for *Oethuſa* read *Aethuſa*.

MEUN, or MEUNG, JOHN DE, in *Biography*, an old French poet, was born at Meun, on the river Loire, in the year 1280. He was well acquainted with the ſtudies of the age, but poetry was his favourite purſuit, and having a turn for ſatire and lampoon, he occaſionally offended thoſe who were diſpoſed to be friendly towards him. Some court ladies, ſmarting under his laſh, once ſeized him, with the reſolution of taking their revenge, but he eſcaped the threatened puniſhment, by deſiring the moſt unchaſte to inflict the firſt blow. He died about the year 1364. By his laſt will, he directed that his body ſhould be interred in the church of the Dominicans at Paris, bequeathing to them, in the way of recompence, a heavy cheſt, which was not to be opened till after the funeral. The contents proved to be of no value whatever, which ſo enraged the holy fathers, that they ordered the dead body to be diſinterred: this coming to the knowledge of the parliament, an order was iſſued to inſiſt upon their giving it an honourable burial in their cloiſter. The principal work of this author was the continuation of the "Roman de la Roſe," begun by William de Lorris. De Meun's addition conſtitutes more than three-fourths of the whole; it is leſs poetical than the firſt part, but has more of ſatire and real manners. An edition of this poem was publiſhed by Du Freſnoy, in three vols. 12mo. to which other pieces are added. Moreri.

MEUN, in *Geography*, a town of France, in the department of the Loiret, and chief place of a canton, in the diſtrict of Orleans; 10 miles S.W. of Orleans. The place contains 4418, and the canton 9525 inhabitants, on a territory of $207\frac{1}{2}$ kiliometres, in 8 communes.

MEURJE', a town of Egypt, on the right bank of the Nile; 23 miles S. of Achmim.

MEURS, or MORS, late a principality of Germany, ſurrounded by the duchies of Juliers, Cleves, and Berg, the archbiſhopric of Cologne, and the duchy of Gueldres; about eight miles long, and as many broad. It abounds with corn, cattle, and deer. To the E. its limits are formed by the Rhine, and it is watered by ſeveral ſmaller rivers and brooks. This principality is now annexed to France, and included in the department of the Roer.

MEURS, a town of France, in the department of the Roer, and chief place of a canton, in the diſtrict of Creueldt; formerly capital of the above-mentioned principality. The town is ſmall but fortified. It has a Calviniſtic church and a Latin ſchool. The place contains 2111, and the canton 9144 inhabitants, in 15 communes; 13 miles S.E. of Gueldres. N. lat. 51° 13′. E. long. 6° 30′.

MEURSIUS, JOHN, in *Biography*, was born at Loſdun, near the Hague, in the year 1579. He was an early proficient in claſſical literature, and compoſed Latin orations and Greek verſes with facility before he was thirteen years of age. He received his academical learning at Leyden, and engaged in the education of Barneveldt's ſons; whom he afterwards accompanied on their travels. He ſpent ſome time in the ſtudy of the law at Orleans, and in 1608 was made doctor of that faculty. He viſited ſeveral courts of Europe, formed an acquaintance with many learned foreigners, and examined the moſt celebrated libraries. On his return to Holland he was appointed to the profeſſorſhip of hiſtory at Leyden in 1610, and next of the Greek language; and in the following year the ſtates of Holland nominated him their hiſtoriographer. The wretched fate of Barneveldt involved the happineſs of his friend and adherent Meurſius, and though his attention to the duties of his office had given his enemies no pretext for depriving him of his ſituation; yet they found means to render his ſituation ſo uneaſy, that he only waited for an occaſion to quit it with honour. This at length arrived, when, in 1625, he received an invitation from Chriſtiern IV., king of Denmark, to occupy the profeſſorſhip of hiſtory and politics in his new univerſity of Sora, together with the poſt of royal hiſtoriographer. Theſe offices he readily accepted, and removed to Denmark, where he continued to ſupport his high reputation, and obtained the eſteem of his ſovereign and the court. He died at Sora in the year 1639, leaving behind him a high character for profound learning, to which his various works bear ample teſtimony. His chief publications related to the language and antiquities of Greece, *viz.* "De Populis Atticis;" "Atticarum Lectionum, lib. iv.;" "Archontes Athenienſes;" "Fortuna Attica;" "Athenæ Atticæ;" "De Feſtis Græcorum;" all which have been admitted into the collections of Grævius and Gronovius. The writings of Meurſius were publiſhed collectively in twelve volumes folio, 1741. Moreri.

This learned laborious critic and antiquary, was the firſt who publiſhed the Greek text of the three books of Ariſtoxenus upon muſic, followed by the Greek treatiſes of Nichomachus and Alypius, with notes by the editor; which Meibomius has cenſured, as he has thoſe of Gogavinus, Kircher, and all thoſe who preceded him in commenting, tranſlating, or even mentioning any of the ſeven Greek writers upon muſic that are come down to us, and which he has tranſlated into Latin, and been ſeemingly more ſucceſsful in tranſlating and explaining than any other critic or commentator who has had the courage to undertake ſo difficult a taſk.

Meurſius's edition of Ariſtoxenus, Nichomachus, and Alypius, was publiſhed at Leyden, 1616, 4to. See Fabricius Bibl. Græca.

MEURTE, in *Geography*, a river of France, which riſes near St. Diey, in the department of the Voſges, and joins the Moſelle, 5 miles below Nancy.

MEURTE, or *Meurthe*, one of the ten departments of the N.E. region of France, formerly Toulois, and the S. part of Lorraine, bounded on the N. by the department of the Moſelle, on the E. by that of the Lower Rhine, on the S. by that of the Voſges, and on the W. by that of the Meuſe, in 48° 40′ N. lat. Its length is 26 French leagues, and breadth 16, and its extent in kiliometres is 6430, or 310 ſquare leagues; and the number of its inhabitants is 342,107, or, according to Haſſenfratz, 351,161; it is divided into 5 circles, and 29 cantons, and 718 communes, or, according to Haſſenfratz, 9 circles, and 74 cantons: the five circles are as follow, *viz.* Toul, including 59,689 inhabitants; Nancy, 88,384; Chateau-Salins, 50,554; Sarrebourg, 56,091; and Luneville, 87,389: its capital is Nancy. The contributions of this department, in the 11th year of the French era, were 2,681,581 fr.; and its expences charged for adminiſtration, juſtice, and public inſtruction, 348,829 fr. 33 cents. The ſoil of the plains is fertile in grain, wine, fruits,

&c.; and that of the hills is covered with wood and pastures. Here are iron mines, quarries of marble and stone, mineral springs, &c.

MEVSAK, a town of Arabia, in the province of Hedsjas; 60 miles N.E. of Vadilkova.

MEUSE, a river of France, which rises at a village called Meuse, in the department of the Upper Marne, and after being joined by various other rivers in its course, it divides into two streams, the upper one towards the N. taking the name of Merwe, which it preserves, as well as that of Meuse, till it joins the German ocean, after passing the islands of Holland and Zealand.

Meuse, one of the ten departments of the N.E. region of France, composed of Verdunois and Barrois; bounded on the N. by the duchy of Luxemburg, on the E. by the departments of the Moselle and the Meurte, on the S. by those of the Marne and Vosges, and on the W. by those of the Marne and the Ardennes, in N. lat. 49°; 33 Fr. leagues long, and 16 broad, in territorial extent 6275 kiliometres, or 318 square leagues; the number of its inhabitants is 275,898, or, according to Hassenfratz, 268,108; it is divided into 4 circles, 28 cantons, and 591 communes; or, according to Hassenfratz, into 8 circles and 79 cantons; its four circles are Bar-sur-Ornain, containing 74,168 inhabitants; Commercy, 73,103; Montmedy, 59,572; and Verdun, 69,055. Its capital is Bar-sur-Ornain. Its contributions in the eleventh year of the French era were 2,424,922 fr., and its expences amounted to 231,113 fr. 66 cents. This department is diversified with hills and plains, yielding fruits, grain, and pastures. It has mines of iron and other metals.

Meuse, *Lower*, one of the thirteen departments of the region of France, called the Reunited country, formed of a part of Gueldres, and of the territories of Liege, Maestricht, and Venloo; bounded on the N. by Brabant, on the E. by the department of the Roer, on the S. by that of the Ourthe, and on the W. by that of the Dyle, and that of the Two Nethes, in N. lat. 50° 50′: its territory comprehends 3622½ kiliometres, or 190 square leagues, and it contains 232,662 inhabitants; or, according to Hassenfratz, 216,566. It is divided into three circles, 23 cantons, and 310 communes; or, according to Hassenfratz, three circles and 30 cantons: the circles are Maestricht, including 107,410 inhabitants; Hasselt, 60,399; and Ruremond, 64,853. Its capital is Maestricht. Its contributions in the year eleven were 1,600,995 fr., and its expences 205,543 fr. 33 cents. This department is partially fertile, and yields grain, fruits, and good pastures.

MEUTANG, in *Botany*, the name of a flower much esteemed by the Chinese, which, on that account, they call the king of flowers. It is larger than our rose, and imitates its figure, only its leaves are more expanded. As its smell comes short of that of the rose, so in beauty the rose is outdone by it. It has no prickles, and its colour is a mixture of white with purple, but so as to incline most to white; yet sometimes there are found reddish and yellow ones. The tree it grows on is not unlike our alder-tree, and is cultivated throughout that large empire with great care, being covered in the summer time with a shade to defend it from the scorching heat of the sun.

MEW Island, in *Geography*, a small island in the East India sea, near the W. coast of Java; three miles N.E. of Java Head.

Mew *Islands*, a cluster of small islands on the coast of Honduras, S. of Cape Camaron.

Mew *Stone*, a small island, or round elevated rock, in the Southern India ocean, near the coast of Van Diemen's land. S. lat. 43° 46′. E. long. 146° 24′.—Also, a large rock in the English channel, on the S. coast of Devonshire, E. of the entrance into Plymouth sound; four miles S. of Plymouth. N. lat. 50° 18′. W. long. 3° 59′.

MEWAT, a hilly and woody tract of Hindoostan, lying on the S.W. of Delhi, and on the W. of Agra; confining the low country along the western side of the Jumnah river, to a (comparatively) narrow slip, and extending westwards about 130 British miles. Its length from N. to S. is about 90 miles. This tract, although situated in the heart of the empire of Hindoostan, that is, within twenty-five miles of its former capital, Delhi, is inhabited by people, who have ever been characterised as the most savage and brutal, and whose chief employment is robbery and plundering. In 1265, 100,000 of these wretches were put to the sword; and a line of forts was constructed along the foot of their hills. At the present time, says major Rennell, Mewat is so notorious a nursery for thieves and robbers, that parties of "Mewatti" are taken into pay by the chiefs of Upper Hindoostan, for the purpose of distressing the countries which are made the seat of warfare. In Acbar's division, this tract made a part of the soubahs of Delhi and Agra; but most of it was included in the latter. Mewat contains some strong fortresses, on steep or inaccessible hills; among which is Alwar, or Alvar, the citadel of Macherry Rajah. It has very often changed masters, during the contests between its native rajahs (or kauzadeh), and the Jats, the rajah of Joinagur, Nudjuff Cawn, and Madajee Sindia; and between these powers successively. Sindia has made a considerable progress in the reduction of it.

MEWING, a disorder incident to all kinds of birds; being the casting of their feathers.

MEXIA, Pedro, in *Biography*, chronicler to Charles V. is one of the few Spanish writers whose works have found their way into our language. He wrote a history of the Cæsars, which includes the German emperors, and is one of the translators of Edward Grimeston: he was author also of "Silva de varia Leccion," with the additions of its Italian and French translators in that "Treasury of ancient and modern Times," which is referred to by Grose, and of which the two parts having been published separately, are not easily to be met with together. Mexia was also the author of certain colloquies to the praise of the ass, in imitation of Lucian and Apuleius, and a history of Charles V. which he left unfinished, and which has never been edited. He was born at Seville, and died in or about the year 1552. Gen. Biog.

MEXICANO, or Adayes, a river of Louisiana, which, after pursuing a S.E. course, discharges itself into the gulf of Mexico, at Cabo du Nord, W. by S. of Ascension bay, and E. by N. of Trinity river. On its banks are rich silver mines.

MEXICO, one of the seven territories, or domains, into which the Spanish dominions in North America have been divided, sometimes improperly called *New Spain*; which is bounded on the N.W. by New Mexico, on the E. by the gulf of Mexico, on the S.E. by the isthmus of Darien, and on the S. and W. by the Pacific ocean. And though Mexico, called Old Mexico by way of distinction from New Mexico, is only a province or kingdom of New Spain, applied in its utmost extent, it is not restricted to the ancient kingdom, which extended from near the lake of Chapala in the north, to Chiapa on the river Tabasco, in the south, but includes many extensive provinces to the north. The provinces which the domain of Mexico comprehends, are

are Tabafco, Oaxaca or Guaxaca, Tlafcala, Mexico Proper, Zacatula, Mechoacan, Panuco, New Gallicia or Xalifco, and Nayarit ; fee each refpectively. Accordingly, the vice-royalty of New Spain comprehended feveral provinces, which were not fubject to the dominion of the Mexicans. The countries of Cinaloa and Sonora, that ftretch along the fide of the Vermilion fea, or gulf of California, as well as the immenfe kingdoms of New Navarre and New Mexico, which bends towards the W. and N., did not acknowledge the fovereignty of Montezuma, or his predeceffors. Thefe regions, not inferior in extent to the whole Mexican empire, have been reduced, fome of them to a greater, others to a lefs degree of fubjection, to the Spanifh yoke. They extended through the moft delightful parts of the temperate zone ; their foil is, in general, remarkably fertile ; and all their productions, whether animal or vegetable, are moft perfect in their kind. They have all a communication, either with the Pacific ocean or with the gulf of Mexico, and are watered by rivers which not only enrich them, but may become fubfervient to commerce. The peninfula of California, on the other fide of the Vermilion fea, difcovered by Cortes in the year 1536, feems to have been lefs known to the ancient Mexicans than the provinces which we have juft mentioned. On the E. of Mexico, Yucatan and Honduras are comprehended in the government of New Spain, though anciently they can hardly be faid to have formed a part of the Mexican empire. Still further E. than Honduras lie the two provinces of Cofta Rica and Veragua, which likewife belong to the vice-royalty of New Spain, but both have been fo much neglected by the Spaniards, and are of fo little value, that they merit no particular attention. Without attempting to afcertain precifely the limits of the ancient Mexican empire, which have been much controverted, we fhall give a brief geographical, hiftorical, and ftatiftical account of this empire, aided by the information which we derive from Clavigero, the abbé Raynal, Dr. Robertfon, Eftalla, &c. The name of "Anahuac," fignifying near the water, originally given to the vale of Mexico only, from the circumftance of its principal cities being fituated on fmall iflands, and on the borders of two lakes, was afterwards ufed to denominate the whole territory, now known under the appellation of New Spain. This extenfive country was then divided into the kingdoms of Mexico, Acolhuacan, Tlacopan, and Michuacan ; into the republics Tlaxcallan or Tlafcala. Chollollan, and Huexotzinco, and feveral other diftinct ftates. Thofe who wifh to know the exact fituation of thefe feveral countries may confult the tedious detail of Clavigero. The kingdom of Mexico, although the moft modern, was much more extenfive than all the other kingdoms and republics above-mentioned taken collectively. It extended towards the S.W. and S., as far as the Pacific ocean ; towards the S.E. as far as the vicinity of Quauhtemallan ; towards the E., exclufive of the diftricts of the republics, and a fmall part of the kingdom of Acolhuacan, as far as the gulf of Mexico ; towards the N., to the country of the Huaxtecas ; towards the N.W. it bordered on the barbarous Chichémicas, and the dominions of Tlacopan, on the weftern border of the lake of Tezcuco, and Michuacan, the moft wefterly kingdom of all, were its boundaries towards the weft. The whole of the Mexican kingdom, fays Clavigero, was comprehended between the fourteenth and twenty-firft degrees of N. lat., and between 271 and 283 degrees of longitude taken from the meridian of the ifland of Ferro. The fineft diftrict of this country, with regard to fituation, as well as population, was the vale of Mexico, crowned by beautiful and verdant mountains, whofe circumference, meafured at their bafe, exceeded 120 miles. A great part of the vale is occupied by two lakes, the upper one of fweet water, the lower one brackifh, communicating by a canal, and in circumference not lefs than 90 miles. Befides Mexico, Acolhuacan, and Tlacopan, there were, fays Clavigero, 40 eminent cities in this delightful vale, and innumerable villages and hamlets. The principal inland provinces to the N. were the Otomies ; to the S.W., the Matlatzincas and the Cuitlatecas ; to the S. the Tlahuicas, and the Colhuicas ; to the S.E. were the provinces of the Mixtecas, the Zapotecas, and the Chiaponecas. Towards the E. were the provinces of Tepeyacac, the Papolocas, and the Totonacas. The maritime provinces of the Mexican gulf were thofe of Coatzacualco, and Cuatlachtlan, called by the Spaniards Cotafta. The provinces on the Pacific ocean were thofe of Coliman, Zacatollan, Tototepec, Tecuantepec, and Xoconochco. The whole country of Anahuac was, generally fpeaking, well peopled. The land is, in great part, mountainous, covered with thick woods, and watered by large rivers, fome of which run into the gulf of Mexico, and others into the Pacific ocean. Here are feveral lakes which not only embellifh the country, but afford convenience to commerce. The climate of the countries of Anahuac varies according to their fituation. The maritime countries are hot, and for the moft part moift and unhealthy. The high lands, and efpecially thofe that are near to elevated mountains covered with fnow, are cold. In the other inland countries, the temperature is fuch, that the inhabitants feel neither the rigour of winter nor the heats of fummer. However, the agreeablenefs of the climate is counterbalanced by thunder-ftorms, which are frequent in fummer, and alfo by earthquakes. Some of the mountains are volcanic, and occafionally emit fire. The mountains of Anahuac abound in ores of every kind of metal, and a variety of other foffils. Different parts of the country alfo furnifh precious ftones ; and alfo feveral kinds of ftone, valuable in architecture, fculpture, and the arts. The vegetable kingdom is no lefs productive than the mineral. Hernandez, in his "Natural Hiftory," defcribes about 1200 plants, natives of this country ; fome efteemed for their flowers, fome for their fruit, fome for their leaves, fome for their roots, fome for their trunk or wood, and others for their gum, refin, oil, or juice. The country yields, by culture, the cocoa-tree, the plantain, the citron, orange, and lemon : the fruits are numerous and various, but it is needlefs to recount them all : we fhall content ourfelves with fpecifying the cocoa-nuts, vanilla, Chili or great pepper, cotton, and achiote or rocou. The country alfo produces wheat, barley, rice, peas, beans, lentils, and other leguminous vegetables. Mexico is particularly diftinguifhed by the excellence, variety, and plenty of its timber. Hernandez defcribes about one hundred fpecies of trees. It alfo affords various forts of plants, that yield profitable refins, gums, oils, and juices. The quadrupeds are horfes, affes, bulls, fheep, goats, hogs, dogs, and cats, which have all fuccefsfully multiplied, though, as fome approved writers fay, not without degenerating. The ancient quadrupeds common to Mexico and the old continent, are lions, tigers, wild cats, bears, wolves, foxes, ftags both common and white, bucks, wild goats, badgers, polecats, weazels, martins, fquirrels, rabbits, hares, otters, and rats. There are other quadrupeds common to Mexico and other regions of the new world, which we fhall not enumerate. The quadrupeds peculiarly belonging to Anahuac are the cojotl, refembling, in various refpects, the adive or chacal ; the tlacojotl, about the fize of a dog, and the largeft quadruped of thofe who live under the earth ; three fpecies of quadrupeds fimilar to dogs ; an animal belonging to the genus of wild cats, called ocotochtli ; the cajopollin, of the

 fize

fize of a common moufe; the tozan, about the bulk of an European mole, but otherwife very different; the ahuitzotl, an amphibious animal; and the hedge-hog, or porcupine of Mexico. As for birds, their number, variety, and many valuable qualities have occafioned fome authors to obferve, that as Africa is the country for beafts, fo Mexico is the country of birds. We cannot be detained in fpecifying particulars. The reptiles of Mexico may be referred to the four claffes of four-footed, and of apodes, or thofe without feet. In the lake of Chalco there are three very numerous fpecies of frogs, of three very different fizes and colours, and very common at the tables in the capital. The ferpents are very various both in fize and colour, fome poifonous and others harmlefs. The rivers, lakes, and feas of Anahuac abound with an innumerable variety of fifhes. The Mexican infects, flying, terreftrial, and aquatic, are very numerous. Scolopendras, fcorpions, fpiders, and ants are very common. The cochineal furnifhes a very confiderable article of culture and of commerce.

As to the perfons and manners of the natives we may obferve, that they are generally fomewhat above the middle fize, and well-proportioned in all their limbs: they have good complexions, narrow foreheads, black eyes, firm, regular, white teeth, thick, black, coarfe, gloffy hair, thin beards, and generally no hair upon their legs, thighs, and arms: their fkin is of an olive colour. Few deformed perfons are feen; and though they cannot be called beautiful, they do not verge to the other extreme. The young women are many of them fair and beautiful, and modeft and engaging in their manners. The conftitutions of thefe people are robuft and their health found. Some of them attain to the age of one hundred years. Although in eating they are moderate, their paffion for ftrong liquors is indulged to excefs. The ftate of civilization among the Mexicans, when they were firft known to the Spaniards, which was much fuperior to that of the Spaniards themfelves when they were firft known to the Phœnicians, that of the Gauls when firft known to the Greeks, or that of the Germans and Britons when firft known to the Romans, are fpoken of in terms of high commendation by Clavigero. He fays, we have known among the Mexicans fome good mathematicians, excellent architects, and learned divines. Of their difpofition and general conduct he feems difpofed to judge very favourably. He concludes with obferving, that the character of the Mexicans, like that of every other nation, is a mixture of good and bad: but the bad may be eafily corrected by a proper education. The ancient Mexicans, he adds, manifefted more fire, and were more fenfible to the impreffions of honour: they were more intrepid, more nimble, more active, more induftrious than thofe of modern times; but they were, at the fame time, more fuperftitious and cruel. Authors, however, have differed much in their opinion with refpect to the talents, cultivation, and character of the ancient Mexicans. Whilft they have been extravagantly extolled by fome, they have been unduly depretiated by others. Dr. Robertfon has endeavoured to fteer a mean courfe in his defcription of thefe people; neither extravagantly commending them with Clavigero, nor finking them below their proper level with De Paw and others. After their fubjection to the Spanifh crown, thofe who firft became acquainted with them were not competent judges of their talents and characters. The rapacious adventurers who formed the train of Cortes, their conqueror, were incapable of judging or pronouncing juftly concerning either their mental or moral endowments. But before we form any eftimate of the degree in which they had cultivated their minds, or made any attainments in the fciences and arts, we muft advert to their origin and the early hiftory of their eftablifhment in Mexico. The perfons who firft peopled this country, as Clavigero fuppofes, came from the more northern parts of America, where their anceftors had been fettled for many ages. The Toltecas, according to the account given us by Clavigero, are the oldeft natives of whom we have any knowledge, and that is very imperfect. It has been an opinion adopted by feveral writers, among whom we particularize Siguenza, bifhop Huet, &c. that the Mexicans, and other nations of Anahuac, were the defcendants of Naphtahim, fon of Mizraim, and nephew of Ham. Thefe, it is faid, having left Egypt not long after the confufion of tongues, travelled towards America. The reafons on which this opinion is grounded, are the conformity of thefe American nations with the Egyptians in the conftruction of pyramidal edifices, of the ufe of hieroglyphics in the mode of computing time, in their drefs, and in fome of their cuftoms, and alfo the refemblance of the word "Teul" of the Mexicans to the "Theuth" of the Egyptians. Clavigero has examined the validity of thefe arguments, and fuggefted feveral objections to which they are liable. He feems to be of opinion, that the anceftors of the nations which peopled the country of Anahuac might pafs from the northern countries of Europe into the northern parts of America, or rather from the moft eaftern parts of Afia to the moft wefterly part of America. This opinion is fupported by the general tradition of thofe nations, which afferts that their anceftors came into Anahuac from the countries of the N. and N.W.; by the remains of many ancient edifices built by thefe people in their migrations, as well as the common belief of the people in the north; and alfo, by fome ancient paintings of the Toltecas, which reprefented the migration of their anceftors through Afia and the northern countries of America. This opinion, with regard to the firft peopling of America, has derived confirmation from fome modern difcoveries, which have afcertained the near approach of the moft eafterly coaft of America to the moft eafterly part of Afia; fo that if they were not, in fome remote age, contiguous, a paffage from the one coaft to the other might be eafily effected. The quadrupeds and reptiles of the new world, it is faid, paffed thither by land; and this opinion is founded on the prefumption that the two continents were formerly united, which is adopted by Acofta, Grotius, Buffon, and other perfons of eftablifhed reputation. Clavigero conjectures, that there was formerly a great tract of land which united the now moft eaftern part of Brazil to the moft weftern part of Africa; and that this whole fpace of land may have been funk by fome violent earthquakes, leaving only fome traces of it in the ifles of Cape de Verd, Fernando de Norona, Afcenfion, St. Matthew, and others, as well as many fand banks difcovered by different navigators. However this be, the Toltecas being banifhed, as they tell us, from their own country Huehuetapallan, fuppofed to be in the kingdom of Tollan, from which they derived their name, and fituated to the N.W. of Mexico, they began their journey in the year 1 "Tecpatl," that is 596 of our era. In every place to which they came, they remained no longer than they liked it, or could be accommodated with provifions; if they determined to make a longer ftay, they erected houfes, and fowed the land with corn, cotton, and other plants, the feeds of which they carried with them for the fupply of their wants. In this migrating manner they travelled fouthward for 104 years, till they arrived at a place which they called "Tollantzinco," about 50 miles E. of the fpot, where, fome centuries after, was founded the famous city of Mexico. In this country, however, they did not

not choose to settle, although the climate was mild and the soil fruitful; but in about twenty years after, they removed about 40 miles to the W. where, along the banks of a river, they founded the city of Tollan, or Tula, after the name of their native country. That city, supposed to be the oldest in Anahuac, and one of the most celebrated in the history of Mexico, was the capital of the Toltecan kingdom, and the court of their kings. This monarchy began, as it is said, in the year 8, "Acatl," that is, 607 of the Christian era, and lasted 384 years. The Toltecas were the most celebrated people of Anahuac for their superior civilization, and skill in the arts; whence it has been common in after ages to distinguish the most remarkable artists in an honourable manner, by the appellation of Toltecas. They always lived in society, collected into cities, under the government of kings and regular laws. They were not very warlike, and less turned to the exercise of arms than to the cultivation of the arts. The nations that have succeeded them have acknowledged themselves indebted to the Toltecas for their knowledge of the culture of grain, cotton, pepper, and other most useful fruits. Besides the arts which are dictated by necessity, they practised those which administer to luxury. They had the art of casting gold and silver, and melting them to whatever form they pleased, and acquired great reputation for the cutting of all kinds of gems; but nothing raised their character so high as their having been the inventors, or at least the reformers of that system for the arrangement of time, which was adopted by all the civilized nations of Anahuac. It is said, that observing in their own country, how the solar year exceeded the civil one by which they reckoned, about six hours, they regulated it by interposing the intercalary day once in four years, which they did more than 100 years before the Christian era. Their religion, indeed, was idolatrous, and they appear, by their history, to have been the inventors of the greatest part of the mythology of the Mexicans. During the four centuries of the monarchy of the Toltecas, they multiplied exceedingly, extending their population every way in numerous and large cities, but their circumstances changed, when in the first year of the reign of Topiltzin, they suffered for want of rain and the productions of the soil, and a great part of the nation died by famine and sickness. Topiltzin died in the second year "Tecpatl," *i. e* 1052 of the vulgar era, and with him the Toltecan monarchy terminated. The wretched remains of the nation sought new abodes; some removed to Yucatan, some to Guatemala, and some remained in the kingdom of Tula, and dispersed themselves in the vale where Mexico was afterwards founded. After the destruction of the Toltecas, for the space of one century, the land of Anahuac remained solitary and almost entirely depopulated, until the arrival of the Chachemecas. These came originally from the northern countries. Their native country was called, according to their account, "Amaquemecan," where, as they say, different monarchs ruled their nation for many years. In the character of these people a certain degree of civilization was blended with many traits of barbarity. They had distinctions between the nobility and commonalty, and the plebeians were accustomed to reverence those whose birth, merit, or favour with the prince raised them above the other ranks. They dwelt together in communities in places composed, as it is probable, of poor huts; but they neither practised agriculture, nor those arts which accompany civil life. They lived on game, and fruits, and roots, which the earth spontaneously produced. Their clothing was the skins of beasts, and their arms, the bow and arrow. Their religion consisted of the simple worship of the sun, to which pretended divinity they offered herbs and flowers which they found springing in the fields. One of their princes was sent by Xolotl, his father, to survey the country: and at length Xolotl determined to establish himself in Tenayuca, a place six miles distant from the scite of Mexico towards the N., and distributed his people among the neighbouring lands. In process of time he became acquainted with several Toltecan families, encouraged intermarriages and alliances with them, and from them acquired the arts of agriculture, the manner of digging metals, the art of casting them, and also of cutting stones, spinning and weaving cotton, and of other things, which contributed to improve their means of subsistence, their clothing, their habitations, and their manners. Xolotl obtained from time to time an accession of new settlers; among whom were some of distinguished rank and character; and particularly three princes, to two of whom he gave his two daughters in marriage. When this ceremony had taken place, he divided his kingdom into several distinct states, and assigned the possession of them to his sons-in-law, and the other nobles of each nation. The population daily increased, and with it the civilization of the people; but ambition began to produce injurious effects, and Xolotl, who had hitherto governed with mildness, was obliged to recur to the punishment of some rebels with death. Upon the decease of Xolotl, he was succeeded by his son Nopaltzin II.; and upon his death his son, Tlotzin III. ascended the throne; and the succession continued in his family; according to the following list of Chachemecan kings.

Xolotl began to reign in the		12th century.
Nopaltzin	- -	13th
Tlotzin	- - -	14th
Quinatzin	- -	14th
Techotlalla	- -	14th
Ixtlilochitl	in the year	1406
Nezahualcoyotl	- -	1426
Nezahualpolli	- -	1470
Cacamatzin	- -	1516
Cuicuitzcatzin	- -	1520
Coanacotzin	- -	1520

Such is the succession of Chachemecan kings, till their monarchy terminated. The Otomies are said to have been one of the most numerous nations which settled in the country of Anahuac: they were a rude and barbarous people, and in the time of the Mexican kings they were treated as slaves. Anciently they were renowned for their dexterity in the chace; at present they traffic in coarse cloths for the dress of the other Indians. The Tarascas, who occupied the extensive, rich, and pleasant country of Michuacan, settled many cities and villages; and their kings were rivals of the Mexicans, and had frequent wars with them. These were idolatrous, but less cruel in their worship than the Mexicans. Their language is copious, sweet, and sonorous. Besides other nations, which settled in and near the vale of Mexico, the most renowned and the most signalized in the history of Mexico, were those vulgarly called the Nahuatlacas. They consisted of seven tribes, who settled in Anahuac after the Chachemecas. The Aztecas, or Mexicans, were the last people who settled in Anahuac. Till about the year 1160 of the vulgar era, they lived in Aztlan, a country situated to the N. of the gulf of California. They left their country, as it has been said, at the instigation of a person of great authority among them, to whose opinion they all paid great deference. He was led to this resolution by the fanciful interpretation of the chirping of a bird; but whatever was the motive of the migration of the Aztecas, they left their country at the time above-mentioned. After various delays in in the courfe of their peregrination, they at length arrived to the borders of the lake of Tezeuco, and near the fcite of Mexico. Here they fuffered various perfecutions and diftreffes; they engaged in a conflict with fome enemies, whom they vanquifhed, and, returning to the place of their refidence, they erected an altar to their tutelary god. When they fixed upon the fpot, on which they determined to erect their city, they built a temple to their god, and confecrated it by the effuffion of human blood. Around the fanctuary of their god they conftructed wretched huts of reeds and rufhes, being at that time deftitute of other materials; and they called it Mexico, which denomination, being taken from the name of its tutelar god, fignifies place of Mexitli, or Huitzilopochtli, as he had both thefe names. There are other etymologies of this name. (See MEXICO.) The foundation of this city was laid in the year 2, Calli, correfponding with the year 1325 of the vulgar era. Until the year 1352, the Mexican government was ariftocratical; the whole nation paying obedience to a certain body, compofed of perfons the moft refpectable for their nobility and wifdom; but at this time they imitated the example of their neighbours, and for greater fecurity from their enemies, formed their little ftate into a monarchy; and the election fell, by common confent, on Acamapitzin, who was one of the moft famous and prudent perfons then living amongft them. This monarch governed the city, which comprehended at that time the whole of his kingdom, in peace for thirty-feven years. In his time the population increafed, buildings of ftone were conftructed, and thofe canals, which ferved as well for the ornament of the city as for the convenience of its inhabitants, were begun. At his death the monarchy, which was elective, was transferred to his fon, Huitzilihuitl. After a reign of twenty years, he was fucceeded by his brother Chimalpopoca, whofe premature death made way for the election of Itzcoatl, brother to the two preceding kings, and natural fon of Acamapitzin by a flave. His government was conducted with prudence; he fubdued many neighbouring provinces; and he erected two temples, one to the goddefs Cihuacoatl, and fome time afterwards another to Huitzilopochtli, the chief Mexican divinity. After a profperous reign of thirteen years, he was fucceeded by one of his grandfons, Montezuma, who was elected with general applaufe, not lefs on account of his perfonal virtues, than the important fervices which he had performed for his country. As foon as he was fixed on the throne, he erected a famous temple in that part of the city which was called Huitznabuac; and in rearing this magnificent ftructure, he was affifted with materials and workmen by the neighbouring kings, with whom he was in alliance. He then profecuted the conquefts which he had commenced in the time of his predeceffor, and added to the Mexican empire feveral diftricts and villages. In the tenth year of his reign, correfponding to the year 1446 of the vulgar era, the city of Mexico was much damaged by an inundation from the adjacent lake; and, in order to prevent a fimilar calamity, he caufed to be conftructed a large dyke, nine miles in length, and eleven cubits in breadth, compofed of two parallel palifades, the fpace between which was entirely filled up with ftone and mud. The inundation was foon followed by a famine, which was owing to a failure of the harveft of maize. When the city had recovered itfelf from the effects of this calamity, Montezuma renewed his conquefts, and, after a diftinguifhed reign of twenty-nine years, the throne was vacated by his death in 1464, and Axayacatl was chofen to fucceed him. This king, having obtained a fignal victory over the inhabitants of a neighbouring province, in 1468, undertook the building of a temple, which he called Coatlan. The progrefs of his conquefts was interrupted by his death, in the 13th year of his reign, A.D. 1477. Tizoc, his elder brother and general of the army, was elected for his fucceffor; but his reign was fhort and undiftinguifhed by any confiderable military exploits. In the 5th year of his fovereignty he was poifoned by fome of his feudatory fubjects, A. D. 1482. During his time, the power and wealth of the crown had arrived to fuch a height, that he undertook to conftruct a temple to the tutelary god of the nation, which was to have furpaffed in magnificence all the temples of that country; he had prepared a vaft quantity of materials for this purpofe, and had actually begun the ftructure, when death interrupted his projects. Ahuitzotl, the brother of the two preceding kings, a general of the army, was chofen to fucceed him. The firft object to which his attention was directed was the completion of the temple, which had been defigned and begun by his predeceffor. This work was diligently profecuted for four years; and on occafion of his confecration he is faid to have facrificed, as fome fay, 72,344, and, according to others, 64,060 prifoners. This event happened in 1486. In the year 1498, this king projected to fupply the lake with water from a fountain at fome diftance; and in fpite of remonftrances from thofe who dreaded an inundation, he perfifted in the execution of his plan. The apprehended event occurred, and the city was deluged with the overflowing water. This deluge was fucceeded by a famine. The laft years of Ahuitzotl were paffed in conftant wars; till at length, in the year 1502, after a reign of about twenty years, he died. At the time of his death, the Mexicans were in poffeffion of all which they had at the arrival of the Spaniards. He was celebrated among his countrymen for magnificence and liberality. Having difcovered in the vale of Mexico a quarry of ftones, called tetzoutli, he embellifhed the city with fo many new and magnificent buildings, that it was already become the firft city of the new world. Upon the death of Ahuitzotl, Montezuma was elected as the 9th fovereign of Mexico. Befides the valour which he had difplayed in feveral battles, as general, he was likewife a prieft, and much venerated for his gravity, circumfpection, and religion. In order to obtain victims to be facrificed at his coronation, he entered into a war with fome neighbouring revolters; and the ceremonies exhibited on this occafion were fingularly fplendid and magnificent. Notwithftanding a folemn agreement concerted between the nobility and plebeians in a former reign for chufing the offices of ftate, Montezuma difplaced the latter, and required that all the fervants of his palace fhould be perfons of rank. Thefe were very numerous, and very fervile and obfequious. The women who attended him were alfo perfons of rank, and they lived immured in a kind of feraglio, where their conduct was vigilantly regarded; but of thefe the king retained thofe who pleafed him, and difpofed of the others as a recompence for the fervice of his vaffals. The forms and ceremonials introduced at court were additional indications of the defpotifm of Montezuma. The grandeur and magnificence of his palaces, houfes of pleafure, woods, and gardens, correfponded to every other circumftance that ferved to difplay the fplendour of his royal dignity. In Mexico, befides the feraglio for his wives, there was lodging for all his minifters and counfellors, and all the officers of his houfhold and court, and accommodation for all foreign lords and kings who arrived hither for bufinefs or pleafure. He had two houfes in the city appropriated to animals, one for birds that did not live by prey, and another for thofe of prey, quadrupeds, and reptiles. The care of the birds was committed to 300 men, befides their

their physicians, who administered remedies to their distempers. For the support of the birds of prey 500 turkies were killed daily; and the wild beasts were fed upon deer, rabbits, hares, &c. and the intestines of human sacrifices. Montezuma also collected for his amusement all irregularly formed men. All his palaces were surrounded with pleasant gardens, in which was every kind of beautiful flower, odoriferous herb, and medicinal plant. It had likewise woods enclosed with walls, and furnished with variety of game, in which he frequently sported. In one of the royal buildings was an armoury, filled with all kinds of offensive and defensive arms: and he employed a number of artificers in manufacturing these, and also artists, such as goldsmiths, mosaic-workmen, sculptors, painters, and others. One whole district consisted solely of dancing-masters, who were trained up to entertain him. His zeal for religion was no less conspicuous than his munificence. He built severel temples to his gods, and made frequent sacrifices to them, observing with punctuality the established rites and ceremonies. However, his mind was totally debased, by the vain fear of the auguries and pretended oracles of the false divinities to whom he dedicated temples. He was inexorable in punishing those who resisted his orders, or transgressed the laws of the kingdom; and he often put the integrity of his magistrates to the test by secret presents, and if he found them guilty, he inflicted severe penalties. He was an implacable enemy to idleness, every species of which he restrained or corrected. With many good qualities which he possessed, he blended a disposition to oppress his people by the imposition of heavy burdens, in order to support his own folly and extravagance, which disgusted them; notwithstanding the liberal donations which he bestowed on individuals, and particularly on his generals and ministers.

With the exception of the war against the republic of Tlascala, in which he was unsuccessful, he subdued several provinces, and extended the kingdom, as it is said, to the boundaries of Nicaragua. Montezuma, whose fate was decided after Cortes took possession of Mexico, reigned almost eighteen years, and died in June, 1520. He was succeeded by his brother, Cuitlahuatzin, or Guatimozin, as he is usually called, who ascended the throne in the beginning of July, 1520, and reigned about three months, when he was taken prisoner and strangled by order of Cortes, because he had planned a revolt after having sworn homage to the emperor Charles V., then king of Spain. His successor was Quauhtemotzin, who finished his reign on the 13th of August, 1521, having been made prisoner by the Spaniards just as Mexico was taken. His reign could not have lasted more than nine or ten months.

Although Juan de Grijalva, who was appointed by Velasquez to the command of a small expedition for discovery, consisting of four ships, and 240 volunteers, first landed in the territory of New Spain, on the island of Cozumel, E. of Yucatan, on the 3d of May, 1518, and gave the country this appellation, he returned to Cuba without making any considerable progress towards the reduction of it. Velasquez, however, hastened his preparations for a new expedition, and he appointed Fernando Cortes for the commander of it. Of this expedition, and the successful issue of it, in the capture of Mexico, and the subjugation of the Mexican empire, we have given an ample account under the article Cortes. We shall now avail ourselves of the information collected by Dr. Robertson, relating to the Mexicans and their empire, and at the same time introduce the occasional reflections of Clavigero, Estalla, and other writers. Little dependance can be placed on the accounts given of the policy and order established in the Mexican monarchy by Cortes and his adherents. The genius and manners of the people must be inferred from incidents, which they occasionally mention, rather than from their own deductions and remarks. The obscurity in which the ignorance of its conquerors involved the annals of Mexico, was augmented by the superstition of those who succeeded them. As the memory of past events was preserved among the Mexicans by figures painted on skins, or cotton cloth, or on the bark of trees, the early missionaries conceiving them to be monuments of idolatry, which ought to be destroyed, in order to facilitate the conversion of the Indians, committed them to the flames by order of Juan de Zummarage, the first bishop of Mexico. Thus the knowledge of remote events, which such rude monuments might furnish, was almost entirely lost, and no information remained concerning the ancient revolutions and policy of the empire, but such as was derived from tradition, or from some fragments of their historical paintings, that escaped the barbarous researches of Zummaraga. Tradition, it is well known, is a very unsatisfactory source of information with regard to events long since past; and the Mexican paintings, which are supposed to have served as annals of their empire, are few in number, and of ambiguous meaning; and are not worthy of that confidence, which some historians of Mexico, and particularly Clavigero, have reposed in them.

According to the report of the Mexicans themselves, their empire was not of long duration. Their country, as they relate, and as is evident from the details which we have already given, was originally possessed, rather than peopled, by small independent tribes, whose mode of life and manners resembled those of rude savages. However, at a period corresponding to the tenth century in the Christian era, several tribes moved in successive migrations from unknown regions towards the N. and N.W., and settled in different provinces of Anahuac, the ancient name of New Spain. Some of these, more civilized than the original inhabitants, began to form them to the arts of social life. At length, towards the commencement of the 13th century, the Mexicans, a people more polished than any of the former, advanced, as we have already stated, from the border of the Californian gulf, and took possession of the plains adjacent to a great lake near the centre of the country. After residing there about 50 years, they founded a town, since known by the name of Mexico, which afterwards became very considerable. The Mexicans, long after they were established in their new possessions, continued, like other martial tribes in America, unacquainted with regal dominion, and were governed in peace, and conducted in war, by such as were entitled to pre-eminence on account of their wisdom or valour. Among them, as in other states whose power and territories become extensive, the supreme authority at last centered in a single person; and when the Spaniards, under Cortes, invaded the country, Montezuma was the ninth monarch who had swayed the Mexican sceptre, not by hereditary right, but by election. Such is the traditional account given by the Mexicans themselves, of the origin and progress of their empire; and its duration appears to have been short. From the first migration of their parent tribe, they can reckon little more than 300 years: and from the establishment of monarchical government not above 130 years, as some say, or, according to others, 197 years, had elapsed. Allowing it a duration corresponding to the Spanish accounts of its civilization, it is difficult to conceive how, among a people who possessed the art of recording events by pictures; and who considered it as an essential part of their national education, to teach their children to repeat the historical songs which celebrated the exploits of their ancestors,

cestors, the knowledge of past transactions should be so limited. But adopting their own system with regard to the antiquity of their nation, it is no less difficult to account either for that improved state of society, or for the extensive dominion to which their empire had attained when it was first visited by the Spaniards. The recent origin of the Mexicans seems to be a strong presumption of some exaggeration in the splendid descriptions which have been given of their government and manners. In the history of the Mexicans some facts occur, says Dr. Robertson, that suggest an idea of considerable progress in civilization in the Mexican empire, and others which seem to indicate that it had advanced but little beyond the savage tribes around it. Our historian of America has stated these facts. The right of private property was perfectly understood, and established in its full extent. Real and moveable possessions, property in land and in goods, were accurately distinguished; and both might be transferred from one person to another by sale or barter; or both might descend by inheritance. Every person, who could be denominated a freeman, had property in land; which was held by various tenures. Some possessed it in full right, and it descended to their heirs; the title of others was attached to the office or dignity which they retained. These two modes of occupying land were deemed noble, and belonged to citizens of the highest class. But the tenure by which the great body of the people held was of a very different kind. In every district a certain quantity of land was measured out, in proportion to the number of families. This was cultivated by the joint labours of the whole; its produce was deposited in a common warehouse, and divided among them according to their respective exigencies. The members of the "Calpullee," or associations, could not alienate their share of the common estate; it was an indivisible permanent property, destined for the support of their families. Whilst the territory of the state was thus distributed, every man had an interest in its welfare, and the happiness of the individual was connected with the public security.

Another circumstance that deserves to be mentioned was the magnitude and number of their cities. In a rude state of society, men have no very operative inducements to crowd together. From choice, and also from necessity, they live dispersed. But when the Spaniards entered New Spain, they were astonished to find the natives assembled in towns which resembled in their extent those of Europe. Zempoalla, though a town of the second or third size, excited their admiration, and they compared it to cities of the greatest note in their own country. But when they afterwards became acquainted with Tlascala, Cholula, Tacuba, Tezeuco, and Mexico itself, their astonishment increased, and they were led to entertain ideas of their magnitude and populousness bordering on what is incredible. Cortes and his companions, little accustomed to estimate and compute the number of people in such cities, and strongly tempted to magnify, in order to exalt the merit of their own discoveries and conquests, might have been betrayed into error, and might have raised their descriptions considerably above the truth. Dr. Robertson therefore conceives, that abatements ought to be made in their calculations of the number of inhabitants in the Mexican cities, so that the standard of their population should be fixed much lower than they have done; nevertheless our author acknowledges that they are cities of such consequence as are not to be found but among people who have made some considerable progress in the arts of social life.

Another circumstance that ought to be regarded is the separation of professions, which is a symptom of improvement. The savage can form his bow, point his arrow, rear his hut, and hollow his canoe, without the assistance of any person more skilful than himself: but in proportion as refinement spreads, the distinction of professions increases, and they branch out into more numerous and minute subdivisions. Among the Mexicans, this separation of the arts had taken place to a very considerable degree. The functions of the mason, the weaver, the goldsmith, the painter, and of several other crafts, were carried on by different persons.

The distinction of ranks established in the Mexican empire is another circumstance that merits attention. The great body of the people was in a most humiliating state. Some, denominated "Mayeques," were attached, as it were, to the soil, and conveyed with the lands on which they were settled; others felt the utmost rigour of domestic servitude; and they were held in such low estimation, that a person who killed one of these slaves was not subjected to any punishment. Even those considered as freemen were treated by their haughty lords as beings of an inferior species. The nobles, possessed of ample territories, were divided into various classes, to which peculiar titles of honour belonged. Some of these titles descended with the lands from father to son in perpetual succession. Others were annexed to particular offices, or conferred, during life, as marks of personal distinction. The monarch, exalted above all, enjoyed extensive power, and supreme dignity. The respect attached to these different ranks corresponded to their gradation of dignity; and this respect, due from inferiors to superiors, was so established, that it incorporated with the language, and influenced its genius and idiom. The Mexican tongue abounded in terms of reverence and courtesy. It is only in societies, which time and the institution of regular government have moulded into form, that we find such an orderly arrangement of men into different ranks, and such nice attention paid to their various rights.

The political constitution of the Mexicans is an object deserving of consideration; more especially as it has been misunderstood and misrepresented by the Spaniards. The aspiring ambition of Montezuma introduced innovations upon the Mexican policy; and introduced a pure despotism. He disregarded the ancient laws, violated the privileges held most sacred, and reduced his subjects of every order to the condition of slaves. The chiefs or nobles of the first rank wished to shake off the yoke which he had imposed, and in hopes of recovering their rights, many of them courted the protection of Cortes, and joined a foreign power against their domestic oppressor. We must therefore look back beyond the reign of Montezuma in order to discover the form and genius of Mexican policy. The body of citizens, called nobility, formed the most respectable order in the state. They were of various ranks, and considerable with regard to number. Of this order there were 30 in the Mexican empire, each of whom had in his territories about 100,000 people; and subordinate to these, there were about 3000 nobles of a lower class. The territories belonging to the chiefs of Tezeuco and Tacuba were hardly inferior in extent to those of the Mexican monarch. Each of these possessed complete territorial jurisdiction, and levied taxes from their own vassals. But all followed the standard of Mexico in war, serving with a number of men in proportion to their domain, and most of them paid tribute to its monarch as their superior lord.

Traces of feudal policy, in its most rigid form, are discernible in the Mexican constitution, exhibiting its distinguishing characteristics, a nobility possessing almost independent authority, a people depressed into the lowest state of subjection, and a king entrusted with the executive power

of

of the ftate. But the jurifdiction of its crown was very limited, and all real and effective authority was retained by the Mexican nobles in their own hands. Without their confent the king could undertake no meafure of importance. At firft they elected the king, and afterwards the choice was committed to fix electors, of whom the chiefs of Tezeuco and Tacuba were two. Their choice was guided by a view to the activity and valour of their prince more than to the order of birth; fo that collaterals of mature age or diftinguifhed merit were often preferred to thofe who were nearer the throne in direct defcent. Thus the Mexicans fecured a fucceffion of able and warlike princes, who raifed their empire in a fhort period to that extraordinary height of power, which it had attained when Cortes landed in New Spain. The monarchs, reftrained at firft, gradually advanced in power and in the fplendour of their government, a ftriking inftance of which was prefented to the view of the Spaniards in Montezuma's court; but it was not merely in a parade of royalty that the Mexican monarchs exhibited their power; they manifefted it more beneficially in the order and regularity with which they conducted the internal adminiftration and police of their dominions. Their attention in providing for the fupport of government was no lefs fagacious than the actual adminiftration of it. Taxes were laid upon land, upon the acquifition of induftry, and upon commodities of every kind expofed to fale in the public markets; thefe taxes were equally laid, and, as the ufe of money was unknown, they were paid in kind. The internal police of the Mexican empire extended to the appointment of couriers for conveying intelligence, to the ftructure and government of the capital, to its accommodation with water by means of aqueducts, and to a variety of other circumftances refpecting the convenience and comfort of its inhabitants. The attention that was manifefted in regulations of this kind was fuch as polifhed nations have been late in acquiring and exercifing.

The progrefs of the Mexicans in various arts is alleged as a farther decifive proof of their fuperior refinement; but on this fubject fome Spanifh authors have been charged with exaggeration. The Mexican paintings which fome have extravagantly extolled are reprefented by others as uncouth delineations of common objects, or very coarfe images of the human and other forms, devoid of grace and propriety. In the armoury of the royal palace of Madrid, are fhewn fuits of armour, which are called Montezuma's; they are compofed of thin lacquered copper-plates. Dr. Robertfon fays, that, in the opinion of intelligent judges, thefe are evidently eaftern. Clavigero, with great ardour, and not without fome rudenefs of attack on the learned hiftorian, maintains that thefe are really Mexican; becaufe we are certain, from the teftimony of all the writers of Mexico, that thofe nations ufed fuch plates of copper in war, and that they covered their breafts, their arms and thighs with them, to defend themfelves from arrows; whereas we do not know that fuch were ever in ufe among the inhabitants of the Philippine ifles, to which Dr. R. refers them, or among any other people who had commerce with them. The Mexicans, fays Clavigero, could boaft of many inventions worthy of immortalizing their name, fuch as, befides thofe of cafting metals and mofaic works of feathers and fhells, the art of making paper, thofe of dyeing with indelible colours, fpinning and weaving the fineft hair of the rabbits and hares, making razors of a ftone called "itztli," which they manufactured with fuch expedition, that in an hour an artift could finifh more than 100, making beautiful looking-glaffes of this ftone fet with gold, the cutting and polifhing of gems, breeding of the cochineal, and making ufe of its colour, preparing of cement for the pavements of their houfes, &c. &c. Their potters were famous; and their carpenters wrought feveral kinds of wood with inftruments made of copper. They had alfo various manufactures of cloth, ufing cotton for wool, feathers for filk, with the hair of the rabbit and hare, for hat and hemp, icxotl, or mountain-palm, &c.

In the wooden prints or copper-plates of their paintings, that have been publifhed by various authors, every figure of men, quadrupeds, or birds, as well as every reprefentation of inanimate nature, is extremely rude and awkward. But though the Mexican paintings may be ranked low, as works of art, they may be regarded in a higher point of view, when confidered as the records of their country, as hiftorical monuments of its policy and tranfactions; and they become interefting objects of attention. Of their picture writing fome fingular fpecimens have been preferved. The moft valuable of thefe have been publifhed by Purchas in 66 plates, and divided into three parts. The firft contains the hiftory of the Mexican empire under its ten monarchs. The fecond is a tribute-roll, reprefenting what each conquered town paid into the royal treafury. The third is a code of their inftitutions, domeftic, political, and military. Another fpecimen of Mexican painting has been publifhed in 32 plates by the archbifhop of Toledo. The ftyle of painting is the fame in all; they reprefent *things* not *words*; exhibiting images to the eye, not ideas to the underftanding; and they may, therefore, be confidered as the earlieft and moft imperfect effay of men in their progrefs towards difcovering the art of writing. The plates already mentioned indicate fome approach to the plain and fimple hieroglyphic, where fome principal part or circumftance in the fubject is made to ftand for the whole; and the Mexicans feem alfo to have advanced farther towards the ufe of the more figurative and fanciful hieroglyphics. In order to defcribe a monarch, who had enlarged his dominions by force of arms, they painted a target ornamented with darts, and placed it between him and thofe towns which he fubdued. For the notation of numbers the Mexican painters had invented artificial marks, or "figns of convention;" by means of which they computed the years of the reigns of their kings, as well as the amount of tribute to be paid into the royal treafury. The figure of a circle reprefented unit, and in fmall numbers the computation was made by repeating it. Larger numbers were expreffed by a peculiar mark, and they had fuch as denoted all integral numbers, from 20 to 80,000. Though they had proceeded far, they had a long courfe farther to purfue from the delineation of real objects to the fimplicity and eafe of alphabetical writing.

Their mode of computing time may be confidered as a more decifive evidence of their progrefs in improvement. They divided their year into 18 months, each confifting of 20 days, amounting in all to 360. But as they obferved that the courfe of the fun was not completed in that time, they added five days to the year. Thefe were termed "fupernumerary" or "wafte" days; and as they did not belong to any month, no work was done, nor facred rite performed on them, but they were devoted wholly to feftivity and paftime. It appears, fays Clavigero, from the chronology of the Mexicans, that they not only counted 365 days to the year, but that they alfo knew the excefs of about fix hours in the folar above the civil year, and remedied the difference between them by means of 13 intercalary days, which they added to their century of 52 years. The names of their 18 months were taken both from the employments and feftivals which occurred in them, and alfo from the accidents of the feafon which attended them. The Mexicans, in order to reprefent a month, painted a circle or wheel, divided into 20 figures, fignifying 20 days. To reprefent a year they painted

painted another, which they divided into 18 figures of the 18 months, and frequently painted within the wheel the image of the moon. The century was reprefented by a wheel divided into 52 figures, or rather by four figures which were 13 times defigned. They ufed to paint a ferpent twifted about the wheel, which pointed out, by four twifts of its body, the four principal winds, and the beginnings of the four periods of 13 years. See figures of thefe wheels in Clavigero's Hift. of Mexico.

Such are the principal facts that indicate the progrefs of the Mexicans towards civilization. On the other hand, there are feveral circumftances which ferve to fhew that their character, and many of their inftitutions did not differ greatly from thofe of the other inhabitants of America. Their wars, like thofe of the rude tribes around them, were continual and ferocious; and even in their civil inftitutions we difcover traces of that barbarous difpofition which their fyftem of war infpired. Their funeral rites were not lefs fanguinary than thofe of the moft favage tribes; fo that upon the death of any diftinguifhed perfonage, efpecially the emperor, a number of his attendants were chofen to accompany him into the other world; and thefe unfortunate victims were put to death without mercy, and buried in the fame tomb. Their agriculture was in a very imperfect ftate, fo that they were often conftrained to live on the fpontaneous productions of the earth. The difficulty of rearing a numerous family, induced the Mexican women to keep the children at the breaft for feveral years, during which time they did not cohabit with their hufbands. Clavigero, however, afferts, that the Mexicans not only cultivated moft diligently all the lands of their empire, but by wonderful exertions of induftry, created to themfelves new territory for cultivation, by forming thofe floating fields and gardens on the water, which have been highly celebrated by Spaniards, and other foreigners, and are ftill the admiration of all who fail upon their lakes. They had not only, fays this writer, all the plants which were neceffary for food, for clothing, and medicine, but likewife the flowers and other vegetables which contributed folely to luxury and pleafure, were plenteoufly cultivated by them. Cortes, in a letter to Charles V., dated Oct. 1520, fays, "the multitude of inhabitants in thefe countries is fo great, that there is not a foot of land left uncultivated."

Although the Mexican empire was extenfive, the Spanifh hiftorians have enlarged it far beyond its true boundaries, and they have reprefented the dominion of Montezuma as ftretching over all the provinces of New Spain, from the N. to the fouthern ocean. But we have already ftated that many of the countries faid to have been included in the empire of the Mexicans did not belong to it. The Otomies were an uncivilized people, occupying a mountainous country. The Chechemecas, who occupied the provinces N. and W. of Mexico, were a mere nation of hunters. None of thefe recognized the Mexican monarch as their fuperior. Tlafcala, at the diftance of 21 leagues from the capital of the empire, was an independent and hoftile republic. Cholula, though ftill nearer, had been fubjected but a fhort time before the arrival of the Spaniards. Tepeaca, diftant 30 leagues from Mexico, was a feparate ftate, governed by its own laws. Mechoacan, the frontier of which extended within 40 leagues of Mexico, was a powerful kingdom, remarkable for its implacable enmity to the Mexican name. Thus limited in its extent, its various provinces had no confiderable mutual intercourfe. They had no roads for facilitating the communications of one diftrict with another; infomuch that when the Spaniards firft attempted to penetrate the country, they were under a neceffity of opening their way through forefts and marfhes. As a farther proof of the imperfection of their commercial intercourfe, it has been alleged that they had no money, or univerfal ftandard by which they might eftimate the value of commodities. Their trade was carried on by barter, and this affords an evidence of the infant ftate of their police. If by money be underftood a fign reprefenting the value of all merchandize, as Montefquieu defines it, it is certain, fays Clavigero, that the Mexicans, and all other nations of Anahuac, except the barbarous Chechemecas and Otomies, employed money in their commerce. The cacao had its fixed value, and was reckoned by numbers; but to fave the trouble of counting it, when the merchandize was of great value, and worth many thoufands of the nuts, they knew that every bag of a certain fize contained three xiquipilli, or 24,000 nuts. There were feveral fpecies of cacao, fome of which were ufed in their diet and beverages, but others were in conftant circulation as money, and ufed in no other way than in commerce. In the capital itfelf of Mexico, where from 18 to 20,000 crowns (pefos fuertes) are annually coined in gold and filver, the poor people ftill make ufe of the cacao to purchafe fmall articles in the market.

It has been further argued, that their cities, though extenfive and populous, feemed to have been better adapted for the habitations of men juft emerging from barbarity, than the refidence of a polifhed people. The ftructure of the houfes, even in Mexico, was for the moft part mean; nor does the fabric of their temples and other public edifices appear to have been fuch as entitled them to the high praifes beftowed upon them by many Spanifh authors. Their edifices in general appear to have been meanly built with turf and ftone, and thatched with reeds; nor have we any fatisfactory evidence, notwithftanding the affertion and pretended evidence of Clavigero, that they ufed lime. The great temple of Mexico was a fquare mound of earth, 90 feet wide, partly faced with ftone, with a quadrangle of 30 feet at the bafe, on which was a fhrine of the deity, probably of wood. The ftairs were made of large ftones, and confifted of 114 fteps, each a foot high; and at the eaftern extremity were raifed two towers to the height of 56 feet. Cortes affirms, that within the enclofure of the wall which encompaffed the temple, a town of 500 houfes might have ftood. Although their architecture, fays Clavigero, is not to be compared with that of the Europeans, it was certainly greatly fuperior to that of moft of the people of Afia or Africa. Who would form a comparifon between the houfes, palaces, temples, baftions, aqueducts, and roads of the ancient Mexicans, and the miferable huts of the Tartars, Siberians, Arabs, and other wretched nations which live between the Cape de Verd, and the Cape of Good Hope; or the buildings of Ethiopia, of a great part of India, and the Afiatic and African ifles, except thofe of Japan? The houfes of the emperor and thofe of the principal nobilty, it has been faid, exhibited fome elegance of defign, and a commodious arrangement of the apartments into which they were diftributed. But on the other hand it is obferved, that no remains of them are vifible, nor are there any ruins, which can juftly be confidered as monuments of their ancient magnificence. Eftalla, cited by Pinkerton, obferves, that thofe great palaces, gardens, and temples, thofe immenfe and populous cities fubject to Mexico, and whofe kings were tributary to Montezuma; that high and vaft wall which divided the Mexican empire from the republic of Tlafcala, and the other wonders related by hiftorians, fhould at leaft have left fome few ruins in teftimony of their exiftence, even granting that the Spaniards entertained the extravagant wifh of deftroying all, in order that they might

be

be obliged to construct, with great labour and expence, other edifices far inferior.

The chief remaining antiquities of the Mexicans appear to be earthen ware, in which the Indians of Guadalaxara and Mechoacan excel to this day; as the Tarascas of the Peribanes, in that of japanning, the black colour lasting as long as the wood itself, while the figures equal those of the Chinese artists, and the gilding in gold and silver is of great lustre and permanency. Dr. Robertson concludes upon the whole, that though the state of society in Mexico was considerably advanced beyond that of savage tribes, yet with respect to many particulars, the Spanish accounts of their progress in civilization and refinement appear to be highly embellished. At the same time it is allowed, that the accounts given by the Spanish writers of the Mexican power, policy, and law ought not to be rejected, or censured, as the fictions of men who wished to deceive, or who delighted in the marvellous.

With regard to religion, the Mexicans have probably been represented as more barbarous than they really were. Their religious tenets, and the rites of their worship, have been described as wild and cruel in an extreme degree. Religion, among the Mexicans, was formed into a regular system, with its complete train of priests, temples, victims, and festivals. From the genius of the Mexican religion we may form a just conclusion with respect to its influence upon the character of the people. The aspect of superstition in Mexico was gloomy and atrocious. The divinities were clothed with terror, and delighted in vengeance. The figures of serpents, tygers, and other destructive animals, decorated their temples. Fear was the only principle that inspired their votaries. Fasts, mortifications, and penance, all rigid, and many of them excruciating to an extreme degree, were the means employed to appease the wrath of their gods, and the Mexicans never approached their altars without sprinkling them with blood drawn from their own bodies. But of all offerings, human sacrifices were deemed the most acceptable. As their religious belief was blended with the implacable spirit of vengeance, and added new force to it, every captive taken in war was brought to the temple, devoted as a victim to the deity, and sacrificed with rites no less solemn than cruel. The heart and head were the portion of the gods; while the body was resigned to the captor, who, with his friends, feasted upon it. Under the impression, thus produced, the spirit of the Mexicans was unfeeling, and the genius of their religion counterbalancing the influence of policy and arts, their manners, instead of being softened, became more fierce. Although the Mexicans had some confused idea of a supreme, independent being, to whom fear and adoration were due, they represented him under no external form, because they believed him to be invisible, and they named him by the common appellation of God, in their language denominated "Teotl;" and they applied to him certain epithets expressive of grandeur and power. They called him "Ipalnemoani," *i. e.* he by whom we live, and "Tloque Nahuaque," *i. e.* he who has all in himself. But their principal worship seems to have been directed to an evil spirit, the enemy of all mankind, called "Tlacatecolototl," or, rational Owl, and they said that he often appears to men for the purpose of terrifying them or doing them an injury. They considered the human soul as immortal, allowing immortality also to the souls of brutes. They believed in a kind of transmigration, and thought that the souls of soldiers who died in battle or in captivity among their enemies, and those of women who died in labour, went to the house of the sun, to lead a life of delight; but they supposed that after four years of this glorious life, they animated birds of beautiful feathers and of sweet song, with liberty to rise again to heaven, or to descend upon the earth. The souls of inferior persons were supposed to pass into weazels, beetles, and such other meaner animals. The souls of those that were drowned, or struck by lightning, of those who died by dropsy or other diseases, went, along with the souls of children, to a cool and delightful place, the residence of "Tlalocan," where they enjoyed the most delicious repast. The abode of those who suffered any other kind of death was the "Mictlan," or hell, which they conceived to be a place of utter darkness. The Mexicans are said to have had a clear tradition, somewhat corrupted by fable, of the creation of the world, of the universal deluge, of the confusion of tongues, and of the dispersion of the people; and these events were actually represented in their pictures.

Among all the deities worshipped by the Mexicans, which were very numerous, there were 13 principal or greater gods, in honour of whom they consecrated that number. The greatest god, after the invisible god or supreme being, was "Tezcatlipoca," the god of providence, the god of the world, the creator of heaven and earth, and the maker of all things. He was always young, so that no length of years diminished his power, and to him it belonged to confer benefits on the just, and to punish the wicked with diseases and other afflictions. Among their greater gods were also the sun and moon, the god of the air, "Tlaloc," the god of water, to whom they ascribed the fertility of the earth and the protection of their temporal goods; to him they consecrated a temple, and in honour of him celebrated festivals every year; the god of fire, who was greatly revered in the Mexican empire; "Centeotl," or goddess of the earth and of corn, who had five temples in Mexico and three annual festivals; the god of hell, and his female companion, much honoured by the Mexicans; the god of night, to whom they recommended their children, that they might sleep; and "Mexitli," the god of war, most honoured by the Mexicans and regarded as their chief protector. There were other gods of commerce, fishing, hunting, &c. They had also 260 gods, to whom they consecrated as many days. The number of images by which the gods were represented and worshipped in the temples, the houses, the streets, and the woods, were almost infinite. These images were generally made of clay, and certain kinds of wood and stone; but sometimes of gold and other metals, and some of gems. The most extraordinary idol of the Mexicans was that of "Huitzilopochtli," which was formed of certain seeds pasted together by human blood. The divinity of these false gods was acknowledged by prayers, kneeling, and prostrations, with vows, fasts, sacrifices, and various rites. In their prayers they turned their faces towards the east, and their sanctuaries were constructed with their doors to the west. Annexed to the great temple, which we have already mentioned, were various other buildings; and the temples in the whole city of Mexico have been reckoned to amount to 2000, and that of the towns to 360. Each temple had its own lands and possessions, appropriated to its support. The number of the priests corresponded with that of the gods and temples; among these there were several orders and degrees, the chief of whom were two high priests, who were consulted in all affairs of moment, to whom it belonged to anoint the king after his election, and to open the breasts and take out the hearts of the human victims, at the most solemn sacrifices. The high priests of Mexico were distinguished by a tuft of cotton, hanging from their breasts, and at the principal feasts they were dressed in splendid habits, on which were represented the insignia of the god whose feast they celebrated. All the offices of religion were divided

divided among the priests; four times a day they offered incense to the idols. The dress of the Mexican priests consisted of a black cotton mantle, which they wore in form of a veil over their heads. They never shaved themselves, so that the hair of many of them reached to their legs, and it was twisted with thick cotton cords, and bedaubed with ink. The austerities and voluntary wounds of the priests, their filthy and poisonous ointments, and their other abominable rites, as they are related by Clavigero, form a system of religion, if we may thus profane the name of religion, the most execrable that ever appeared, no less dishonourable to God than pernicious to man; and it unquestionably does not warrant our entertaining any very exalted notions of their refinement and civilization. The human victims sacrificed at the consecration of two temples were 12,210!

This system is, as Pinkerton very justly observes, so totally unlike any that was ever practised in any part of Asia, that it affords a kind of presumption, either that the people were indigenal, or proceeded from Africa, in which alone (as among the Giagas) such cruelties may be traced. The Asiatic religions seem to be universally mild, and even gay, as natural in the worship of a being who is benevolence itself; while in Africa the preponderance of the evil spirit seems to have been acknowledged by many nations. It should be recollected, however, that the Manichean system was not restricted to Africa; and that the devil, or wicked demon, has had his votaries and worshippers in Asia, as well as Africa; and that the emigrants from thence might have brought the worst part of their system of worship along with them. We merely suggest, that this circumstance affords no convincing evidence with regard to the original peopling of this part of the world, or the remote origin of their ancestors. We must allow, that the Spaniards never sacrificed more victims than the Mexicans themselves devoted; and "the clamours of pretended philosophy will often be found in opposition to the real cause of humanity, which it aspires to defend. Could a change of manners have been effected without the use of the sword, it would have been highly desirable; but the design might have been as fruitless as a sermon to a tiger or a rattlesnake. The cruelties of the Spaniards must, by candour, be partly imputed to the profusion of torture and human blood, which every where met their eyes in this unhappy country; as such scenes change the very nature of man, and inflame him like the carnage of a battle." Pinkerton. It should be recollected, however, that the Spaniards had known a religion, and ought to have imbibed its spirit, which was most justly characterised by its divine founder, as "peace on earth and good will towards men."

The Mexicans performed various superstitious rites upon the birth of children, at their marriages, and at their funerals. The child was bathed, and then the diviners were consulted as to its future fortune. He was then named; the name of boys being taken from the sign of the day on which they were born, or from some circumstances attending the birth. Men had often the names of animals, and women those of flowers. The surname was acquired from their future actions. The religious ceremony of bathing was followed by a feast, when drinking was often indulged to excess. Superstition had a great share in the Mexican marriages; but nothing occurred that was inconsistent with decency or honour. Marriage between persons in the first degree of consanguinity was forbidden, unless it was between cousins. The parents were the persons who settled all marriages, and none were ever executed without their consent. The male was thought fit to form the marriage contract at the age of 20 to 22, and the female from 16 to 18 years; and before the union was concluded, the diviners were consulted, who decided on the happiness or infelicity of the proposed match. If their sentence was unpropitious, the young female was abandoned, and another sought. If the sentence was favourable, the young woman was demanded of her parents by certain women, who were held in respect and esteem. These women went at midnight to the house of the parents with a present, and demanded the damsel in a humble and respectful style. After a few days, these women repeated their visit, stating the rank and fortune of the youth, and gaining information what was her fortune. The parents then sounded the inclinations of their daughter; and in due time a decisive answer was returned. On the day appointed for the nuptials, the parents, after exhorting their daughter to a suitable conduct, led her, with a numerous company and music, to the house of her father-in-law; if noble, she was carried on a litter. The bridegroom, and her parents, received her at the gates of the house, with four torches borne by four women. At meeting, the bride and bridegroom offered incense to each other; and the bride was led by him to the hall or chamber prepared for the nuptials. They were then seated on a mat, and a priest tied a point of the gown of the bride to the mantle of the bridegroom, and in this ceremony the matrimonial contract chiefly consisted. They then offered copal to their gods, and exchanged presents with each other. This ceremony was followed with a repast, at which the bride and bridegroom gave some food to each other, and to their guests; and after the exhilaration occasioned by drinking, a dance took place; and the married pair remained in the chamber, and continued there four days; which were passed in prayer and fasting, being dressed in new habits, and adorned with certain ensigns of the gods of their nation. The marriage bed was adjusted by the priest, and the consummation of the marriage did not take place till the fourth night. On the ensuing morning they bathed and put on new dresses, and those who had been invited adorned their heads with white, and their hands and feet with red feathers. The ceremony was concluded with making presents of dresses to the guests; and on that day the mats, canes, &c. were carried to the temple. In the Mexican empire, polygamy was allowed.

The funeral rites were more superstitious than any others, and certain persons of advanced years were appointed for the conducting of them. Having clothed the body of the deceased in a habit appropriate to his former profession or business, they gave him a jug of water, and pieces of paper with instructions, adapted to his journey into the other world. They also killed a domestic quadruped, which was to be his companion. This they buried or burned together with the body of his master. The ashes were collected and deposited in a pot, together with a valuable gem: the earthen pot was deposited in a ditch, and at the interval of fourscore days, they made oblations of bread and wine over it. At the death of kings, lords, or persons of high rank, other ceremonies were practised, for the detail of which we must refer to Clavigero; merely observing, that the bodies of the deceased were generally burned, and that the ashes of kings and lords were usually deposited in the towers of the temples.

To the education of their youth, the Mexicans paid particular attention; they are habituated from their earliest age to industry, virtue, and the forms of religion; truth was inculcated by express precepts, and the violation of it severely punished, and reverence for their parents and aged persons was sedulously inculcated. Besides their domestic education, children were sent to public schools, situated near the temples, and there they were instructed for three years in religion and good customs. Adultery among the Mexi-

cans

cans was always punifhed with death; nor was any divorce allowed without the permiffion of the judges. Thofe who were guilty of inceft or unnatural crimes were hanged; and incontinence was feverely punifhed; but for fimple fornication no punifhment was prefcribed. The penalty annexed to theft in flighter cafes was mere reftitution, but in concerns of greater value, flavery. A perfon who robbed in the market place was there baftinadoed to death. Hanging was the punifhment of tutors and guardians who did not give a good account of the eftates of their pupils, and alfo of thofe who fquandered away their patrimony in vices. Drunkennefs in youth was a capital crime, and in advanced years it was punifhed with feverity; and in cafe of a nobleman, it incurred forfeiture of office and rank, and entailed infamy. The prifoners of war were generally facrificed to their gods; and flaves were allowed to poffefs fome property, nor was flavery entailed upon their defcendants. Neceffitous parents might procure relief by the fale of their children, and any freeman might fell himfelf for the fame purpofe.

The higheft military dignity among the Mexicans, was that of a general of the army; and in order to encourage a military fpirit, they rewarded the fervices of warriors with one of the three orders, called by names which denoted princes, eagles, and tigers. When they went to war, different perfons from the king to thofe of inferior rank were diftinguifhed by peculiar badges. The defenfive arms were fhields of different forms; breaft-plates of cotton, arrow-proof, and other armour for the defence of other parts of their bodies; the officers and nobles had a beautiful plume of feathers on their heads; but the common foldiers were entirely naked, except a girdle round the middle. The offenfive arms of the Mexicans, were arrows, flings, clubs, fpears, pikes, fwords and darts. They had alfo ftandards and mufical inftruments proper for war. Previoufly to a declaration of war, the alleged caufe of it was fubmitted to the judgment of the fupreme council, and before it commenced, the enemy was apprized of it. The king, or the general, gave the fignal for action by the beat of a drum; and the firft onfet was furious; but their great aim was not to kill, but to make prifoners for facrifices when the battle was terminated. The victors celebrated their conqueft with great rejoicings, and rewarded the officers and foldiers who had taken prifoners. Before any fiege was begun, the citizens removed their children, women, and fick perfons to a place of fecurity in the mountains. For the defence of their cities, they ufed various kinds of fortification, fuch as walls and ramparts, breaft-works, palifadoes, ditches, and entrenchments; but the moft fingular fortifications of Mexico in particular were its temples, and efpecially the greater temple, which refembled a citadel. The Mexicans, though fond of war, are faid to have addicted themfelves to the arts of peace, and particularly to the cultivation of the earth. Although they had no ploughs nor oxen, nor any other animals proper to be employed in agriculture, they fupplied the want of them by labour and induftry. In the operations of the field, the men were affifted by the women; the former being employed in occupations that required the greateft exertion, and the latter in the lighter and more eafy employments. In their farm-yards they had threfhing floors and granaries; and of the latter fome were fo large as to contain 5 or 6000, or fometimes more, fanegas of maize. The Mexicans were alfo well fkilled in the cultivation of gardens, both for ufe and for pleafure. They were likewife attentive to the prefervation of their woods, which ferved for fuel, for building, and for the diverfion of their king, in the purfuit of game. They alfo paid particular attention to the breeding of animals. Fifhing, hunting, agriculture, and the arts, furnifhed the Mexicans with feveral branches of commerce. Merchandizes were fold in their fairs and markets by number and meafure; but they are faid not to have ufed weights. Their markets were fubject to various regulations for the prevention of frauds, and for fecuring to the king his revenue. For the convenience of merchants, Clavigero fays, that they had public roads, bridges for croffing their rivers, and houfes of accommodation in the mountains and uninhabited places. Their failing veffels were guided merely by oars, and were of various fizes; and many of them were made of a fingle trunk of a tree. Some ancient hiftorians, probably inclined to exaggerate, fay, that the number of thofe which continually traverfed the Mexican lake exceeded 50,000. They had alfo for the convenience of navigating their lakes and rivers, platforms or floats of folid canes, which were tied firmly on large, hard, and empty gourds. The maritime commerce of the Mexicans was very inconfiderable. The commerce of the Mexicans, it is faid, was little embarraffed or impeded by the variety of languages which were fpoken in thofe countries; for the Mexican tongue was the moft prevalent, and was every where underftood. This language, fays Clavigero, is entirely deftitute of the confonants B, D, F, G, R, and S, and abounds with L, X, T, Z, T *l*, and T z; but although the letter L is fo familiar to this language, there is not a fingle word that begins with this confonant; nor is there a word of an acute termination, except fome vocatives. Almoft all the words have the penult fyllable long. Its afpirates are moderate and foft, and no occafion occurs for making the leaft nafal found in pronunciation. This language, notwithftanding its want of the abovementioned confonants, is faid to be very copious, tolerably polifhed, and remarkably expreffive. The Mexican language, like the Hebrew and French, wants the fuperlative term, and like the Hebrew, and fome other living languages of Europe, the comparative term, which are fupplied by certain particles equivalent to thofe which are ufed in other fuch languages. It abounds in diminutives and augmentatives; and alfo in verbal and abftract terms; for there is hardly a verb from which there are not many verbals formed, and fcarcely a fubftantive or adjective from which there are not fome abftracts formed. It is not lefs copious in verbs than in nouns; as from every fingle verb others are derived of different fignifications. The Mexicans, like the Greeks, have the advantage of making compounds of two, three, or four fimple words. The arts of poetry and oratory were much exercifed by the Mexicans. Dramatic, as well as Lyric, poetry was held in high eftimation among thefe people, and they had theatres in which thefe kinds of compofitions were rehearfed. Their mufic was more imperfect than their poetry; and it is faid, that they had no ftringed inftruments. But imperfect as was their mufic, their dances, to which they were much addicted from their youth, were eminently graceful. Their dances, which were of various kinds, were almoft always accompanied with finging, which, like their dances, was always adjufted by pulfatile inftruments. The amufements of the Mexicans were not confined to the theatre and dancing; they had various games, not only for public occafions, but for the relaxation and diverfion of private individuals. The Mexican paintings have been already mentioned; and they were very numerous, and applied to various purpofes. Their colours were brilliant, though their defigns were coarfe and uncouth. We fhall here add to what has been already faid, that the Mexicans were fkilled in fculpture; and the ufual materials of their ftatues were ftone and wood. They alfo valued themfelves on the works which they executed by the casting of metals, and on those Mosaic works which were made of the most delicate and beautiful feathers of birds. The state of medicine among the Mexicans, Clavigero has described much in detail; as he has also their surgery and their baths. Their food and drink consisted of preparations of maize, cacao, chia, and the French bean. Of animal food they partook more sparingly. They had different sorts of wine made of the magnai or Mexican aloe, the palm, and maize. Their dress was simple, consisting of a girdle about the loins, a square mantle, and a piece of square cloth with which the women wrapped themselves from their waists down to the middle of the leg. Besides this they had a little under vest, or waistcoat, without sleeves. Persons of superior station added to their dress a variety of ornaments. Besides feathers and jewels, with which they adorned their clothes, they wore ear-rings, pendants at the under lip, and many at their noses, necklaces, bracelets, and rings like collars round their legs. The ear-rings and pendants of the poor were shells, pieces of crystal, amber, or some other shining little stone; but the rich wore pearls, emeralds, amethysts, and other gems set in gold. Their houshold furniture was mean and coarse. Their beds consisted of two coarse mats of rushes, to which the rich added fine palm mats and shirts of cotton: and the lords, linen woven with feathers. The pillow of the poor was a stone or piece of wood; that of the rich was probably of cotton. Their drinking vessels were made of a fruit similar to gourds. They made no use of candlesticks, or wax, or tallow candles, or of oil to give light. They kindled fire by the friction of two pieces of wood; and generally made use of the achiote, or rocou of the French. It is added, that they also struck fire from flint. After dinner, the lords used to compose themselves to sleep with the smoke of tobacco; the leaves of which they put with the gum of liquid amber, or some other warm odorous herbs, into a little pipe of wood, or reed, or other more valuable substance; they then received the smoke by sucking the pipe and stopping the nostrils with the fingers, so that it might pass more easily to the lungs. The deficiency of soap they supplied by a fruit and a root. As to the population of the whole Mexican empire, Estalla says that it could not have surpassed three or four millions, even including the people of Tlascala, and other towns, not subject to Montezuma.

Having given an extended account of ancient Mexico, we shall now close the article with a brief description of Mexico in its more modern state. The viceroyalty of Mexico may be regarded as the chief in Spanish America, and is extended over a territory equal to an European empire. But there are several inferior governors, named by the Spanish sovereign. A considerable part of his power consists in the patronage of all the churches. His salary was formerly 40,000 ducats, afterwards 60,000, and lastly 84,000, exclusively of the disposal of lucrative offices, monopolies, connivances, presents, &c. which sometimes rise to an enormous amount. His court is formed on the regal model, with horse and foot guards, a grand houshold, and numerous attendants. In their vice-royalty there are three grand tribunals, called Royal Audiences, *viz.* that at Guatemala, that of Mexico, and that of Guadalaxara. There are also several inferior tribunals. The population of all the Spanish provinces in North America has been estimated at little more than seven millions; of whom the natives, called Indians, are supposed to amount to four millions; and the Spaniards and inhabitants of mixed races, are computed at three millions, of which the Spaniards may constitute one-third. It is probable, however, that the whole population of Spanish North America does not exceed six millions. They have suffered much from the small-pox, and a disease called the black vomit, which occasionally ravages like a pestilence. And besides, the number of priests, monks, and nuns is injurious to population. Estalla observes, that though he has not been able to acquire exact information concerning the population of New Spain, yet by the most intelligent computations, there are in the Intendancy of Mexico 1,200,000 souls, including 140,000 for the city: and by the proportion between this province and the others, as well as by the best founded calculations, it may be supposed there are in all the kingdom, three millions and a half of inhabitants. The troops in New Spain are estimated at 43,191, including 5982 regulars, 31,523 militia, &c. and 5686 for garrisons, &c.; so that it may well be doubted whether the whole grand vice-royalty of New Spain could send into the field 15,000 effective men. The revenue which Mexico yields to the Spanish crown has been shewn by Dr. Robertson to amount to above a million sterling, but it is subject to great expences. Dr. Robertson shews, from Campomanes, that the whole produce of the American mines is 7,425,000*l.* of which the king's fifth, if regularly paid, would be 1,485,000*l.*; and it is probable that the mines of New Spain or Mexico, prior to the opulent discoveries in the N.W. provinces, did not yield above one-half of the whole amount. From Estalla we learn, that a very great augmentation has taken place in all the branches of the royal treasury in this vice-royalty; so that the sums paid into the royal treasury have been tripled, and amount annually to 19 millions of dollars, and even more. Allowing the expences of administration, salaries, &c. to amount to 4,800,000 dollars, there will be an overplus of 14,200,000 dollars; that is, more than 1,800,000*l.* sterling. These revenues increase according to the progress of agriculture, the mines, commerce, industry, and population. There are some branches of the revenue which are considerable in their amount; such are the tributes, the products of the coinage, of quicksilver, gunpowder, cards, duties on goods sold, the drink called "pulque," bulls of indulgence, tobacco, lotteries, letters, all which are under the management of the minister of state. Other branches are administered in the royal coffers by their respective superintendants; such as the duties on gold, silver-plate, the assays, tythes, ninths, various ecclesiastic concessions, titles of Castille, vendible offices, compositions and confirmations of land, cock-fighting, snow and ice, stamps, fines, &c. the product of the mines, copper, lead, tin, alum, and others. From this statement there will appear to result a clear sum of 7,800,000 pesos, or about 1,170,000*l.* sterling; and if the peso fuerte be used, one-third must be added.

The ecclesiastical revenue is also very considerable. The archbishopric of Mexico is extremely opulent; and yet deemed inferior to the bishopric of Puebla de los Angelos. The ecclesiastical courts are numerous; and the holy tribunal of the faith, or the Inquisition, is very vigilant and severe. The chapter of the cathedral comprehends 26 ecclesiastics. While the revenue of the archbishop is computed at 100,000 dollars, the dean has more than 10,000; the canons from 7 to 9000, the lesser canons from 2 to 4000; some curacies are worth many thousand ducats; and one in the archbishopric of Mexico is valued at 14,000 ducats a year; while many of the curates, in their career of ambition, become prebendaries and bishops. There are two archbishoprics, those of Mexico and Guatemala, with eight bishops, Puebla de los Angelos, Oaxaca, Durango, Mechoacan, Antequera, Guadalaxara, Yucatan, and Chiapa. The curacies are computed at 235.

The chief city of New Spain is *Mexico*, which see; and there are many other flourishing cities in this wide empire. The

The most interesting in a commercial view are the two chief ports, Acapulco on the Pacific ocean, and Vera Cruz on the Atlantic: to these we may add, Puebla de los Angelos, Cordova, Xalapa, Queretaro, Guadalaxara, and Guatemala, &c. &c. which see respectively.

The manufactures of New Spain are not of any great importance. Coarse cottons form the universal dress of the Indians. There are many tanneries, but the leather is far from being equal to the Spanish; and the same observation is applicable to the glass and earthen ware, though the materials be excellent. The commerce of New Spain is extensive and important, and has recently undergone material improvements; so that since the year 1778, when greater freedom began to be introduced, the commerce has greatly increased. Two advantages have arisen from the liberty of commerce; industrious individuals and the general mass of the people have been enriched; while the great capitals of the former monopolists returned to support agriculture and the mines. The number of shops has been greatly augmented. The imports also have been increased, so that at Vera Cruz alone they amounted, in 1792, to 14,23,000,889 dollars. See VERA CRUZ.

The climate of this country is singularly diversified, between the tropical seasons and rains, and the temperature of the southern and even middle countries of Europe. The maritime districts of Mexico are hot and unhealthy, so as to occasion much perspiration even in January; the inland mountains, on the other hand, present snow and ice in the dog-days. In other inland provinces, however, the climate is mild and benign, with some snow of short duration in winter; but no artificial warmth is necessary, and animals sleep all the year under the open sky. From April to September there are plentiful rains, generally after noon; hail-storms are not unknown: thunder is frequent; and earthquakes and volcanoes occasionally occur. The climate of the capital, in lat. 19° 25′, differs much from that of the parts of Asia and Africa under the same parallel; which difference seems to arise chiefly from the superior height of the ground. Humboldt found, that the vale of Mexico is about 6960 feet above the level of the sea, and that even the inland plains are generally as high as mount Vesuvius, or about 3600 feet. This superior elevation tempers the climate with a greater degree of cold. Upon the whole, the climate cannot be regarded as unhealthy, as the aborigines sometimes attain a great age; and the appearances of decay are not perceived till a late period of life. But though they are exempted from paying tribute after the age of sixty, yet they can rarely count the years of their existence, and they cannot always be traced in the parish registers. It appears from such facts, that the prejudices of some philosophers against the climate and productions of America are unfounded. If there be any where a marked difference in every respect, of climate, men, animals, and vegetables, it is in Africa, a most ancient part of the ancient world, that it must be sought. (See on this subject Clavigero, *ubi supra*.) The face of this interesting country is diversified by grand ridges of mountains, numerous volcanoes, some of which are covered with perpetual snow, cataracts worthy of the pencil of Rosa, delicious vales, fertile plains, picturesque lakes and rivers, romantic cities and villages, an union of the trees and vegetables of Europe and America. The soil is often a deep clay, surprisingly fertile and requiring no manure except irrigation. The progress of agriculture in this country may be partly inferred from the state of the tythes, which, in the archbishopric of Mexico, for ten years, from 1769 to 1779, amounted to 4,132,630 pesos; while, for the ten years from 1779 to 1789, they advanced to 7,820,879 pesos. A similar difference appears in the bishoprics of Puebla, Oaxaca, Guadalaxara, and Durango, which, with Valladolid, comprehend the whole vice-royalty of Mexico; Guatemala being considered as a distinct kingdom. The product of cotton might be increased: of indigo there are annually exported 1500 arobas, and 8000 quintals of pimento: the cultivation of sugar is increased: tobacco has become an important branch: vineyards afford a favourable prospect; and the annual exports of cochineal are computed by Estalla at 23,600 arobas; but by another computation, the quantity of cochineal exported to Spain is 460,000 pounds, costing in New Spain about 12*s. per* pound, and yielding at Cadiz about 13 or 14*s*. The people employed in this culture are estimated at between 25 and 30,000. It has been observed, by the author often cited in this article, that the produce of many articles has been tripled within these few years, such as indigo, cotton, pimento of Talasco, and, above all, the precious cochineal; while tillage, and the rearing of herds and flocks, have been far more universally diffused.

The principal rivers of this country are Rio Bravo, the Medina, Magdalena, or river of Guadalupe, that of Flores, the Arighitas, Chicowansh, Mexicano, Colorado, Gila, Hiaqui, Nasus, Barneja or Esquitlan, Panuco, Zacatula, Yopez, Alvarado, Grijalva, Balleze, Yare, St. Juan, and Chagre. The chief chain of mountains in Spanish North America is Topia or Sierra Madre, to which we may add the grand ridge of Tamalipa, the great chain of Apanaca, Canatagna, and Urraca. The composition of the mountains of New Spain is not accurately ascertained, but it is supposed by Humboldt and Pinkerton to be mostly of argillaceous schistus, which is a substance generally prolific of metals. The volcanoes in New Spain have been reckoned 21 from that of Soconusco in the north to that of Varu in the south. These are all on the south-western coast, and after a considerable interval they again emerge towards the eastern coast, in the vicinity of Mexico. The volcano of Orizava is considered as the most majestic in the viceroyalty. The richest silver mines of New Spain were formerly supposed to be those of Zacatecas, about 200 miles N.W. of Mexico; but at present the grand mines are at Guanajuato, between 21° 30′ and 22° 30′ N. lat. and 103° and 105° W. long., extending from N. to S. 75 miles, from E. to W. 85 miles. Humboldt estimates the population of the administration at 517,300, and of the capital, in N. lat. 21°. W. long. 103°, about 41,000, See GUANAJUATO.

During 11 years from 1766 to 1778, Mr. Pinkerton states, that there were coined at Mexico 203,882,948 pesos, seven reals; but, during another 11 years, from 1779 to 1791, there were coined 252,042,419 pesos, and half a real; the difference being more than 48,000,000. Before the freedom of commerce, the coinage never exceeded 20,000,000 of pesos; and in 1792, 1793, it annually surpassed 24,000,000. In the viceroyalty are found many other metals besides gold and silver. Not far from the capital are mines of tin; this metal is also found in New Mexico. Clavigero says, that the Mexicans used thin pieces of tin and bits of copper for money. Copper is obtained from the rich mines of Guanajuato and also in mines W. of Pasquaro, the capital of Mechoacan. Lead is among the products of New Leon. New Spain also furnishes amber and asphalt, and a few diamonds; the mountains also produce jasper, marble, alabaster, magnet, steatite, jade and talc. The "Tetzontli," red and porous, was used in building, being perhaps, as Pinkerton suggests, a kind of tufa; and the "Itzli," mentioned in a preceding part of this article, as used for mirrors and razors, is called "pietra del Galinazzo" in South America, and is the obsidian or volcanic glass of modern mineralogy. In this country

try have been found, among the fossils, the bones of elephants; bones of this kind were found in digging the foundations of the convent of Guadalupe near Mexico; and they have been found in other places. They are the same with those of the mammoth of Siberia and North America, and belonged to an animal now extinct. Pinkerton's Geography, vol. iii.

Mexico *Proper*, a district or territory of the domain or viceroyalty of Mexico, forming part of the ancient Mexican empire, already amply described in the preceding article.

Mexico, signifying according to Clavigero the place of *Mexitli*, or Huitzilopochtli, *i. e.* the Mars of the Mexicans, on account of the sanctuary there erected to him, the chief city not only of Mexico or New Spain, but of old Spanish America. It is situated, in a beautiful vale, on fenny ground near the banks of the lake of Tezcuco, and crossed by numerous canals, the houses being all founded on piles. Hence it would seem that the waters of the lake have diminished, so as to leave a fenny morass on the west; and it is not improbable that this might happen after the inundation of 1629, when a wide canal was led through a mountain to drain the lake. The scite of the modern Mexico is the same with that of the ancient city; the viceroy residing on the spot of Montezuma's palace, in a large mansion built by Cortes, and still rented at 4000 ducats from the marquises de Valle, his descendants. The ancient city is said to have been situated upon a small island in the forementioned lake; and N. of its junction with that of Chalco, and on the W. side of the lake of Tezcuco, accessible on the W. side by three large causeways of earth and stone, but on the E. side there was no communication otherwise than with canoes or boats. The circumference of the city, exclusive of the suburbs, measured more than 10 miles, and the number of houses was at least 60,000. The city was divided into four quarters, and each quarter into several districts, bearing Indian canoes. The four quarters were divided by four broad roads, which led from the four gates of the area of the greater temple. To the four parts into which the city was divided from the first foundation A.D. 1325, the city of Tlatalolco was added as a fifth, situated towards the N.W. having been united after the conquest of king Axajacatl to Tenochtitlan, and both together formed Mexico. Around the city there were many dykes and reservoirs for collecting water, and within it many canals, so that there was hardly a district that could not be approached by boats. Among the various buildings of the city, besides temples and magnificent royal palaces, there were other palaces in which the feudatory lords resided when they attended the business of the court. All the houses, it is said, those of the poor excepted, had balconies and parapets, and some of them battlements and towers, much smaller than those of the temples; and serving for the defence of the inhabitants in their streets and houses as well as their temples. Besides the large and famous square of Tlateloco, where the principal market was held, there were other smaller markets distributed through the city, where ordinary provisions were sold; and in different places there were fountains and fish-ponds, particularly near the temples, and many gardens, some of which were laid out on the natural level of the earth, and others raised on high terraces. Of the modern city, Chappe d'Auteroche, cited by Pinkerton, gives the following account. The streets are wide and straight, but very dirty: and the houses, resembling those of Spain, are tolerably built. The chief edifice is the viceroy's palace, which stands near the cathedral in a central square, and it is rather solid than elegant. Behind the palace is the mint, in which more than 100 workmen are employed, as the owners of the mines here exchange their bullion for coin. The other chief buildings are the churches, chapels, and convents, which are very numerous and richly ornamented. The outside of the cathedral is unfinished, as they doubt the foundations; but the rail round the high altar is of solid silver, and there is a silver lamp so capacious that three men may go into it to clean it; and it is also enriched with lions' heads, and other ornaments, in pure gold. The images of the Virgin, and other saints, are either solid silver, or covered with gold and precious stones. Besides the great central square, there are two others, each of which has a fountain in the middle. To the N. of the town, near the suburbs, is the public walk, or "Alameda." A rivulet runs round it, and forms a pretty large square, with a bason and jet d'eau in the middle. Eight walks, each of which has two rows of trees, terminate at this bason like a star. There are also some other promenades; although the country about Mexico is swampy ground, and full of canals. Facing the "Alameda" is the "Quemadero," where they burn the Jews, and the unhappy victims of the Inquisition. It is an inclosure between four walls, and filled with ovens, into which are thrown, over the walls, the wretches that are condemned to be burnt alive; condemned, as the author says, by judges professing a religion whose first precept is charity. The Spanish inhabitants are commonly clothed in silk, their hats being adorned with belts of gold and roses of diamonds; for even the slaves have bracelets and necklaces of gold, silver, pearls, and gems. The ladies are of distinguished gallantry.

Mexico, though inland, is a place of immense commerce between Vera Cruz on the E., and Acapulco on the S.; and the shops display a profusion of gold, silver, and jewels. In magnificent regularity it yields to few cities on the ancient continent. Gage says, that, in his time, A.D. 1640, there were supposed to be 15,000 coaches, some of them adorned with gold and gems; the people being so rich, that it was imagined one-half of the families kept carriages. From the work of Estalla, published in 1799, and quoted by Pinkerton, we derive some further information concerning this famous city.

The lake, it is said, has retired a Spanish league from the city, which circumstance is supposed to render the air less salubrious. The winter frost is gentle, and is thought severe when the ice exceeds the thickness of paper. The summer heats are tempered by the regular showers which fall in the evenings. Water-spouts often occur, but they always fall in the lake; however, they have sometimes ruined mining stations. The yearly cold at Mexico, though just within the tropic of Cancer, appears by observations on the thermometer to exceed the heat. The rainy season extends from the middle of May to the middle of September.

The plain of Mexico is, as we have already said, surrounded with mountains, covered with cedars, rare shrubs, and medicinal plants, and containing minerals and precious stones. On these mountains are romantic cottages and farms, watered by clear rivulets. In the middle of this delicious plain are the lakes Tezcuco and Chalco. The city has received no augmentation since the year 1712. The streets are well opened, running in right lines from E. to W. and from N. to S. Great improvements have lately taken place by the cleanliness and good police of the place: the city is lighted, and the streets paved, and sewers and water-courses have been opened, so that Mexico has become the largest, most beautiful, and most sumptuous of the whole Spanish monarchy. The cathedral is a magnificent edifice, the work of 94 years; it has two images of the Virgin, one of gold, which weighs 6984 castellanos, the castellano being the 50th part of a mark, and a mark being $\frac{2}{3}$ds of a pound or eight

eight ounces. For 14 parishes, there are more than 100 other churches, most of which are neat and richly decorated. The religious houses are very numerous, and the nunneries amount to 20. Among the numerous courts and offices of justice, established in this city, are the royal audience and chancery of New Spain; the court for strangers, and those who die intestate; the royal tribunal of registers; the royal coffers; the royal mint; the tribunal of the inquisition; the house of the missions of California; the mount of piety, erected by the charity of the count de Regla, who gave no less than 315,000 pesos; the royal tribunal of mines; that of the descendants of Cortes; the illustrious chapter, justice and government of the noble and imperial city itself, to which the ancient arms were confirmed by Charles V., being a castle with three towers, an eagle on a tree with a snake in its beak, at the foot of the tree is the lake; the whole surmounted with an imperial crown, and supported by two lions. Philip V. granted to Mexico, in 1728, all the privileges and distinctions of a grandee of Spain; and Charles III., in 1773, indulged the chapter, or magistrates, with the use of uniforms laced with gold, declaring their precedence over all tribunals and bodies, except the royal audience and tribunal of accompts. The patroness of the city is St. Mary of Guadalupe, solemnly chosen in 1737, and whose worship has extended over all Spanish America. The general character of the natives, who have a considerable disposition for the arts and boast of their eminent painters, is that of a liberal, courteous, affable, and charitable people. The city has thirteen hospitals, and other charitable establishments. The viceroy is commander in chief, and president of the economical and political government. He resides in the royal palace. He is also president of the tribunal of accompts, which inspects all those of the royal revenue. The city council consists of a corregidor or mayor, twelve regidores, or aldermen, and other officers. The common alcalds judge criminal and civil cases in the first instance subject to an appeal to the royal audience.

The city of Mexico is amply supplied with grain, fruit, and vegetables, from the environs, which are very fertile; those on the east side of the lake of Tezcuco excepted, where vegetation is impeded by the saline exhalations of the lake. The more populous parts of the city extend from north to south four English miles, and from east to west three English miles. The city is surrounded merely by a trench or ditch, without walls or other defence. There are six principal gates; and by the gate of Guadalupe all the pulque enters, which, being the general drink of the inhabitants, yields a revenue of about a million of dollars to the king. The streets are well paved. The manufactory of cigars, employing more than 5000 persons, is a modern and magnificent edifice. The consumption of cigars is very great; for all the Mexican ladies smoke tobacco; and they take their paper cigars from a case of gold or silver, hanging by a chain or ribbon, while on the other side they wear little pincers of the same metal. As soon as one cigar is exhausted, another is lighted: they smoke even at the theatre, and only cease to smoke when they eat or sleep. The tribunal of "La Acordada" was one of the most terrible in the viceroyalty; the judge, who is called captain of the holy brotherhood, being also inspector of prohibited liquors: but Charles III. ordered that the viceroy, with two or three judges, should revise the sentences. The judge of the "Acordada" has from eight to ten thousand men, dispersed through the viceroyalty, under the names of lieutenants, corporals, &c. This holy brotherhood maintains, by its vigilant police, the public tranquillity of the city and viceroyalty, performing their rounds day and night, and speedily punishing every excess. Capital criminals are hanged in a field, called "Exido de Concha," from the name of a captain of this brotherhood; and the tribunal has become more useful, since the viceroy has obtained the privilege of reviewing sentences of death. The market for trifling and second-hand commodities is a square of shops, and the theatre is small but handsome.

Mexico is supplied with water by two aqueducts. The most splendid festivals of the Mexicans are the procession of Corpus Christi, and the entrance of a new viceroy. There are other festivals, such as the anniversary of the conquest, and the publication of the bulls of indulgence.

Although the climate of Mexico is in general salubrious, yet there are some prevalent, and even epidemic diseases. The ravages of the small-pox, however, are likely to be restrained by the Jennerian antidote, which is not unknown even in Mexico; and the black vomit, or yellow fever, is scarcely known in this city. Agues are frequent; pulmonary consumptions, apoplexies and epileptic diseases, spotted fevers and pleurisies, are not uncommon: but the most universal disease of men and women is that called "flado," or the wind, which presents singular and almost incredible symptoms; the patients appearing as if they were demoniac or frantic, sometimes excessively hot and cold by very sudden changes, laughing and weeping, and agitated by convulsions, as if they were possessed. This disease seems to proceed from the hot and unhealthy regimen, and from the abuse of tobacco, destructive alike of the nerves and stomach.

Some individual artizans are very rich, but of late property is more generally diffused: there are, however, many entailed estates, founded by the conquerors, from ten to sixty thousand dollars a-year; but the chief that remain are the products of commerce and of the mines. Within the last twenty or thirty years, the number of houses that sell "pulque" is greatly increased: they are open, by regulation of the police, only from ten in the morning till four in the afternoon, and during this interval they occasion quarrels, and sometimes murders. Estalla computes the population of Mexico at 140,000 souls; but it is probably more considerable. As there is no money of bullion at Mexico, the shop-keepers issue tokens of copper, iron, or wood, which pass in the neighbourhood; and even grains of cacao pass as small coin. The city has several useful regulations for guarding against fires, and any consequent tumults. The water-pipes have been enlarged, and ten public fountains have been constructed, with cocks instead of cisterns, which are found more convenient. The price of bread is regulated every four months, according to the price of grain. The foot-paths are guarded with little pillars; the pavement is kept in good repair, and there is a covered sewer in the middle of the streets, and the city is well lighted by large lamps of the reflecting kind. Watchmen clean and supply the lamps, and guard the houses and passengers; and the municipal troops perform their nightly rounds. In this celebrated capital great quantities of rum are distilled from the refuse of the numerous sugar-mills.

The university of Mexico, founded in 1551, is styled royal and pontifical; and the cloister is composed of two hundred and fifty-one doctors, of all faculties. It is governed by a rector, annually elected by the lesser cloister, composed of the former rector and eight counsellors, chosen by lot from the doctors and bachelors. The office of chancellor is annexed to the dignity of schoolmaster of the metropolis;

tropolis; his office being to preside at conferring some degrees, while on other occasions he holds the second rank. The professors of this university are named by a junta, consisting of the archbishop, the regent of the royal audience, the dean of the cathedral, the oldest inquisitor, the rector of the university, the master of the metropolitan schools, the professor of the first class of theology, and the dean of the faculty. The public library of the university was founded about forty years ago, and is well furnished with old books of divinity, but is miserably deficient in new editions of the classics, or new works of science and philosophy. This library is open to the public at certain hours, except on Sundays and holidays. The college of St. Mary-of-all-Saints is the only one of the first rank in the Spanish American possessions: it has a public library. The seminary was founded by an archbishop of Mexico in 1682; and at present it has thirteen professors. The students amount to four hundred, and a new building was erected in 1750. The Jesuits had formerly five colleges, two of which only remain: they are directed by the viceroy, or a junta, of which he is president. The buildings are magnificent; the chapel and grand hall being the most beautiful in the vice-royalty. The college of St. John of Lateran is the most ancient of any in New Spain, having been founded in the reign of Charles V., for the instruction of those descended from Spanish and Indian parents. It has been improved in 1764, and again in 1789. The college of St. Jago is without the walls of Mexico, in a house of the Franciscans; but it is now merely a boarding-school for children. Other religious orders have also public schools. A college of mines has lately been erected, in which young persons are not only instructed in that science, but in other important parts of education. The royal academy of the three noble arts is a valuable institution: it is provided with good professors in architecture, painting, sculpture, and engraving; and there is also a professor of mathematics. There are also particular houses in Mexico where Latin grammar is taught by preceptors approved by the government and university.

The environs of Mexico are richly cultivated with flax, hemp, cotton, tobacco, indigo, sugar, and magneys; and furnish the city with ample supplies of meat, poultry, vegetables, and fruits. The most celebrated sanctuary in the vicinity of the city is that of our lady of Guadalupe, which has a college, a church, &c. Another sanctuary, or house of pilgrimage, is that of our lady de los Remedios, erected on the spot whither Cortes retired when he was repulsed from Mexico. Without the barrier of Santiago is the sanctuary of our lady of the Angels, formerly the residence of a hermit. At the distance of five leagues from Mexico is the desert of the Carmelites, in an enclosure about a league in circuit; the retreat of the most austere monks there being in solitary cells. The aqueduct of Chapultepec adorns the immediate environs; and on the hill so called was a palace of Montezuma. Traspana is another place of resort, where are several good houses; and many settle there, as the air is esteemed very healthy. On the side of San Lazaro, about half a league from Mexico, is the rock of the baths, which are warm, but the quality is not ascertained. N. lat. 19° 54′. W. long. 99° 51′. Pinkerton's Geog. vol. iii.

Mexico, *New*, a large territory of the Spanish dominions in North America, sometimes called a kingdom, but properly a single province, lying eastward of California, and divided by the gulf from that peninsula. Northwards it is bounded by high mountains and an unknown country, on the east by Louisiana, on the west by the Californian lake and Rio Colorado, and on the south by some of the provinces of New Spain, or Mexico proper. This province was discovered by a missionary in 1581, but scarcely subdued till 1644; nor were many missions established till after the year 1660; and the capital, Santa Fé, was founded in 1682. It is a fertile and delightful province, producing maize, wheat, and excellent fruits. The mines are said to be all of tin; and the animals and plants are of singular variety. In the map of Alzate, the northern limit is marked at 38°, and the southern at 30° 30′; the medial breadth, on both sides of the Rio Bravo, being only 2°, or 120 geographical miles. Pinkerton.

Mexico, a town of America, in Oneida county, New York, at midway between Oneida lake and Oswego, 20 miles from each. The township is extensive, comprehending a number of houses.

Mexico, *Gulf of*, a large bay or gulf of the Atlantic, extending north to south, from the coast of Florida to the coast of Tabasco and Yucatan, about 600 miles, and east to west, from Cuba to the coast of Mexico, about 700. This gulf lies in a favourable climate, and presents at its entrance the grand archipelago of North American islands, called the West Indies. See Gulf *Stream*.

MEXIMIEUX, a town of France, in the department of the Ain, and chief place of a canton, in the district of Trevoux; 17 miles N.E. of Lyons. The place contains 1691, and the canton 8372 inhabitants, on a territory of 230 kiliometres, in 14 communes.

MEYAPONTE, a river of Brasil, which runs into the Parana.

MEYENBERG, a town of Switzerland, in the Free Bailiwicks, once an independent lordship; 10 miles N. of Lucerne.

MEYENBURG, a town of Brandenburgh, in the mark of Pregnitz; 60 miles N.N.W. of Berlin. N. lat. 53° 18′. E. long. 12° 15′.

MEYENFELD, a town of the Grisons, and principal place of a jurisdiction. It is said to have been the first place in which the reformation was encouraged. This town was a kind of staple for goods that passed to and from Germany and Italy; 52 miles E. of Lucerne. N. lat. 46° 57′. E. long. 9° 38′.

MEYER, James, in *Biography*, an historian, was born in Flanders in the year 1491. He studied in the university of Paris, and entered into holy orders. For several years he taught school at Ypres and Bruges, and in the latter city had a benefice, in the church of St. Donatian. He died at Blankenberg, in the year 1552. He was on terms of intimacy with Erasmus, and other learned men; and wrote several works, of which the principal are, 1. "Flandricarum Rerum Decus," being an account of the origin, antiquity, nobility, and genealogy, of the counts of Flanders; and, 2. "Annales Rerum Flandricarum," which begin with the year 445, and come down to 1477. They are written in a pure and easy style, and have been reprinted in the collection of Belgic historians. Moreri.

MEYERA, in *Botany*, a genus of Schreber's, named, we presume, in honour of Dr. Frederic Albert Anthony Meyer, a physician at Göttingen who died in 1795, and who was the author of various tracts on Natural History. Willdenow has not adopted the genus, nor do we find any notice of it under *Sclerocarpus*, although its author says they are nearly allied, but belonging to different orders of the class *Syngenesia*. It must however be recollected that these orders are not always permanently distinct in nature. *Meyera* rests solely on the authority of Schreber, not having been taken up by any other author, so that we can only translate

translate his own generic character. If its habitat had been published, possibly a more clear and satisfactory reference might have been made of the plant in question. Schreb. 570.—Class and order, *Syngenesia Polygamia Superflua.* Nat. Ord. *Discoideæ*, Linn. *Corymbiferæ*, Juss.

Gen. Ch. *Common Calyx* of four, large, broad, heart-shaped, concave, veined leaves, spreading at the top, rather acute, shorter than the disk, the two inner ones opposite. *Cor.* compound, tubular, convex; florets in the disk numerous, perfect, funnel-shaped, five-cleft, somewhat erect; those of the radius several, ligulate, lanceolate, entire. *Stam.* (in the perfect florets) Filaments five, capillary; anthers cylindrical, tubular, five-toothed. *Pist.* (in the same) Germen oblong; style thread-shaped, longer than the stamens; stigmas two, revolute. In the female ones the style is longer than the florets. *Peric.* none, except the permanent calyx. *Seed* in both kinds of florets solitary, oblong, transversely compressed, crescent-shaped, striated, scaly; down none. *Recept.* convex, small; scales cartilaginous, imbricated, triangular, incurved, furrowed at the back, downy towards the top externally, oblique at the extremity, each enveloping a single seed, the outer ones a little broader.

MEYNIAC, in *Geography*, a town of France, in the department of the Correze, and chief place of a canton, in the district of Ussel. The place contains 2978, and the canton 7726 inhabitants, on a territory of 322½ kiliometres, in 11 communes.

MEYNTHAL, or VAL DI MAGGIA. See MAGGIA.

MEYO, in *Commerce*, a measure for corn, salt, and other dry commodities, in Portugal; it contains 15 fanegas; each fanega being = 4 alquieres = 8 meyos = 16 quartos = 32 outavas = 64 mequias. The alquiere is = 675 French = 817 English cubic inches; so that 21 alquieres = 1 English quarter, nearly, or, more exactly, 50 alquieres = 19 English bushels. In the common course of business 4 alquieres of Oporto are reckoned equal to 5 alquieres of Lisbon, and 2 alquieres of Oporto, or 2½ of Lisbon, are computed to be equal to an English bushel.

MEYRINGEN, in *Geography*, a large and neat village of Switzerland, the capital burgh of Hasliland, a district in the canton of Berne, which enjoys peculiar privileges. The people are governed by their own magistrates, and only take oaths of fidelity to the sovereign council. The authority, which the bailiffs in the other cantons enjoy, is possessed in a great measure by the landamman, who resides at Meyringen. The place is situated near the Aar, in a romantic vale, surrounded by meadows of a luxuriant verdure, and sprinkled with cottages, which are occasionally separated by huge stones and deep channels, the vestiges of storms and floods; 28 miles S.E. of Thun.

MEYRUEIS, a town of France, in the department of the Lozere, and chief place of a canton, in the district of Florac; 22 miles S. of Mende. The place contains 2890, and the canton 5235 inhabitants, on a territory of 345 kiliometres, in seven communes. N. lat. 44° 11'. E. long. 3° 31'.

MEYSSAC, a town of France, in the department of the Correze, and chief place of a canton, in the district of Brives. The place contains 2072, and the canton 10,466 inhabitants, on a territory of 160 kiliometres, in 14 communes.

MEYWAR. See OUDIPOUR.

MEYZIEU, a town of France, in the department of the Isere, and chief place of a canton, in the district of Vienne. The place contains 1045, and the canton 9547 inhabitants, on a territory of 212½ kiliometres, in 16 communes.

MEZA, a river of Russia, in the government of Polotsk, which runs into the Dwina; 16 miles N.E. of Veliz.

MEZAIR. See MES-AIR.

MEZALANA, in *Geography*, a town of Italy, in the department of the Mincio; four miles S. of Mantua.

MEZANA, a town of Liamone, in the island of Corsica, and chief place of a canton, in the district of Ajaccio: the canton contains 1751 inhabitants.—Also, a town of Italy; five miles S. of Padua.

MEZANA, *La*, a town of Naples, in Basilicata; 17 miles S.S.W. of Tursi.

MEZANINE, or MEZZANINE, a term used by some architects, to signify an attic, or little story, contrived occasionally over the first story, for the conveniency of a wardrobe, or the like.

The word is borrowed from the Italians, who call *mezzanini* those little windows, less in height than breadth, which serve to illuminate an attic, or entresole.

MEZDA, in *Geography*, a town of Africa; 60 miles S. of Tripoli.

MEZDAGA, a town of Fez, in the province of Chaus, at the foot of mount Atlas.

MEZE, a town of France, in the department of the Herault, and chief place of a canton, in the district of Montpellier; 15 miles S.W. of Montpellier. The place contains 2800, and the canton 8729 inhabitants, on a territory of 135 kiliometres, in seven communes. N. lat. 43° 25'. E. long. 3° 42'.

MEZELIEMEINA, a town of Africa, in Tunis, on the lake Bizerta; 28 miles N. of Tunis.

MEZEMNA, a sea-port of Algiers, in the kingdom of Fez, on the coast of the Mediterranean; 80 miles E. of Tetuan. N. lat. 35° 22'. W. long. 4° 5'.

MEZEN, a sea-port town of Russia, in the government of Archangel, near the White sea, at the mouth of a river of the same name; 128 miles N.N.E. of Archangel. N. lat. 66° 30'. E. long. 43° 34'. The river rises in the government of Archangel, N. lat. 64° 15'. E. long. 49° 14', and runs in a S.W. direction to the town of Poslanskoi, when, changing its course, it runs N. westerly to N. lat. 66° 30'. E. long. 48° 34', where it flows into the Frozen ocean.

MEZEN, a mountain of France, which gives name to a district, in the department of the Ardéche; 27 miles W. of Valence.

MEZERAI, FRANCIS EUDES DE, in *Biography*, a celebrated French historian, was born in 1610, at Ry, in Lower Normandy. After studying at Caen he came to Paris, and obtained the post of an officer of the artillery, in which capacity he served two campaigns. He then quitted the army, and retired to the college of St. Barbe, where he applied with great ardour to study, having projected a history of France, of which, under the patronage of cardinal Richelieu, he published the first volume, folio, in the year 1643. The two others appeared in 1646 and 1651. On account of this, the court recompensed his labours by a pension of 4000 livres, with the title of historiographer. This success engaged him to compose an abridgment of it under the title of "Abregè Chronologique de l'Histoire de France," in three vols. 4to.; it was reprinted in Holland, in 6 vols. 12mo. In this work he published an account of the origin of all the public imposts, with some very free reflections, which gave so much offence to the minister Colbert, that he remonstrated with the author, who promised

mised to make the requisite corrections in the second edition. This he performed, but, at the same time, informed the readers that he was compelled to do so; and his corrections, moreover, were only palliations, he was therefore punished by withdrawing half his pension. On his making a complaint, the other half was also suppressed, upon which he declared, that he would not continue his history. On the death of Conrart, in 1675, he was elected to the vacant place of perpetual secretary to the French academy; in this situation he prepared a sketch of the projected dictionary of the academy. Mezerai died in 1683. Besides the works already mentioned, he wrote "Traité de l'Origine des François;" "L'Histoire des Turcs, depuis 1612 jusqu'en 1649." A translation of John of Salisbury, "De Nugis Curialium," and of Grotius, "De veritate Relig. Christ." Mezerai was a man of great singularities in his temper and habits. He was fond of low company, and so squalid in his dress, that he was once taken up by the police for a beggar. He never wrote but by candle-light, even in the day-time, and in the midst of the summer, and he had always a bottle on the table. He affected to be a sceptic in his religion, but in his last illness his early impressions recurred, and he entreated his friends to forget his impieties, and to recollect "that Mezerai dying was more to be believed than Mezerai in health." Moreri.

MEZEREON, in *Botany*, seems by Bauhin's *Pinax* 462, and Lobel's *Adversaria* 157, to be a word of Arabian origin. In the book last mentioned it is said to belong properly to the *Cneorum tricoccum* of Linnæus, which however is not known to grow in Arabia, but in Spain and the south of France. The name is now transferred to the *Daphne Mezereon*, or *Laureola Mezereon Germanica* of the older writers, and is become the familiar English appellation of that charming shrub. See Cneorum and Daphne.

MEZIDON, in *Geography*, a town of France, in the department of the Calvados, and chief place of a canton, in the district of Lisieux; 11 miles W.S.W. of Lisieux. The place contains 528, and the canton 9089 inhabitants, on a territory of 160 kiliometres, in 34 communes.

MEZIERES, a town of France, and principal place of a district, in the department of the Ardennes, situated on an island formed by the Meuse, over which it has two bridges, with a citadel; two miles S. of Charleville. The place contains 7400, and the canton 11,567 inhabitants, on a territory of $137\frac{1}{2}$ kiliometres, in 12 communes. N. lat. 49° 46'. E. long. 4° 47'.—Also, a town of France, in the department of the Indre, and chief place of a canton, in the district of Le Blanc. The place contains 1338, and the canton 7084 inhabitants, on a territory of 390 kiliometres, in nine communes.—Also, a town of France, in the department of the Upper Vienne, and chief place of a canton, in the district of Bellac. The place contains 1313, and the canton 9107 inhabitants, on a territory of $307\frac{1}{2}$ kiliometres, in eight communes.

MEZIN, a town of France, in the department of the Lot and Garonne, and chief place of a canton, in the district of Nerac; six miles S.S.W. of Nerac. The place contains 2860, and the canton 10,136 inhabitants, on a territory of 280 kiliometres, in 16 communes. N. lat. 44 3'. E. long. 0° 20'.

MEZIRIAC, Claude-Gaspard Bachet, in *Biography*, was born in 1581, of a noble family at Bourg-en-Bresse. He entered among the Jesuits, and at the age of twenty was professor of rhetoric at their house in Milan. A bad state of health induced him to quit the society, and he passed much of his time at Paris and Rome in literary pursuits. His reputation was so great, that he was mentioned as a fit person to be preceptor to Lewis XIII., but the dread of such an office induced him to quit Paris and retire to his native place. He died in 1638, leaving behind him many works that bore witness to his great erudition. He wrote verses in French, Latin, and Italian, and was a profound Greek scholar, an excellent grammarian and critic, a philosopher, theologian, and mathematician. His principal works are as follow: "Problemes plaisans et delectables que se font par les Nombres:" "Diophanti Alexandrini Arithmeticorum Lib. vi. et de Numeris multangulis Lib. i." translated from the Greek with commentaries: "La Vie d'Esope;" "Epistolæ et Poemata varia."

MEZOUR, in *Geography*, a town of Asia, in Candahar; 63 miles N.E. of Candahar.

MEZTITLAN, a town of Mexico; 25 miles N. of Mexico.

MEZUZOTH, in the *Jewish Customs*, certain pieces of parchment, which the Jews fix to the door-posts of their houses, taking that literally which Moses commands them, saying, "Thou shalt never forget the laws of thy God, but thou shalt write them upon the posts of thy house, and on thy gates." This expression means nothing else, but that thou shalt always remember them, whether thou comest into thy house, or goest out. But the Hebrew doctors imagined, that the law-giver meant something more than this. They pretended that, to avoid making themselves ridiculous, by writing the commandments of God without their doors, or rather to avoid exposing themselves to the profanation of the wicked, they ought, at least, to write them on a parchment, and to enclose it in something. Therefore they wrote these words upon a square piece of parchment, prepared on purpose with a particular ink, and a square kind of character. (Deut. vi. 4, 5, 6, 7, 8, 9.) "Hear O Israel the Lord our God is one Lord, &c." Then they left a little space, and afterwards went on, (Deut. xi. 13.) "And it shall come to pass, if thou shalt hearken diligently to my commandments, &c.," as far as, "Thou shalt write them upon the door-posts of thy house, &c." After this they rolled up the parchment, and put it into a case of reeds, or other matter; they wrote on the end of the case the word "Shadai," which is one of the names of God; and they put it at the doors of their houses, chambers, and all places most frequented; they fixed it to the knockers of the door, on the right side; and as often as they entered in, or went out, they touched it in this place with the end of their finger, which they afterwards kissed out of devotion. The Hebrew word *mezuza* properly signifies the door-posts of a house; but it is also given to this roll of parchment now mentioned. Leo of Modena may be here consulted.

MEZZA Pausa, in the *Italian Music*, *half a pause*, intimates that the part wherein it is found must be still the time of a semibreve in common time. See Pause.

Mezza *Tirata*. See Tirata.

MEZZAROLA, in *Commerce*, a liquid measure of Genoa, containing for wine two barrili, or 100 pinte, and reckoned at 18 rubbi, or 450lbs. peso sottile; the mezzarola is = about 39 English gallons.

MEZZEREB, in *Geography*, an island in the Red sea. N. lat. 27° 43'.

MEZZO, an Italian adjective, which means half; as *mezzo forte*, *mezzo piano*, *mezza voce*, which imply nearly the same thing, *i. e.* a middle degree of piano, or soft. *Mezzo soprano*, a pitch of voice between the *soprano* or treble, and counter-tenor. See Clefs, and Compass *of Voices*.

MEZZO-

MEZZO-TINTO, in *Sculpture*, a particular manner of engraving figures on copper.

Mezzo-tinto is said to have been first invented by prince Rupert, about the year 1649; and Mr. Evelyn, in his History of Chalcography, gives us a head, performed by that prince, in his way: though Mr. Le Blon is said to have introduced it into practice with the greatest success.

The prince laid his grounds on the plate with a channelled roller; but one Sherwin, about the same time, laid his ground with a half-round file, which was pressed down with a heavy piece of lead. Both these grounding tools have been laid aside for many years; and a hand-tool, resembling a shoemaker's cutting-board-knife, with a fine crenelling on the edge, was introduced by one Edial, a smith by trade, who afterwards became a mezzo-tinto painter.

It is very different from the common way of engraving. To perform it, they rake, hatch, or punch the surface of the plate all over with a knife, or instrument made for the purpose, first one way, then the other, across, &c., till the face of the plate be thus entirely furrowed with lines or furrows, close and as it were contiguous to each other; so that if an impression was thus taken from it, it would be one uniform blot, or smut.

This done, the design is drawn, or marked on the same face; after which, they proceed with burnishers, scrapers, &c. to expunge or take out the dents or furrows, in all the parts where the lights of the piece are to be; and that more or less, as the lights are to be stronger or fainter: leaving those parts black, which are to represent the shadows, or deepenings of the draught.

As it is much easier to scrape or burnish away parts of a dark ground, corresponding with the outline of any design sketched upon it, than to form shades upon a light ground, by an infinite number of hatches, strokes, and points, which must all terminate with exactness on the outline, as well as differ in their force and manner, the method of scraping, as it is called in mezzo-tinto, consequently becomes much more easy and expeditious, than any other method of engraving. The instruments used in this kind of engravings are cradles, scrapers, and burnishers.

In this engraving, the plate must be prepared and polished in the same manner as for other engraving (see Copper-*plates*); and afterwards divided equally by lines, parallel to each other, and traced out with very soft chalk. The distance of these lines should be about one-third of the length of the face of the cradle which is to be used, and these lines should be marked with capital letters, or strokes of the chalk. The cradle is then to be placed exactly betwixt the two first lines, and passed forwards in the same direction; being kept as steady as possible, and pressed upon with a moderate force. The same operation must be repeated with respect to all the other lines; till the instrument has thus passed over the whole surface of the plate. Other lines must be drawn then from the extremities of the other two sides, in the same manner; which intersecting the first at right angles, will with them form squares; and the same operation must be repeated with the cradle, as in the case of the first. New lines must then be drawn diagonally, and the cradle passed betwixt them as before; and when the first diagonal operation is performed, the lines must be crossed at right angles as the former, and the cradles passed betwixt them in the same manner. The plate having undergone the action of the cradle, according to the disposition of the first order of lines, a second set must be formed, having the same distances from each other as the first. But they must be so placed as to divide those already made into spaces one-third less than the whole extent; *i. e.* every one after the first on each side will take in one-third of that before it, *e. g.* beginning at A, of which the first third must be left out; the third of B will consequently be taken in; and so of the rest. These lines of the second order must be marked with small letters, or lesser strokes, to distinguish them from the first; and the same treatment of the plate must be pursued, with respect to them, as was practised from the others. When this second operation is finished, a third order of lines must be made, the first of which, *e. g.* in A, must omit two-thirds of it, and consequently take in two-thirds of B, &c. By these means the original spaces will be exactly divided into equal thirds; and the cradle must be again employed betwixt these lines as before. When the whole of this operation is finished, it is called *one turn;* but in order to produce a very dark and uniform ground, the plate must undergo the repetition of all these several operations, for above twenty times; beginning to pass the cradle again betwixt the first lines, and proceeding in the same manner through all the rest. When the plate is prepared with a proper ground, the sketch must be calked on it, by rubbing the paper on the backside with chalk. It is also proper to overtrace it afterwards with black-lead or Indian ink. The scraping is then performed, by parting or cutting away the grain of the ground in various degrees; so that none of it is left in the original state, except in the touches of the strongest shade. The general manner of proceeding is the same as drawing with white upon black paper. The masses of light are first begun with; and those parts, which go off into light in their upper part, but are brown below: the reflections are then entered upon; after which the plate is blackened with a printer's blacking-ball made of felt, in order to discover the effect; and then the work is proceeded with; observing always to begin every part in the places where the strongest lights are to be.

But the present mode of this engraving is rendered still more expeditious and easy to the artist, not only in laying the ground, but in scraping the plate. Instead of using the cradle or grounding tool three times, it is now found to produce a better grain by only repeating it twice, or *double ways*, as it is called by artists. In laying the ground, the copper is ruled as formerly, and instead of taking up a third of the way already executed, it now only takes up one-half, by which means the grain of the ground, or texture, is more dotty, and has a more solid look, and consequently is less liable to the appearance of cuts or lines, which was too much the character of the former process. Fifteen ways in this manner worked close, will be sufficient to fill the ground, and give it a velvet-like tint. The former mode of making an outline from the painting, is now found to be wholly unnecessary, and the most ready and masterly method is to square the painting in any number of given squares, and the same number on the plate, agreeable to the size of it, and with a black-lead pencil draw backwards the picture (which with a little practice becomes familiar) on the ground, and the scraping is then performed by the original method. The art of mezzo-tinto engraving was considered formerly as only adapted to broad subjects, and where high minute finishing was required, it was thought vain to attempt it; but the great advances made in that art since the time of prince Rupert, have convinced every amateur to the contrary, and the successful works of Eadom, especially his masterly flower-pieces, are admirable specimens of its power, as also the ever grateful productions of Hodges, Dixon, and many rising artists of the present time. In engraving portraits, it is decidedly most appropriate for resembling both the touch and effect. This is the most usual way of performing this operation.

The art of scraping mezzo-tintos has been applied to the printing with a variety of colours, in order to produce the resemblance of paintings. The inventor of the method of doing this was J. C. Le Blon, a native of Francfort, and pupil of Carlo Marata, between the years 1720 and 1730. It was established by the inventor on this principle, that there are three primitive colours, of which all the rest may be composed, by mixing them in various proportions: that any two of these colours being mixed together, preserve their original power, and only produce a third colour, such as their compound must necessarily give; but if transparent colours be mixed, and three primitive kinds compounded together, they destroy each other, and produce black, or a tendency to it, in proportion to the equality or inequality of the mixture; and that, if, therefore, these three colours be laid, either separately, or upon each other, by three plates, engraved correspondently, on these principles, to the colouring of the design, the whole variety of teints necessary may be produced. The requisites, therefore, to the execution of any design in this method of printing, are as follow. 1. To settle a plan of the colouring to be imitated; shewing where the presence of each of the three simple colours is necessary, either in its pure state, or combined with some other, to produce the effect required; and to reduce this plan to a painted sketch of each, in which not only the proper outlines, but the degree of strength should be expressed. 2. To engrave three plates according to this plan, which may print each of the colours exactly, in the places where, and proportion in which, they are wanted. 3. To find three transparent substances, proper for printing with these three primitive colours. The manner in which Mr. Le Blon prepared the plates was as follows: the three plates of copper were first well fitted with respect to size and figure to each other, and grounded in the same manner as those designed for mezzo-tinto prints: and the exact place and boundary of each of the three primitive colours, conformably to the design, were sketched out on three papers, answering in dimensions to the plate. These sketches were then calked on the plates; and all the parts of each plate, that were not to convey the colour, to which it was appropriated, to the print, were entirely scraped away, as in forming the light of mezzo-tinto prints. The parts that were to convey the colour were then worked upon; and where the most light or diluted teints of the colour were to be, the grain in the ground was proportionably taken off; but where the full colour was required, it was left entire. In this regard was had, not only to the effects of the colour in its simple state, but to its combined operation, either in producing orange-colour, green, or purple, by its admixture with one alone; and likewise to its forming brown grey, and shade of different degree; by its co-operation with both the others. But though the greatest part of the engraving was performed in the mezzo-tinto manner, yet the graver was employed occasionally for strengthening the shades; and for correcting the outline, where it required great accuracy and steadiness. It was found necessary sometimes to have two separate plates for printing the same colour, in order to produce a stronger effect: but the second plate, which was used to print upon the first, was intended only to glaze and soften the colours in particular parts that might require it. With respect to the black and brown teints, which could not be so conveniently produced in a due degree, by the mixture of the colours, umber and black were likewise used.

With respect to the order in which the plates are to be applied, it may be proper to observe, that the colour which is least apparent in the picture should be laid on first; that which is betwixt the most and least apparent, next; and that which predominates, last; except where there may be occasion for two plates, for the same colour, as was before mentioned; or where there is any required for adding browns and shades.

Mr. Le Blon applied this art to portraits, and shewed, by the specimens he produced, the possibility of its being brought, by farther improvements, to afford imitations of painting, which might have some value. It is nevertheless much better adapted to the simpler subjects, where there are fewer intermixtures of colours; and where the accuracy of the reflections, and demi-teints are not so essentially necessary to the truth of the design, from the greater latitude of form, and disposition of the colour, as in plants, anatomical figures, and some subjects of architecture. But perhaps plates engraved, or rather finished, with the tool, particularly with respect to the outline, would be better accommodated in some of these cases, than those prepared only by scraping.

Mr. Cochin remarks, at the end of an account he has given of Mr. Le Blon's manner, that though this ingenious artist confined this method principally to the use of three colours; yet should this invention be again taken up and cultivated, there would be more probability of success in using a greater variety: and that several different kinds might be printed by one plate; provided they were laid on in their respectively proper places, by printing balls, which should be used for that colour only. His hint might, however, be very greatly improved, by the further assistance of pencils, accommodated to the plates, for laying on the colours in the proper parts.—Handmaid to the Arts, vol. ii. p. 182, &c. Encyclopedie, Art. GRAVEUR *en Couleurs*, &c.

For the method of taking off mezzo-tinto prints in glass, see BACK-*painting*.

MEZZOVO, in *Geography*, a ridge of mountains in European Turkey, which divides Thessaly from Albania.

MGLIN, a town of Russia, in the government of Novgorod Sieverskoi, on the Iput. N. lat. 53° 12′. E. long. 32° 34′.

MHARAS, a mountain of Arabia, in the province of Yemen; 16 miles W. of Kataba.

MI, a river of China, which rises in the province of Chantong, and runs into the Chinese sea, N. lat. 37° 12′. E. long. 129° 14′.

MI, in *Music*, the third sound in the ascending scale of Guido's hexachords. See SOLMISATION, and HEXACHORD.

MIA, in *Geography*, a town of Japan, in the island of Niphon; 85 miles E. of Meaco.

MIACO. See MEACO.

MIADWZNA, a town of Poland, in the palatinate of Kiev; 36 miles S.S.E. of Bialacerkiev.

MIALNANAEN, a mountain of Scotland, in the county of Perth; 10 miles E.N.E. of George's Town.

MIAM, in *Commerce*, a weight for gold at Malacca, 320 miams being = 20 buncalls = a catty = 29oz. 17dwt. 16gr. English troy; and a money of account at Siam, 16 miams being = 4 ticals = a tale, and 20 tales = a catty; and as 10 miams are accounted = 1 Chinese tale, 5 tales of Siam = 8 Chinese tales.

MIAMAJA, in *Geography*, a town of Japan, on the N. coast of Niphon. N. lat. 41° 10′. E. long. 141°.

MIAMI, or MAWMEE, *Great*, a river of America, in the state of Ohio, forming the western boundary of the state, and dividing it from Indiana territory. It enters the Ohio, 333 miles below Marietta, according to the winding of the river. At its mouth it is 300 yards wide; but at the Pickawee towns, above 70 miles higher, it is not above 30 yards wide, though it is passable for loaded boats 50 miles higher. Its stream is rapid, without cataracts. This river has several boatable branches, one of which extends towards the Sandusky, with an an intermediate portage of six or eight miles, and another opens a communication with Au Glaze by a short portage. The channel of the river is stony; hence it is sometimes called Assereniet, or Rocky river. Its waters are very clear and transparent. One of the principal branches of the Miami river is called "Mad river," or "Pickawee fork." This is a pleasant stream, and passes through an agreeable level country of the greatest fertility.

MIAMI, *Little*, discharges itself, after a south-western course, into the Ohio, about 300 miles below Marietta. It is 70 miles in length, and at its mouth 70 miles wide. Its depth of water does not allow the passage of loaded boats. On its borders the land is good, and its banks are so high that it is seldom overflowed.

MIAMI *of the Lake*, sometimes called "Omee" and "Manmick," is a considerable stream, navigable with canoes to the portages which lead to the head of the Wabash, and through Au Glaze, one of its branches towards the head of Loromie's creek, a head water of the Great Miami. Its portage is three miles. This river falls into lake Erie, at the S.W. corner of the lake. On this river there is a village called Miami, near Miami fort.

MIAMIS, an Indian nation, which inhabit the vicinity of the Miami river, and the southern side of lake Michigan. These people can raise about 300 warriors. In consequence of lands ceded to the United States by the treaty of Greenville, Aug. 3d, 1795, government paid them a sum in hand, and engaged to pay them annually, for ever, to the value of 1000 dollars in goods.

MIANA, a town of Persia, in the province of Adirbeitzan, where M. Thevenot the traveller died on his return from Ispahan; 45 miles S. of Ardebil. N. lat. 37° 12'. E. long. 47° 22'.—Also, a town of Italy, in the Bellunese; 24 miles W.N.W. of Belluno.

MIAO-TSE' MOUNTAINEERS, a general name under which are comprehended several tribes, who differ from one another only by some particular customs. This half-barbarous people are dispersed throughout the Chinese provinces of Se-tchuen, Koei-tcheou, Hou-quang, Quang-si, and on the frontiers of the province of Quang-tong. They often come down from their mountains, and make incursions into the flat, open country, although the Chinese, in order to restrain them, have built castles and fortresses in several places, in which numerous garrisons are maintained. The Miao-tsé are under the government of princes, who have no less authority over their subjects than those of the "Lo-los" have over theirs; they maintain houshold officers and a regular militia; they have under them several petty feudatory lords, who, although sovereigns, are obliged to levy troops for them whenever they receive orders. The usual arms of the Miao-tsé are bows and half-pikes. Their horses are much esteemed by the Chinese, on account of the agility with which they climb the mountains. The Miao-tsé, who inhabit the province of Koei-tcheou towards Liping-fou, have houses built of brick, containing only one story; in the lower part of which they keep their horses, oxen, cows, sheep, and hogs, which render their habitations very filthy and disgusting; and therefore the Tartar princes prefer lodging in the wretched barracks of the soldiers than in these houses. These Miao-tsé are collected in villages, and live in great harmony with one another. They cultivate the earth, make cloth, and manufacture a kind of carpets, which serve to cover them during the night. Their cloth is only a coarse sort of muslin of little value; but their carpets are good, and well woven. The timber of their forests is purchased by the Chinese, and floated down the river that traverses their country; and the price consists of a certain number of cows, oxen, and buffaloes. The skins of these animals are used by the Miao-tsé for breast plates, which they cover with thin lamina of steel or copper. The ordinary dress of these Miao-tsé consists of a pair of drawers, and a kind of jacket which laps over their breast. Those of the Miao-tsé tribe, who are dispersed in that part of Hou-quang which is nearest to the provinces of Quang-tong and Quang-si, are equally independent, though they seem to acknowledge the jurisdiction of the Chinese mandarins. They climb their rocks and run among their mountains barefooted, with great speed. The head-dress of their women is singular, as they place transversely upon their heads a board about a foot long, and five or six inches broad, over which they spread their hair, fixing it to the wood by means of wax. The greater part of the Miao-tsé is composed of independent people; but some of them are subject to the Chinese government. Such are those who live towards the middle, and southern part of the province of Koei-tcheou, and who are under two distinct governments. Some of these are subject to the mandarins of the province, and form a part of the Chinese people, whose customs they have adopted. The rest are subject to hereditary mandarins, who are considered as naturalized, although Chinese by extraction. These petty princes judge, in the first instance, the causes of their vassals, and have a right of punishing them, but not capitally. The Chinese entertain a sovereign contempt for the whole Miao-tsé nation. Their account of them is very unfavourable; but the missionaries assure us, that they found them an active, laborious, and obliging people, and remarkably honest and punctual in restoring the baggage, and other effects which they had entrusted to their care. These mountaineers, on their part, no less detest the Chinese, whom they consider as harsh and severe masters, who, unable to subdue them, and reduce them to a state of slavery, keep them blocked up in their country, and cut off from all communication with their neighbours. In the year 1776 these mountaineers were driven into their inmost retreats, and totally subdued by Akoui, a Chinese general. Grosier's China, vol. i.

MIASMA (from μιαίνω, the most direct interpretation of which is *to daub*) may be applied to any kind of impurity. Among medical writers, however, to whom the word is now chiefly confined, it relates principally to impurities in the air, and is sometimes used indiscriminately with *Contagion* or *Infection*; which see. Under the former article we felt disposed to adopt Dr. Wilson's distinction between contagion and infection, *viz.* that the first should express a morbid poison, the application of which *may* excite disease, and the latter the condition of the subject after the morbid poison *has* induced such an effect.

This definition has the advantage of being consistent with the etymology of the two words, particularly of the latter, the allusion of which is to dyeing or staining: for as a colouring substance may come into contact with another, under such circumstances as to leave no stain, so a subject may be sometimes exposed to a contagion without being infected.

The variety of effects induced by different impurities of the air, renders it absolutely necessary to discriminate them with as much accuracy as possible. We shall, therefore, confine the term *miasma* to its original meaning, as used by Hippocrates, and, as all the rest have appropriate terms, we shall defer them to the articles in their order, namely, MORBID *Poisons*, PLAGUE, QUARANTINE, and TYPHUS.

The father of physic remarks, that there are three great causes of disease, food, drink, and air. The latter, he continues, is by far the most important, because we eat and drink only at certain times, and can even subsist for a few days without

without either, but are perpetually breathing, and cannot exist without air but for a few seconds. His dissertation on this subject relates principally to the temperature of the atmosphere, the aspect of places, according to the neighbouring mountains and seas, the various seasons of the year, climates, and manners of the inhabitants. Consequently but little information can be derived from him, concerning those most deleterious properties in some particular districts, which never could be visited but through the enterprising spirit of modern navigators. As this subject is now become particularly interesting, not only on account of our commercial connections, but from the importance of preserving the lives of our army and fleet, we shall not scruple to dwell upon it with some minuteness.

Though miasmata may be of different kinds, yet as they are only known by their effects on the human body, and the sources from which they are derived, we cannot venture to offer any other distinction. This distinction will be principally in degree, for, as Dr. Cullen remarks, the source seems to be universally from marshes, or moist ground acted on by heat. The properties of marshy soils in England is pretty generally understood, and their effects on the human body. We shall, therefore, only in general remark, that the ague induced by them is for the most part milder in spring than in autumn, and that for some time before and after the solstices, these places may be visited even by strangers with impunity. That all new comers are more certainly, and for the most part with more violence, affected than the constant residents; and that, from causes hitherto unknown, the disease is more general, more severe, and more fatal in some years than in others.

All these, however, like other pathological facts, must be admitted with certain limitations. The vernal agues, though so generally mild as to be formerly considered wholesome visitations to the constitution at that season, are sometimes severe; and the autumnal have in some seasons been found mild. There are constitutions which can never be inured to this kind of air, but are constantly and severely affected on each returning autumn; and there are new comers who remain with impunity till a severe season affects *them*, and probably many of the natives. At these times the season has been known to be protracted from the vernal almost to the autumnal period, and not to cease till winter has set in.

In England the intermittent fever is no longer an object of terror, since the introduction of the bark, and the safe use of some most powerful remedies; but most of all in proportion as the sources of the miasma have been diminished by the draining and improved cultivation of the soil. In Sydenham's time ague was among the epidemics of the metropolis, and the bills of mortality of those days shew how frequently it proved fatal. When London is now visited by ague, it is for the most part only sporadic, and in many instances, where it is least suspected, will be found to have been contracted by a residence in the country; for we shall presently have occasion to shew that miasma, received into the constitution, shews its effects at very uncertain, and sometimes very distant periods. There are, however, seasons when ague attacks those who have never left the town, probably by the air wafted from the marshes, in which cases the miasma is so diluted as to affect those only who are particularly susceptible. The years 1765, 1766, as well as 1782, are particularly marked as ague years in London, and even in 1808, the disease very often shewed itself. During each of these seasons a long prevalence of easterly winds was remarked. This, however, is too common an event during the summer and autumn to be considered a sufficient cause of itself. The truth is, the season was particularly sickly to the inhabitants of the low lands on the eastern side of the metropolis: and so powerful was the effect of the miasma at its source, that instead of the usual mild and regular intermittent, remittent and even continued fevers were very frequent and very fatal.

In the Netherlands the dreadful effects of this miasma have been too recently experienced to require, at this time, any considerable commentary. One might suppose such events would never be entirely forgotten, were it not that so many records are preserved, which appear to have been overlooked before the last unfortunate expedition to Walcheren. Not to mention the account given by sir John Pringle, whose medical character and long practice in the army have rendered him an oracle in these enquiries, we shall transcribe part of Dr. Wind's observations, who with his father had practised at Middleburgh for nearly 30 years.

"Towards the end of August, or beginning of September," says he, "is a continual burning fever, attended with a vomiting of bile, which is called the gall-sickness.—Foreigners in indigent circumstances, who are garrisoned in the adjacent places, are apt, after these fevers, to become dropsical, and many die." Dr. Lind, to whom we are indebted for the above extracts, further remarks, "the Scotch regiment in the Dutch service at Sluys has been known to bury their whole number in three years." Lind on Climates.

The insalubrity of the lower parts of Hungary, and still more of the Campania of Rome, are too well known to require our particular notice. We cannot, however, omit the history preserved by Lancisius, physician to pope Clement XI. "Thirty Romans of distinction of both sexes, having made an excursion upon a party of pleasure towards the mouth of the Tyber, the wind suddenly shifted and blew from the south over the putrid marshes, when twenty-nine were seized with tertian fever, only one escaping."

Though Africa has something terrific in its sound, yet it seems probable, that the northern coast, and for a considerable way inward, if we except the Lower Egypt, is as healthy as any part of the world. But the southern coasts, and particularly as we advance inward along the rivers, are so destructive to European constitutions, that probably neither our love of novelty, nor enterprising temper, will ever be sufficient to overcome these difficulties, so as to form a permanent settlement. In all these places the first rains are found so certainly deleterious, even to the natives, that they endeavour at these times to confine themselves to their houses, and to shut out as much as possible the external air. After a time, though the rain continues, the miasma is less pestilential, but soon after its cessation, as the surface of the ground becomes drier from its exposure to an almost vertical sun, the exhalations are pregnant with the exciting causes of all the tropical diseases.

In the countries leading from Africa to Asia, particularly Bassora, and other parts about Arabia, the English find the climate healthy, excepting at certain well-marked seasons.

Of the four presidentships in the East Indies, that of Bencoolen, in the island of Sumatra, is found the most unhealthy. Bengal, however, at certain seasons, is scarcely less fatal to the British, and often even to the Asiatic inhabitants. In the year 1762, it was well ascertained that 30,000 blacks and 800 Europeans died of the fevers of that country during the sickly season. Bombay has been rendered more healthy since an embankment, by which the overflowing of the sea has been prevented; and Madras has generally been considered a station not unfavourable to British constitutions.

Of

Of all the unhealthy ſpots in Aſia, Batavia is pretty generally allowed to be the worſt. The fatal miſtake, too common among Europeans, of attempting to aſſimilate the cuſtoms of a new country to their own, is ſaid very much to have increaſed the inſalubrity of that ſettlement. It ſeems hardly conſiſtent with common underſtanding, that the Dutch, after the experience of ſo many years, ſhould ſtill perſevere in preſerving their dykes, to leſſen the expence of carriage at the charge of human life. Yet ſuch we are aſſured is the caſe. Among the many inſtances of mortality, for which that colony is ſo well known, we ſhall mention only two. In the year 1763, the Falmouth, a ſhip of 50 guns, was at Batavia for about ſix months, during which time ſhe buried 75 of her crew, and 100 ſoldiers of the 79th, who had embarked on board her; every ſoul on board having been ſeized with fever, excepting only the captain. In the year 1764, the Panther, during a very ſhort ſtay, buried 25 of her men, among whom was the commander, captain Matthewſon. Nor was the ſickneſs confined to the ſhip's company. The whole city exhibited no other ſcene but diſeaſe and death. Streets crowded with funerals, bells tolling from morning till night, and horſes jaded with dragging hearſes to the burial places.

Though we have remarked above the great probability that the nature of this miaſma is every where the ſame, as its ſources are evidently ſimilar, yet it is right to obſerve that its effects on the human body are ſomewhat diverſified in different quarters of the globe. Throughout the whole of Hindooſtan, and northward, as far as the Britiſh have formed any ſettlements, the liver ſeems to be principally affected, and the principal danger to ariſe from the too high action of its veſſels, and even the entire diſorganization of that important viſcus.

On the ſouthern coaſt of Africa, and along the margins of its extenſive rivers, the liver is the organ principally affected, and rarely, if ever, recovers its due functions, where the injury has been conſiderable. The liver ſuffers in the tropical regions of the Weſt, though not with the ſame uniformity. In the ſouthern parts of the N. weſtern hemiſphere, and in all the Weſt India iſlands, the liver is often affected, but in many inſtances of the moſt violent fevers in this part of the world, it may be doubted whether the ſtomach is not primarily affected, and the liver only ſympathetically, the black vomit being now pretty generally admitted to be derived from the ſtomach, and the yellow colour of the ſkin not making an eſſential character of the fever known by that name. It is not improbable that the Zealand diſeaſe, though diſtinguiſhed by the name of the gall-ſickneſs, may only affect the liver in common with the other viſcera. It is certain that the brain ſuffers much in this diſeaſe, and not uncommonly thoſe who eſcape with life remain for months, and ſometimes years, with impaired memory and even deranged intellect.

In England, the enlargement of the ſpleen is the moſt common effect; the conſequences of which are very rarely conſiderable, if the diſeaſe is not ſuffered to remain long without relief.

The moſt important conſideration, and the moſt to our preſent purpoſe, is the means of preventing the exiſtence of miaſma, or, where that cannot be done, of avoiding its effects. The firſt, it is evident, can only be accompliſhed by draining the low grounds. This may always be attained where the ſurface is above the level of the ſea, or ſtill eaſier, if above the level of a neighbouring river. What has been done in this way in our iſland is hardly credible. The attempts to drain the Pontine marſhes are not leſs honourable to human induſtry; and if we can believe the preſent accounts, it would appear that ſuch attempts are now perſevered in with more ſteadineſs than ever. The vaſt embankments made by cardinal Richelieu on the coaſt of Rochelle, in the bay of Biſcay, are well known, and muſt for ever live in the writings of Voltaire. When, as is often the caſe, a town has been conſtructed on a hill by the banks of a river, if the population, after ſpreading along the ſide of the river, ſhould gradually extend itſelf over the back of the hill, at right angles with the river of the ſea-coaſt, there will always be danger of water ſtagnating in the valley behind. The force of the miaſma from this cauſe will be greatly increaſed by the illuvies from the cottages which uſually are the firſt erections at theſe extremities. To this London at one time owed, if not its agues, at leaſt its vernal and autumnal fevers, as deſcribed by Sydenham. The great fire proved the means of forming a proper level as far as that formidable, though fortunate event extended; but it was not till within theſe laſt thirty years, that the northern part of the city, or rather its ſuburbs, has been drained by a ſewer, which, if ever London ſhould ſhare the fate of Carthage, will immortalize the well-directed induſtry and enterprize of its inhabitants. This ſewer, which is cylindrical, not leſs than ſix feet in diameter, and in ſome parts more than twenty feet below the ſurface, was carried through ſome of the narroweſt ſtreets, conſiderably below the foundations of the houſes; to protect which, ſuch a quantity of timber and planks was buried as would form almoſt an impaſſable grove if it were all to appear above ground. The ſudden growth of the cities in North America has produced the moſt fatal effects in proportion as the heat of the ſolſtitial and autumnal ſun is greater, and as the increaſe of their towns has outrun moſt others in every part of the world. This is now ſo well underſtood, that the more prudent inhabitants of the large towns are attending much more to ſecuring themſelves from yellow fever by draining, than by the enforcement of quarantines.

In our own country it is incredible to what extent the ſpirit of draining has extended; beſides thoſe large undertakings which can only be brought about by the union of whole counties. Sometimes aſſiſted, or at leaſt empowered, by parliamentary authority, every enterpriſing farmer, whoſe lands are of any extent, has his *underground drain* wherever it is neceſſary, and can be accompliſhed.

We are not, however, to conſider all the danger as removed when an old moraſs is drained: for even if ſuch land is ſecured from being overflowed under the moſt unfavourable ſeaſons, which is rarely the caſe, yet whenever it is firſt converted from paſture to arable, fevers are in ſome places excited much more formidable than the common intermittent. This leads us to the ſecond conſideration, that of avoiding the effects of miaſma where the cauſe cannot be entirely removed.

The firſt part of the inquiry here muſt be, whether the diſeaſe is infectious? If we reaſon from cauſe to effect, we ſhould conceive that a diſeaſe derived from exhalations from the earth could only be excited by a ſimilar cauſe, and, conſequently, that a ſick perſon removed from the ſource could convey no contagion to others. But we ſhould recollect that he may arrive with his clothes ſo impregnated with the effluvia of ſuch miaſma, as to be dangerous to thoſe who firſt receive him, as we find perſons often carry with them the ſmell of their particular occupation or habits. To determine, therefore, that a diſeaſe is contagious, it will be neceſſary to prove that others have been infected who have been expoſed to the ſick only, and neither to the ſeat of the miaſma

miasma itself, nor to such substances as may contain what is called the fomes.

At the source of the disease we shall find the greatest difficulty in determining the question; for where one general cause affects several, it will often be difficult to say whether an attendant on the sick has taken the disease from them, or from the same common cause that has affected the whole neighbourhood. This difficulty we shall see is much increased when we come to the article TYPHUS. At present, we shall only make two general remarks:

First, that wherever a number of persons are collected, if sickness of any kind prevails among them, a kind of infectious air is generated, which is the source of typhus fever.

Secondly; that during the prevalence of any epidemic, those who are affected with any other disease are generally the earliest seized with the epidemic, their reduced state of health rendering them less able to resist the force of the miasma; and as two diseases cannot occupy the same constitution at the same time, the consequence must often be, that their former complaint gives way to the reigning disease.

It may seem remarkable that this chain of events should be more accurately attended to by the ancient historians than by modern physicians; but the terms in which they explain themselves may shew the cause of this difference. Thucydides makes no mention of contagion till the advanced period of the plague in Athens; and Livy expressly says, that at first the men became sick from the badness of the season, and the unhealthiness of the place, and that afterwards the attendance on the sick rendered disease more common. By this evidently marking, that the accumulation of the sick had induced the hospital, in addition to the endemic, fever. See CONTAGION.

We have been obliged to anticipate this part of a succeeding article, because it involves a question of the highest importance, in avoiding the *effects* of miasmata where the *cause* cannot be entirely removed. If the disease induced by such a cause had a contagious property similar to small-pox and measles (see Dr. Cleghorn on the Diseases of Minorca), the probability is, that it would not cease till it has invaded all who are exposed to it; and that should any leave the country with the disease, or its fomes, the consequences would be equally general in every place to which the sick should be carried. In this case the only remedy would be to confine the sick and healthy to the spot, and not suffer them to escape till the disease has entirely ceased; after which there should be an universal ablution and purification before any general intercourse should take place. But if the disease is known to arise only from the season and the nature of the country; if from experience it should be ascertained that with a change of season the disease will cease; if it is further found by experience that no infection can be traced till the number and accumulation of the sick has produced a hospital or camp fever; if all this can be ascertained, surely the first step should be to encourage all the inhabitants instantly to quit so fatal a spot, and not to return to it till a change of season has produced a change in the properties of the atmosphere. It is much to be regretted that this discrimination has been so little attended to in the late controversies concerning the yellow fever in the West Indies, as well as the epidemics, which have visited Gibraltar and the various cities in the south of Spain. In America the question seems to be unfolding itself; and, as we before remarked, the terror of contagion is gradually giving way to a more rational precaution.

Where a country has been drained, after the ploughing of which the exhalations are found deleterious, no remedy remains but to confine this branch of husbandry to the solstices, afterwards leaving the broken ground to the effects of air and rain. This caution should be extended to the opening of new land wherever the surface is formed of an accumulation of autumnal leaves impeding the current of rain, and annually putrifying for a considerable number of years.

When vessels are cruising, or moored in the neighbourhood of swamps or thick woods, particularly in tropical regions and at dangerous seasons, the sailors should never be allowed to sleep on deck, and as few as possible should remain there after sun-set. If it is necessary to wood or water, every endeavour should be used to employ for this purpose the aborigines of the place, or negroes, whose constitutions are seldom affected by such miasmata, and when they are, the effect rarely exceeds that of the common tertian, which readily gives way to the usual remedies. If it is absolutely necessary to send the crew on shore, they should always return before sun-set and sleep on board.

When, as is often the case, it is found necessary to conduct a siege on one of these unwholesome spots, the first consideration should be to commence the operations at the least dangerous season. At this time the greatest attention should be paid to raising batteries as high as possible, consistently with the safety of the besieged, the miasma being always found to be most powerful the nearer to the soil. At the same time the level of the ground should be examined, to see how far it will admit of draining without turning up too much of the surface. When the sickly season arrives, as few men as the service will permit should be left on the ground during night, who, on the succeeding morning, and for several days after, should be carefully examined by the medical officer, that the first approaches of disease may be instantly met. Such men as are found best to withstand the effects of the miasma should be oftenest on duty. Above all, the hospitals should be prepared before they are wanted, and in a situation as remote as possible from the source of disease. Where the situation of the place will admit, it would be best to use floating hospitals, or hospital-ships, which in fair weather might make frequent cruises with their port-holes and scutcheons open, and with as many of the men on deck as can be moved thither. The attendants should be selected among the convalescents.

By attention to these rules, many expeditions might be much more successful, and much less wasteful of human life: many lands might be cultivated by those who would enjoy the benefit of their bold and enterprising undertaking, and many lives rendered comfortable which at this time are dragged on with misery and resigned without regret. See EPIDEMIC; FEVER, *Causes of*; HEALTH, &c.

MIATA, in *Geography*, one of the Society islands in the S. Pacific ocean. S. lat. 7° 52′. W. long. 148° 6′.

MIA-TAU, a cluster of small islands in the Chinese sea, near the coast of Chang-tong; extending from six to 36 miles N. of Tong-tcheou.

MIATHIR, a town of Morocco, in the province of Duquella, near a mountain of the same name.

MIAU-SHEHR, a town of Persia, in the province of Ghilan; 50 miles N.W. of Reshd.

MICA, *Glimmer*, Wern.; *Mica*, Haüy.

The usual colour of this mineral is grey, which occurs yellowish, greenish, smoke, and ash-grey; the yellowish-grey passes into yellowish and greenish-white, and into silvery, and also into wax-yellow, brass and gold-yellow, reddish, pinchbeck,

pinchbeck, and blackiſh-brown; the greeniſh-grey paſſes into mountain and aſparagus-green, alſo into leek-green and blackiſh-green; the aſh-grey is found of various ſhades, and paſſes into perfect black. Sometimes ſeveral colours occur together in the ſame piece. Upon the whole the colour is found conſiderably to vary, according to the different degrees of tranſparency of the ſpecimen. The black variety appears brown, when placed between the eye and the light. The colour of the powder is always greyiſh-white.

Mica is found principally diſſeminated and in thin layers alternating with other foſſils, ſuch as quartz and feldſpar, in gneiſs, &c.; but it alſo frequently occurs in maſs and cryſtallized.

Its primitive form is the ſhort, ſtraight, rhomboidal priſm of 120° and 60°. Integrant molecule the ſame.

The principal cryſtallizations are; 1. The ſhort ſtraight four-ſided priſm with rhomboidal planes; being the primitive form (Mica *primitif*, Haüy, pl. 60, fig. 205.) Theſe priſms are generally ſo low, that they may be conſidered as four-ſided tables. They are eaſily and diſtinctly divided in a direction parallel to the baſes; the cleavage in the other direction is generally indiſtinct.

2. The regular ſix-ſided priſm, generally very low, ſo as to appear tabular. (Mica *priſmatique*, Haüy, ib. fig. 207.)

3. The lengthened rectangular table (Mica *binaire*, Haüy, ib. fig. 208.)

4. The low regular ſix-ſided priſm with truncated terminal edges. (Mica *annulaire*, Haüy, ib. 206.)

The cryſtals are ſometimes large, but generally middle-ſized and ſmall; they are ſometimes found ſeparate, but oftener grown together; they are now and then ſeen faſcicularly aggregated and in roſes. The lateral planes of the cryſtals are ſmooth and ſplendent; the terminal planes ſhining. Internally ſpecular ſplendent; luſtre ſometimes reſinous, ſometimes pearly, often ſemi-metallic and metallic; in the uncryſtallized mica, the luſtre of the planes of fracture is generally leſs intenſe.

Fracture partly ſtraight, oftener curved, or undulatingly foliated. The foliated fracture ſometimes paſſes into the broad and narrow radiated, which is partly parallel, partly faſcicularly or ſtellularly diverging. The fractural ſurface, particularly that of the broad radiated variety, is ſometimes marked with feather-like ſtreaks. Fragments tabular. The maſſive ſhews coarſe, large and ſmall-grained diſtinct concretions; the radiated is compoſed of cuneiform columnar concretions.

The common maſſive varieties of mica are opaque, or only tranſlucent on the edges; the detached folia are moſtly tranſlucent and even tranſparent. Some cryſtallized varieties are perfectly tranſparent in all directions. The ſeparation of the folia from each other, though not obſervable to the eye, is generally the cauſe of the loſs of tranſparency.

It is ſemi-hard, approaching to ſoft; eaſily diviſible in the direction of the folia, and may be eaſily cut with a knife; it feels ſmooth, not unctuous, and is elaſtic flexible. Specific gravity 2.654—2.634, Haüy; 2.726, Karſt; 2.767, Kirw.; 2.866, Reuſs; 2.934, Blumenb.

Before the blowpipe, the dark coloured varieties (according to Wiedenmann) take a pinchbeck or braſs-yellow hue, but they are nearly as difficultly fuſible into enamel as the colourleſs varieties. The enamel of black coloured mica affects the magnetic needle.

The analyſes which we poſſeſs of this ſubſtance vary conſiderably, at leaſt with reſpect to the relative quantity of the conſtituent parts of the ſeveral varieties.

	Muſcovy Glaſs.	Common.	From Zinnwald.	Muſcovy Glaſs.	Black Siber

This very common but remarkable foſſil, forms a principal ingredient of ſome of thoſe rocks which belong to the primitive ſlate formation of Werner, particularly granite, gneiſs, and mica ſlate: it is alſo found in primitive limeſtone, and in grau-wacke. Nor is it wanting in the trapp-formation, as in ſienite, porphyry, greenſtone, baſalt, wacke; though in the laſt mentioned rocks it is probably derived from primitive rocks by diſintegration. In ſome caſes it is known to form entire beds, like thoſe at Zinnwald. It rarely occurs in veins, ſuch as thoſe belonging to the tin-ſtone formation in Bohemia and Saxony.

The localities of mica being thoſe of the widely extended primitive rocks above-mentioned, need not to be particulariſed. The mica in large plates, called Muſcovy glaſs, from the uſe to which it is applied, occurs in granite in ſeveral parts of Siberia, and on the ſhores of the Caſpian, at Uda, on the borders of the Upper Tunguſka, the lake Jeneſey, Baikal, in Georgia, &c.

By far the greateſt part of the large foliated mica is employed in the Ruſſian empire, eſpecially in Siberia, where it is generally uſed inſtead of glaſs for windows. The poorer claſſes employ the ſmall plates, which they ſow together. It is ſaid to have been a ſubſtitute for glaſs in the windows of Ruſſian men of war, as being leſs liable to be broken by the concuſſion of the air during the diſcharge of heavy artillery; but to this uſe mica is no longer applied. We find that in the year 1781, upwards of 200 pud of this variety of mica were exported from Peterſburg to Lubeck, and 2721 pud to Great Britain. Beckmann, who makes mention of this exportation, is at a loſs to gueſs the uſe in which theſe 116,800 pounds of Muſcovy glaſs may have been employed.

According to Ellis's account, the ſame kind of mica occurs in large plates in Hudſon's bay; and Kalm found it in Pennſylvania, in leaves of half a yard in diameter, and of equal tranſparency with the Siberian variety. Indeed the Swedes, who from 1630 to 1655 had colonies in New Jerſey and Pennſylvania, employed it, as the Ruſſians do, inſtead of glaſs in the windows.

The tenuity of the laminæ of the large foliated varieties is ſuch, that, according to Haüy's calculation, a piece $\frac{4}{9}$ths of a line in thickneſs, may be divided into 23,255 ſeparate laminæ. This property, and the facility with which it is cut, render the Muſcovy glaſs peculiarly proper for incloſing minute objects to be viewed by the microſcope.

MICA-*ſlate, Glimmer-ſchiefer*, Werner; *Micaceous ſhiſtus*, Kirwan; *Schiſte micacé*, Broch.

This primitive rock is eſſentially compoſed of mica and quartz, diſpoſed in layers, which are more diſtinct than thoſe of gneiſs, into which it is frequently ſeen to form a tranſition. The colour of the mica, which generally forms the

 predominant

predominant part, is usually of a grey colour, mixed with greenish; the quartz is almost always white.

This rock, which is of great importance to the miner, as being particularly rich in ores, contains also frequently other minerals, particularly common and noble garnets, which may even be considered as forming an essential component part of mica slate; shorl, both the common and tourmaline (such as that of Dunkeld and Blair-in-Athol in Scotland), kyanite (which has been found in the varieties from Mainland, one of the Shetland islands, and near Banchory in Aberdeenshire), rutile (that of Salzburg, Hungary, &c.), feldspar, but only in single grains.

Besides the common mica slate, which is straight, and rather thick slaty, the Wernerian geognosians distinguish three other varieties, *viz.* the undulated mica slate, which has not been found to include other substances; the talcky mica slate, which is straight slaty, composed of green mica, and traversed by thick layers of quartz; and lastly, the fine slaty variety, which forms a transition into clay slate, which rests on it; it is generally of a greyish-yellow colour, and almost entirely unmixed with quartz.

As mica slate passes on one side into clay slate, (the next rock in succession,) in the same manner it forms a very distinct transition into gneiss, on which it rests; the outgoings of its strata being lower than those of the latter, and higher than those of the clay slate, which usually cover them. It surrounds the older rocks in mantle-shaped stratification.

The mica slate mountains, which are generally much less craggy and bold than those of gneiss, contain far more foreign beds than both granite and gneiss mountains; the most remarkable beds observed in them are those of granular limestone, of hornblende slate, hornblende rock, and actinote; as likewise galena, copper and iron pyrites, magnetic iron-stone, and other ores. The greatest part of the metalliferous mines of Sweden and Norway, and several of those of Hungary and Saxony, are situated in this rock.

Mica slate constitutes considerable mountains in most parts of Europe, and also, according to Humboldt, in South America. In Scotland, it occurs abundantly in the valley between Dunkeld and Blair-in-Athol, on the mountain of Schehallion, in the island of Arran, the island of Jura and Isla, &c. Jameson.

It is often employed for constructing or lining furnaces, whence it has been called *Gestellstein*, or *Saxum fornacum*; names which are, however, given to several other fossil rocks applied to the same purpose.

MICABA, in *Geography*, a town of Japan, in the island of Niphon; 100 miles N.N.E. of Meaco.

MICAH, in *Scripture History*, the seventh in order of the twelve minor prophets. He is called the "Morasthite," or of "Moresa," a village near the city of Eleutheropolis, in the south of Judah. He was nearly contemporary with Isaiah, and has some expressions in common with him: compare Isaiah, ii. 12. with Micah, iv. 1; and Isaiah, xii. 15. with Micah, iv. 13. St. Jerom says, that Micah was buried at Morasthi, and Sozomen says, that his tomb was discovered to Zebennus, bishop of Eleutheropolis, in the reign of Theodosius the Great. Some have confounded Micah with Micaiah, son of Imlah, who was of Ephraim, and who prophesied in the time of king Ahab. Micah prophesied under Jotham, Ahaz, and Hezekiah for about 56 years, from the beginning of the reign of Jotham, or 754 B.C., to the last year of Hezekiah 698 B.C. His prophecy contains seven chapters; in which the first foretells the calamities of Samaria; afterwards he prophesies against Judah, and having exclaimed against the iniquities of Samaria, he foretells the captivity of the 10 tribes, and their return. After a pathetic invective against the princes of the house of Jacob, and the judges of the house of Israel, he speaks of the birth and reign of the Messiah. The two last chapters contain an invective against the iniquities of Samaria; after which he predicts the fall of Babylon, the re-establishment of Israel, their happiness, &c. in such lofty terms, as chiefly agree with the state of the Christian church. The style of Micah is for the most part close, forcible, pointed, and concise; sometimes approaching the obscurity of Hosea; in many parts animated and sublime, and in general truly poetical.

MICARELLE, in *Mineralogy*. See PINITE.

MICE, in *Gardening*, a sort of vermin which are highly destructive to several sorts of garden crops, such as peas, beans, &c. in the early spring, and lettuces, melons, and cucumbers in frames in the winter season. When discovered they should of course be immediately destroyed, either by traps or some other means. See VERMIN.

The author of "Phytologia" has suggested, that "the destruction of grain after it is sown by field-mice, which mine their way very quickly under newly ploughed lands near the surface, is supposed by Mr. Wagstaff, in the papers of the Bath Society, to be effected in some seasons to a very great extent. And that the tussocks of wheat, seen to arise in many fields, are owing to the granaries of these diminutive animals, which he has found to contain nearly a hatful of corn, which grows into a tuft, if the owner becomes accidentally destroyed. It is also further asserted, that they feed much on the young plants, as they arise from the seed, and multiply at that time very fast. He detects their habitations by small mounds of earth being thrown up, on or near the apertures of their dwellings, or of the passages which lead to their nests or granaries; and by following the course of these passages, he found and destroyed the parents and the progeny." He likewise "recommends the taking up and dividing the tussocks of wheat, thus sown in the autumn by the field-mice, and transplanting them in the spring; and also to thin other parts of a young crop, as they appear too thickly sown, which he esteems an advantageous practice."

And it is found, that "acorns when sown, as well as garden beans, and peas, are liable to be dug up or devoured by these voracious little animals, which may be destroyed by traps baited with cheese; or best of all, by the encouragement of the breed of owls, so active in the pursuit of nocturnal vermin, and thence so useful to the gardener and farmer, who still permit their servants and children to destroy both their eggs and callow young."

These little plunderers may be readily destroyed by the use of the poisonous substance, usually known by the title of *nux vomica*, which should be finely rasped down, and mixed with some sort of meal or other similar material, of which they are fond.

MICELLA, in *Geography*, one of the smaller Molucca islands.

MICHAEL I., in *Biography*, surnamed *Rhangabe*, emperor of the East, was son of Theophylact, governor of the isles, and married Procopia, daughter of the emperor Nicephorus I., by whom he was raised to the office of great master of the palace. He was present at the battle against the Bulgarians, in which Nicephorus was slain A.D. 811. Stauracius, the son of the emperor, had received a severe wound in the battle, and was, besides, universally hated. The empire was therefore offered to Michael, who at first hesitated to accept it, but finding that Stauracius designed to put out his eyes, he obliged him to retire to a convent, where

where he ſoon after died. Michael was poſſeſſed of private virtues, but wanted vigour to controul the ſpirit of his wife, who excited the indignation of the ſoldiers, by appearing at the head of the army, and it was generally acknowledged that he was deficient in the military talents requiſite at ſuch a criſis. He marched againſt the Bulgarians, ventured upon an engagement, in which he was defeated, and returned with diſgrace to Conſtantinople, leaving a diſcontented army under the command of diſaffected generals. By their intrigues the ſoldiery proceeded to the depoſition of Michael, and offered the imperial crown to Leo the Armenian. The ſenate, the clergy, and the people of the capital ſtill adhered to Michael, but he declared that not a drop of blood ſhould be ſhed on his account, and reſigning the enſigns of ſovereignty retired with his family to a monaſtery, having filled the throne leſs than two years. He was permitted to live in peace, and in a religious retreat, during thirty-two years, which he ſurvived his abdication. Gibbon. Univer. Hiſt.

Michael II., ſurnamed the *Stammerer*, a native of Phrygia, was educated among the Jews and heretical Chriſtians, and during the early period of his life, he adopted opinions that probably rendered him obnoxious among thoſe who ſtyled themſelves of the orthodox faith. When he attained to years of diſcretion he was appointed an officer under Nicephorus, and was a principal inſtrument in raiſing to the throne Leo the Armenian. During the reign of this emperor he was employed in high offices, but having incurred the ſuſpicion of conſpiring againſt his ſovereign, he was arreſted and brought to trial. At that period, conviction and accuſation followed each other of courſe, and Michael was condemned to the cruel death of being burnt in the furnace of the private baths. The execution of this ſentence, which had been fixed for Chriſtmas-day, was ſuſpended through devout ſcruples of the empreſs, and in the mean time Michael informed his friends of his danger, and threatened them with detection, unleſs they effected his deliverance. The hope of ſelf-preſervation excited them to exertion, and in conſequence of it, Leo was dethroned and murdered, but Michael with fetters on his legs was ſeated on the imperial throne in December 820. One of his firſt acts was to reverſe the late ſovereign's decrees, by recalling a number of biſhops and other eccleſiaſtics who had been baniſhed, for refuſing to comply with the late emperor's edict againſt the worſhip of images. Notwithſtanding this conduct, Michael himſelf was by no means friendly to this kind of worſhip, and tolerated it only without the precincts of the capital. He is therefore reckoned among the enemies of the Catholic church, and the calamities of his reign have been imputed to his hereſy. A revolt in the Aſiatic provinces was the commencement of a civil war, which nearly ſubverted the throne. One Thomas, at the head of a vaſt army of barbarians, over-ran Leſſer Aſia and Syria, defeated the troops ſent againſt him, and laid ſiege to Conſtantinople. At length, however, he was unſucceſsful in his efforts againſt the eſtabliſhed power, and falling into the emperor's hand, he was put to a cruel death. During theſe internal commotions, the Saracens landed in Crete, and formed a ſettlement in that iſland, from which Michael in vain attempted to expel them. During the ſixth year of his reign he married, from a convent, Euphroſyne, the daughter of Conſtantine VI., which has been imputed to him as a moſt irreligious act; it ſufficed likewiſe as an example to one of his officers, Euphemius, to gratify a licentious paſſion, by forcibly taking a nun from her convent in Sicily, which was the cauſe of the loſs of that iſland. Euphemius, in order to avoid puniſhment, fled to the Saracens in Africa, and returning with a large body of troops of that nation, endeavoured to gain poſſeſſion of Syracuſe. He loſt his life in the attempt; but the Saracens, thus introduced into Sicily, by degrees made themſelves maſters of it, as well as of the neighbouring provinces of Italy. Michael, after an unfortunate reign of nearly nine years, died in 829, and was ſucceeded by his ſon Theophilus.

Michael III., grandſon of the preceding, was born in 836, and ſucceeded his father Theophilus in 842, when he was only ſix years of age. He had been educated in habits of piety and virtue by his mother Theodora, but as he grew up, he abandoned all the early impreſſions of his childiſh years, became famous for the diſſolute courſe of his life, and deſervedly obtained a place among the moſt unworthy emperors. He did not aſſume the reins of government till he was in his twentieth year, when Theodora and her daughters were obliged to quit the court and enter a monaſtery, where ſhe ſoon died of a broken heart. Michael ſeemed to rejoice in the event: while his virtuous mother was alive, her conduct was probably ſome reſtraint to his paſſions, but as ſoon as death had levelled her with the duſt, her worthleſs ſon was anxious to ſurpaſs even a Nero in his profligacy and buffoonery. In imitation of that prince, whoſe name and memory are devoted to infamy, he purſued the ſports of the circus, and took into his favour and confidence thoſe who were deemed the moſt ſkilful charioteers. He was perpetually guilty of exceſs in wine, and, in the hours of his brutal intoxication, iſſued the moſt ſanguinary commands, which his ſervants, more humane than their maſter, frequently ventured to diſobey. It was one of his amuſements to profane with mock ſolemnities the moſt ſacred ordinances of religion. Amidſt theſe follies he undertook an expedition to the Euphrates againſt the Saracens, who put him and his army to flight. He was long under the influence of Bardas, whom he raiſed to the dignity of Cæſar, and by whoſe advice the patriarch Ignatius was depoſed and impriſoned, and the learned Photius placed in his chair. In 806, Michael was induced by Bardas to undertake an expedition into Crete, to oppoſe the ravages of the Saracens, who from that iſland had made a deſcent into Thrace. This advice proved fatal to the favourite and miniſter, for having excited the jealouſy of the emperor, he ordered him to be ſtabbed in the tent of audience. This cruel and treacherous deed excited the indignation of the ſoldiers, and Michael returned privately to Conſtantinople, where he ſoon after raiſed Baſil the Macedonian, who had been the inſtrument in the aſſaſſination of Bardas, to a partnerſhip with him in the throne, and devolved upon him all the buſineſs of the ſtate. Baſil, who it is ſaid, had juſt ideas of the imperial character and duties, endeavoured by remonſtrances to reclaim Michael from his abandoned courſe of conduct. But his habits were too deeply rooted to admit of a change, and it was determined to ruin the monitor. Baſil was fortunately apprized of his danger, and reſolved to ſtrike the firſt blow, and with the aid of accomplices murdered him while aſleep, and in a ſtate of intoxication, in the year 867, in the thirty-firſt year of his age. Univer. Hiſt. Gibbon.

Michael IV., a native of Paphlagonia, of obſcure birth, was brought up to the trade of a money-changer, but being introduced at the court of Romanus III., his perſonal beauty caught the eye of the licentious empreſs Zoe, who made him her chamberlain, and exacted from him attentions inconſiſtent with the homage which he owed to his ſovereign. At length the empreſs, advancing from one degree of guilt to another, poiſoned her huſband, celebrated her nuptials with Michael, and raiſed him to a partnerſhip in the throne.

This event was accomplished in the year 1034. The empress was disappointed in the expectations which her passions had excited, as well on account of the ill state of health which her husband fell into, as on account of the torture which he experienced from a consciousness of the crimes in which he had participated. All authority soon devolved into the hands of his brother John, an eunuch, who had originally introduced him to court, and who quickly reduced Zoe to a state of insignificance, surrounded with spies, and made a prisoner in her own palace. Michael began now to endeavour to atone for his guilt by liberality to the poor, and by the endowment of churches and hospitals. A revolt of the Bulgarians roused him to exertion; he headed his army, and though in his first expedition he was obliged to retreat with disgrace, in a second encounter he was more successful, and returned in triumph to Constantinople. Warned with the approach of death, he retired to a monastery, which he had himself founded, and in which he died, in the year 1041: having first nominated as a successor his sister's son,

MICHAEL V., surnamed *Calaphates*, from his father's occupation of a caulker of ships. He was proclaimed emperor immediately on the death of his uncle, but his reign was of very short duration. His first sovereign decrees were the banishment of his uncle John, the eunuch, and the confinement of Zoe to a monastery. The people, who generally take part with the oppressed, revolted at these acts of tyranny, recalled Zoe and her sister Theodora, and proclaimed them joint sovereigns. Michael was now glad to take refuge in a monastery, and assumed the religious habit, hoping to escape farther injury, but at the instance of Theodora he was deprived of his sight, an usual though horrible punishment at that period, and, with all his relations and adherents, was sent into banishment, having occupied the throne only four months. Gibbon. Univer. Hist.

MICHAEL VI., surnamed *Stratioticus*, was appointed by the empress Theodora as her successor on the throne, which he ascended in the year 1056. He was already advanced in years, and enjoyed a reputation for military talents, but was wholly unacquainted with the art of government, its nature and principles. He gave himself up to the dominion of his eunuchs, who made an ill use of their influence, so that a conspiracy was excited, and Isaac Comnenus was elevated to the imperial dignity. The new emperor assembled an army in the eastern provinces, with which he proceeded towards the capital. In the neighbourhood of Nice he was met by the forces of Michael, and an engagement ensued, in which the latter were completely overthrown. Michael now saw that he had in vain exacted an oath from the citizens of Constantinople never to acknowledge Comnenus for emperor. At the approach of the conqueror, a decree was unanimously passed, investing him with the imperial title and authority, and a deputation of bishops was sent to Michael, commanding him formally to renounce the sovereignty. "What," said the fallen prince, "will you give me in exchange for the empire?" "The kingdom of heaven," they replied. He submitted and retired to a monastery, after a reign of about a year. Gibbon. Univer. Hist.

MICHAEL VII., surnamed *Parapinaces*, the son of Constantine XI., was proclaimed emperor in the year 1071, on the defeat and capture, by the Turks, of Romanus Diogenes. He had been well educated, and had studied philosophy and rhetoric, but was unfit for the cares of the empire, which devolved upon his uncle. He was charged with diminishing the measure of corn for his own emolument, during a scarcity, which fixed upon him his reproachful surname. An invasion of the Turks, and a revolt among his own people, forced him to resign his crown, and retire to a monastery, after a reign of six years and a half. He died at Ephesus, having been consecrated bishop of that see. Univer. Hist.

MICHAEL VIII., of the noble family of Palæologi, was brought up to the military service, and obtained popularity and distinction by the graces of his person and manners. In his youth he was commander of the French mercenaries in the employ of the empire. During the reign of John Vataces he was accused of ambitious designs, but cleared himself so well of the charge, that he was not only honourably acquitted, but made governor of Nice. In the year 1255, new charges were brought against him, and he privately withdrew to the Turkish sultan of Iconium, by whom he was honourably received, and placed at the head of a body of Greeks in Turkish pay, with whom he distinguished himself against the Tartars. After this he was recalled by the emperor Theodore, and at his death, in 1259, he recommended him as the guardian and protector of his son John, who was then a minor. He now assumed the title of grand-duke, and the office of regent of the empire was delegated to him. His ambition began to display itself, and he employed every art to give splendour to his administration, and impress the people with the idea of his fitness for the throne. The news of a victory over the despot of Epirus was the signal for the people in Michael's interest to salute him with the title of emperor, and it was agreed that he and the young prince John should wear the purple conjointly. The patriarch, with great reluctance, was induced to place the imperial crown upon the head of Michael alone, while John walked in his train, distinguished only by a diadem of very inferior worth. This was in 1260, and in the following year Michael received the welcome intelligence of the recovery of Constantinople, to which city he and his court removed from Nice. He shewed that he was capable of acting on the most liberal principles: he restored the city to its ancient splendour, and encouraged the continued residence of the Genoese, Venetian, and Pisan merchants; but having attained to a good share of popularity, he felt himself sufficiently strong to commence a new era by reigning sole emperor. To remove his competitor from the chance of opposing his projects, he caused his sight to be destroyed. For this infamous act of barbarity, the patriarch Arsenius pronounced a sentence of excommunication against him, which he refused to recal, unless he would exhibit signs of repentance by abdicating his throne. The emperor, trusting to his own strength, deposed and banished the patriarch, but he had attached to his cause so large a party among the clergy, that a schism in the Greek church was the consequence, which continued a number of years. Michael, as a warrior and politician, was successful in many of his projects; he recovered several of the finest islands in the Archipelago, as well as part of the Morea, from the Franks; but on the other hand, the despot of Epirus, and the king of Bulgaria, made incursions into Thrace, and laid waste the country with fire and sword. These and many other troubles induced him to seek the favour of the Roman see, by proposing an union between the Greek and Latin churches, with an acknowledgment of the supremacy of Rome. This was effected at the general council of Lyons, under pope Gregory X., in 1274, an act which extremely disgusted his own subjects, and he was obliged to institute a violent persecution against the schismatic Greeks, in order to preserve the semblance of an union. This so irritated his own family, and the inhabitants of Constantinople, that he was eventually excommunicated by pope Martin IV., for the share which it was known he had in the massacre of the French in Sicily, known

by

by the name of the Sicilian vespers. He died in 1283, at the age of 58, and in the 24th year of his reign. His son Andronicus, whom he had associated with himself in the empire, instantly dissolved the union of the churches, and refused his father Christian burial. Gibbon. Univer. Hist.

Michael, Feodorovitch, czar of Russia, was son of Theodore Nikiliz Romanof, an archbishop of Rostock. After the dethronement of the czar Zuski, in 1610, a party of Russian nobles offered the crown to Ladislaus, prince of Poland, and a Polish garrison had been admitted into Moscow, which was the occasion of much bloodshed. It was after some time expelled by a more numerous party of Russians, who elected Michael, the subject of this article, then a youth of seventeen, as new czar. He was distinguished by his descent from a daughter of Ivan Vasilevitch, and rendered dear to the nation by the virtues of his father. At the time of the election he was in a monastery with his mother, while his father was a prisoner in Poland; and when the proposal was made to raise him to the throne, the unhappy fate of some of the late czars filled his mother with such apprehensions, that she did every thing in her power to get him excused the intended honour. The senate, however, persisted in their choice, and Michael was solemnly elected in 1613. He was immediately involved in a war with the generals of Gustavus Adolphus, king of Sweden, which was concluded in 1617, and in the following year a truce was made with the Poles, who had supported, by force of arms, the prior election of their prince Ladislaus, and had actually ravaged the country as far as Moscow. In 1625, the young czar married Eudocia, the daughter of a poor gentleman of no fortune, but of great beauty and accomplishments. The interval of peace he employed in promoting the internal prosperity of Russia, and formed a commercial connection with the states of the United Provinces. War was renewed with Poland in 1632, but was terminated in about two years, and from this period the czar preserved his country in a state of tranquillity, respected by neighbouring sovereigns for his equity and good faith, and greatly beloved by his subjects, on account of the mildness and beneficence of his government. He died in 1645, in the thirty-third year of his reign, leaving his crown to his son Alexis. Coxe's Travels.

Michael Cerularius, patriarch of Constantinople, was raised to that dignity in the year 1043. He was a person of vast ambition, and a determined enemy to the church of Rome and the papal claims, and in 1053 he revived the famous contest between the Greek and Latin churches, which had been suspended for a considerable time. He pleaded in his justification a sacred regard to truth and the interests of religion, but the true and genuine causes were the arrogance and ambition of the Grecian patriarch and Roman pontiff. Among the measures to which they mutually had recourse, in order to sap the foundations of each other's authority and influence with the people, were accusations of holding corrupt doctrines. Cerularius struck the first blow, by a letter written in his own name, and in the name of Leo, bishop of Acrida, in which he publicly accused the Latins of various errors. To this letter pope Leo IX. wrote a very imperious reply; assembled a council at Rome, and excommunicated the Greek churches. Bitter and very violent measures succeeded on both sides till the year 1057, when a struggle took place between Stratioticus and Isaac Comnenus for the imperial crown: the patriarch embraced the interests of the latter, and was a chief instrument in raising him to that dignity. In the following year, the emperor being compelled by the exhausted state of the public treasury to impose heavy taxes upon the people, drew from the monasteries a part of their great wealth, with which they had been enriched by his predecessors. This the patriarch resented, and threatened to pull him from the throne to which he had raised him, unless he restored what he had taken from the religious houses. The emperor, without hesitation, arrested, deposed, and banished the patriarch, and in a state of exile he soon died. Some of this patriarch's letters remain, and are referred to by Cave, Dupin, and Mosheim.

Michael, *St.*, in *Geography*, a town of Italy, in the duchy of Mantua, on the Tartaro; 20 miles E. of Mantua.—Also, a town of Italy; 12 miles S.W. of Mantua.—Also, a small island in the English channel, off East Looe, in Cornwall. N. lat. 50° 18'. W. long 4° 32'.—Also, a town of the duchy of Holstein; 6 miles S. of Meldorp.—Also, a town of England, in the county of Cornwall, which, though a small place without a market, sends two members to parliament; 8 miles N.E. of Truro, and 249 W.S.W. of London. N. lat. 52° 22'. W. long. 4° 52'.—Also, a town of Canada, in the river St. Lawrence; 15 miles N.E. of Quebec.—Also, a river of Maryland, which runs into the Chesapeak, N. lat. 38° 50'. W. long. 76° 22'.—Also, a town of Sweden, in the province of Savolax; 10 miles N.N.E. of Christiana.—Also, a town of America, in the state of Maryland, and county of Talbot; 21 miles S.E. of Annapolis.—Also, a town on the S. peninsula of St. Domingo island, called "Fond des Nagra;" 10 leagues N.E. of St. Louis.—Also, an island in the Atlantic, called "San Miguel," the largest of the Azores, discovered by Gonsalvo Velho Cabral in the year 1444. It is about sixty miles in circumference, and has several towns and villages, which carry on a great trade in corn, wine, and cattle, though none of its harbours are good or safe. Its chief towns are Punta del Gada, and Villa Franca. The former is rendered important by its commerce, by its strong castle, in which the Portuguese keep a garrison, and by its being the residence of the primate of the Azores. The number of inhabitants in this island is variously estimated, from 25,000 to 50,000. The town of Punta del Gada is situated in N. lat. 37° 47'. W. long. 25° 42'.

Michael, *St.*, *in Lungau*, a town of the archbishopric of Salzburg; 14 miles S.S.E. of Radstadt.

Michael's *Bay*, *St.*, a bay on the W. coast of the island of Curaçoa.—Also, a bay of Nova Scotia, on the W. coast of the bay of Fundy.—Also, a bay on the E. coast of Labrador. N. lat. 52° 55'. W. long. 55° 40'.

Michael's *Point*, *St.*, a cape on the N.W. coast of Prince's island, in the Atlantic. N. lat. 1° 55'. E. long. 7° 1'.

Michael, *St.*, *Gulf of*, a bay on the coast of South America, in the S.E. part of the gulf of Panama, formed by the mouths of the rivers Congo, Santa Maria, and some others. In it are several islands, which shelter good ridings for ships, and the gulf is sufficiently capacious for a large fleet. The sides are surrounded with mangroves, growing in wet and swampy land.

Michael, *Order of St.*, in *Heraldry*, was instituted by Lewis XI., king of France, in the year 1469, but declined under the reigns of Charles IX. and Henry III. In the year 1661, Lewis XIV. regulated this order, and lessened the number of knights; thus restoring its reputation, so that it rose into high esteem in France. The mantle of the order was of white damask, bordered all round with embroidery in gold and colours, representing the collar of the order, and lined with ermine; the chaperon was of crimson velvet, embroidered like the mantle, under which the knights wear a short coat of crimson velvet. The badge of the order

der is a medallion of gold, representing St. Michael trampling on a dragon, enamelled in proper colours, and worn pendent to a collar, composed of escallop-shells, and chains of gold interwoven like knots. The knights usually wear this badge pendent to a broad black watered ribbon.

MICHAEL, *Order of the Wing of St.*, an order in Portugal, instituted in 1172 by Alphonso, king of Portugal, in commemoration of a signal victory which he gained over Albarac, king of Seville, in consequence, as he imagined, of his having ardently invoked the aid of St. Michael the archangel. The habit of the order was of white silk, on the left breast of which was embroidered a wing purple, within a circle of rays gold. The badge was a cross fleury, fitchy gules, cantoned in base with two fleurs-de-lis; over the cross, on an escroll, this motto, "QUIS UT DEUS."

MICHAELIS, JOHN DAVID, in *Biography*, a celebrated biblical critic, and professor of divinity and the Oriental languages, was born at Halle, in Lower Saxony, in the year 1717. He received a private education, but the Greek language made no part of it till within half a year of its completion, a circumstance which he never ceased to regret. In 1729 he was sent to the public school of the orphan-house, and at the same time he occasionally attended his father's lectures on the Hebrew language. Here he received lessons in divinity from Baumgærtner, but the chief benefit which he received from that professor was in the philosophical course. During the latter part of his time at school, he acquired a great facility in speaking Latin, and in thinking systematically, from the practice of disputation, in which one of the masters frequently exercised him. By his Latin master he was taught to write Latin verses, but as he advanced in life he renounced that study, considering it to be a pedantic misemployment of time. In the year 1733, Michaelis entered into the university of his native place, in order to qualify himself either for the clerical profession, or for the chair of oriental literature, in which his father hoped to see him one day his successor. Here he applied himself with all diligence to the study of mathematics, metaphysics, theology, and the oriental languages. He also prepared himself for pulpit services, and preached with great approbation at Halle and other places. In the year 1739 he took a degree in philosophy, and about the same time he was the subject of a temporary melancholy, which threatened to prove a serious injury to his health, and which was owing to religious impressions, originating in certain misconceptions of some of the scriptural precepts, to which he affixed literal interpretations. Upon his recovery, he was appointed assistant lecturer under his father, having shewn how well qualified he was for that situation, by publishing a small treatise, "De Antiquitate Punctorum Vocalium." In 1741 he left his own country with a view of visiting England, and passing through Holland, became acquainted with the celebrated Schultens, from whom he received many marks of the most friendly attention. Upon his arrival in England, he engaged to officiate for the German chaplain to the court, who was at that time in an infirm state of health, and continued to preach at the palace-chapel nearly a year and a half. During this period he visited the university of Oxford, greatly increased his knowledge of the oriental languages, and formed an intimacy with some of the first literary characters of that age, particularly with Dr. Lowth, afterwards bishop of London, on some of whose lectures "De Sacra Poesi Hebræorum" he attended. Upon the return of Michaelis to Halle, he resumed his labours in the professional chair, as assistant to his father, and delivered lectures on the historical books of the Old Testament, the Syriac and Chaldee languages, and also upon natural history, and the Roman classics; by the exercise of his talents on these subjects he maintained and increased the fame which he had already acquired, but without having the prospect of any immediate good establishment. He therefore resolved to quit Halle, and in 1745 he went to Gottingen, in the capacity of private tutor. In the following year he was made professor extraordinary of philosophy in the university of Gottingen, and, in 1750, professor in ordinary in the same faculty. In 1751 he was appointed secretary to the newly instituted Royal Society of Gottingen, of which he afterwards became director, and about the same time was made aulic counsellor by the court of Hanover. During the year 1750, he gained the prize in the Royal Academy of Berlin, by a memoir "On the Influence of Opinions on Language, and Language on Opinions." While the seven years' war lasted, in which the university of Gottingen was particularly distinguished, Michaelis met with but little interruption in his studies, being exempted, in common with the other professors, from military employment; and when the new regulations introduced by the French in the year 1760, deprived them of that privilege, by the command of marshal Broglio, it was particularly extended to M. Michaelis. For this mark of his favour he was indebted to the good offices of his friend Thierry, who was in great esteem with the minister. Soon after this, he obtained from Paris, by means of the marquis de Lostange, the manuscript of Abulfeda's Geography, from which he afterwards edited his account of the Egyptians. From this time that nobleman was Michaelis's firm friend, and had no little share in procuring him the honour of being chosen correspondent of the "Academy of Inscriptions at Paris," in 1764, and of being elected one of the eight foreign members of that institution. In the year 1760, the professor gave great offence to those of the clergy who styled themselves orthodox, by publishing his "Compendium of dogmatic Theology," consisting of doctrinal lectures which he had delivered by special licence from the government. Shortly after this, Michaelis shewed his zeal for the interests of science and literature, by the part which he took in the project of sending a mission of learned men into Egypt and Arabia, for the purpose of obtaining such information concerning the actual state of those countries, as might serve to throw light on geography, natural history, philology, and biblical learning. He first conceived the idea of such a mission, which he communicated by letter to the privy counsellor Bernstorf, who laid it before his sovereign Frederic V. king of Denmark. That sovereign was so well satisfied of the benefits which might result from the undertaking, that he determined to support the expence of it, and he even committed to Michaelis the management of the design, together with the nomination of proper travellers, and the care of drawing up their instructions. Upon the death of Gesner in 1761, Michaelis succeeded in the office of librarian to the Royal Society, which he held about a year, and was then nominated to the place of director, with the salary for life of the post, which he then resigned. Two years afterwards he was invited by the king of Prussia to remove to Berlin, but his attachment to Gottingen led him to decline the advantages which were held out to him as resulting from the change. In 1766 he was visited at Gottingen by sir John Pringle, whom he had known in England, and Dr. Franklin. With the first he afterwards corresponded on the subject of the leprosy, spoken of in the books of Moses, and on that of Daniel's prophecy of the seventy weeks. The latter subject was discussed in the letters which passed between them during the year 1771, and was particularly examined by the professor. This correspondence was printed by sir John Pringle in 1773, under the title of "Joan. Dav. Michaelis de Epistolæ, &c. LXX. Hebdomalibus

domalibus Danielis, ad D. Joan Pringle, Baronettum; primo privatim missæ, nunc vero utriusque Consensu publice editæ." In the year 1770, some differences having arisen between Michaelis and his colleagues in the Royal Society, he resigned his directorship. In 1775 his well-established reputation had so far removed the prejudices which had formerly been conceived against him in Sweden, that the count Höpkin, who some years before had prohibited the use of his writings at Upsal, now prevailed upon the king to confer upon him the order of the Polar star. He was accordingly decorated with the ensignia of that order, on which occasion he chose as a motto to his arms "libera veritas." In 1782 his health began to decline, which he never completely recovered; in 1786 he was raised to the rank of privy counsellor of justice by the court of Hanover; in the following year the Academy of Inscriptions at Paris elected him a foreign member of that body; and in 1788 he received his last literary honour by being elected a member of the Royal Society of London. He continued his exertions almost to the very close of life, and a few weeks before his death, he shewed a friend several sheets, in MS., of annotations which he had lately written on the New Testament. He died on the 22d of August, 1791, in the seventy-fifth year of his age. He was a man of very extensive and profound erudition, as well as of extraordinary talents, which were not less brilliant than solid, as is evident from the honours which were paid to his merits, and the testimony of his acquaintance and contemporaries. His application and industry were unwearied, and his perseverance in such pursuits as he conceived would prove useful to the world, terminated only with the declension of his powers. His writings are distinguished not only by various and solid learning, but by a profusion of ideas, extent of knowledge, brilliancy of expression, and a frequent vein of pleasantry. In the latter part of his life he was regarded not only as a literary character, but as a man of business, and was employed in affairs of considerable importance by the courts of England, Denmark, and Prussia. His works, as an author, were exceedingly numerous, of which a very long list is given in the General Biography. Of those with which the English scholar has been brought acquainted, the most important is the "Introduction to the New Testament," translated into English from the first edition, and published in 1761, in a quarto volume. In 1788, the fourth edition was published in two volumes quarto. The object of this work, which is purely critical and historical, is to explain the Greek testament, with the same impartiality, and the same unbiassed love of truth, with which a critic in profane literature would examine the writings of Homer, Virgil, &c. The first volume contains an examination of the authenticity, inspiration, and language of the New Testament. The second volume contains a particular introduction to each individual book of the New Testament. An English translation of it has been published by the Rev. Herbert Marsh, in six volumes, royal octavo. Gent. Magazine, March 1792. See also the prefaces by Mr. Marsh.

Michaelis, John-Henry, a learned German divine and orientalist, the son of a citizen of Elrich, was born at Kettenburg, in the county of Hohenstein, in the year 1668. He was intended for trade, but discovering a stronger inclination for study than business, he was allowed to follow the bias of his mind, and obtained admission into the school of St. Martin in the city of Brunswick. Here he was appointed to instruct some of the younger scholars, in which employment he acquitted himself greatly to the satisfaction of the rector of the school. After this he was entered of the university of Leipsic, where he went through courses of philosophy and divinity, and also studied the oriental languages and rabbinical Hebrew. In 1694 he quitted Leipsic for the university of Halle, where he taught the Greek, Hebrew, and Chaldee with great reputation. Here he published, with the assistance of professor Francke, a work entitled "Conamina brevioris Manuductionis ad Doctrinam de Accentibus Hebræorum Prosaicis." In 1696 he published another piece, entitled "Epicrisis philologica de reverendi Michaelis Beckii, Ulmensis, Disquisitionibus philologicis, cum responsionibus ad Examen XIV. Dictor. Gen." He was now thoroughly conversant, not only with the Greek, Hebrew, and Chaldee, but likewise with the Syriac, Samaritan, Arabic, and rabbinical Hebrew, and having formed an acquaintance with Job Ludolf, he accompanied him to Frankfort, for the purpose of learning the Ethiopic language under his instructions. In 1699, he succeeded Francke in the Greek professorship at Halle, and in 1707 was made keeper of the university library. He was afterwards nominated professor of divinity in ordinary, and admitted to the degree of D.D. In 1732 he was made senior of the faculty of divinity, and inspector of the theological seminary. He died in 1738, at about the age of seventy. He was author of many works besides those already mentioned, the titles of which are enumerated in Moreri.

MICHAELMAS, the feast of St. Michael the archangel, held on the 29th of September.

Michaelmas *Island*, in *Geography*, a small island at the entrance of king George III.d's Sound, on the S.W. coast of New Holland; 4 miles N.N.E. of Bald Head.

MICHAILA, St., a town of Russia, in the government of Revel; 36 miles S. of Revel.

MICHAILOV, a town of Russia, in the government of Riazan; 24 miles S.S.W. of Riazan. N. lat. 54° 20'. E. long. 38° 38'.

MICHALOWKA, a town of Poland, in Volhynia; 52 miles N. of Zytomiers.

MICHAUT, Pierre, in *Biography*, secretary to the count de Charolois, son of the duke of Burgundy, in 1466, was author of the poem, entitled "Doctrinal de la Cour, ou Danse des Aveugle;" Instructions for the Court, or Blind-man's-buff. From a beautiful copy of this satirical poem, finely illuminated, M. Laborde has given representations of all the musical instruments used in France during the 15th century in the hands of the performers. Essai sur la Mus.

MICHAUXIA, in *Botany*, named by M. L'Heritier, in one of his monographs, in honour of his friend Andrew Michaux, botanist to the late king of France, Louis XVI., and well known by his botanical expeditions to Syria (where he gathered this plant), Persia, North America, and New Holland. The *Flora Boreali-Americana*, often quoted by us, the fruit of his six years' labours in America, was published by his son. We have already offered some remarks on the name of the present genus. (See Medium.) As to its botanical stability, none who consider the variety of shapes in the corollas of reputed *Campanulæ*, can feel quite sure on the subject; but the author of this genus had contemplated the question with singular attention, and with all his wonted sagacity. He declares *Michauxia* to differ from *Campanula*, as *Chlora* from *Gentiana*, the number of the parts being as eight to five, and the corolla that of a *Phyteuma*, but in eight divisions. It is at least a good artificial genus, and now generally adopted, except that Jussieu adheres to one of its ancient names. (See Mindium.) L'Herit. Monogr. 3. Schreb. 840. Willd. Sp. Pl. v. 2. 342. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 2. 353. Lamarck Dict. v. 4. 134. Illustr. t. 295. (Mindium; Juss. 164.)—Class and

and order, *Octandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, in sixteen lanceolate unequal segments, every other one reversed. *Cor.* of one petal, wheel-shaped, much larger than the calyx, in eight very deep, widely spreading, linear-lanceolate, equal segments, revolute at their points. Nectary of eight valves, bearing the stamens. *Stam.* Filaments eight, awl-shaped, permanent; anthers vertical, linear, very long, pressed close to the style. *Pist.* Germen inferior, turbinate; style columnar, permanent; stigma in eight awl-shaped, revolute segments. *Peric.* Capsule turbinate, abrupt, of eight angular cells, without valves, opening by pores at the base. *Seeds* very numerous, oblong, small, affixed to the proper receptacle of each cell, which unites with the central column.

Eff. Ch. Calyx in sixteen deep segments, alternately reflexed. Corolla in eight deep segments. Nectary of eight valves, bearing the stamens. Capsule of eight cells, opening by pores at the base. Seeds numerous.

Obs. It must be allowed that the number of cells in the fruit being equal to that of the parts of the flower, is very different from *Campanula* and *Phyteuma*, and also that there is no botanical analogy between eight and five or three; so that as far as number can be allowed to guide us, no genus can be better defined.

1. M. *campanuloides*. Rough-leaved Michauxia. L'Herit. Monogr. t. 1, 2. Curt. Mag. t. 219. (Μηδιον; Diosc. book 4. chap. 18. Medium Dioscoridis, or Mindium Rhazis; Rauwolf. It. 284. f. 284. Dalech. Hist. append. 33. Bauh. Hist. v. 2. 805. Campanula peregrina maxima, laciniatis foliis; Moris. sect. 5. t. 3. f. 31.)—Gathered by Rauwolf in Syria, near Tripoli; and by Michaux, above 200 years afterwards, in the same country. Labillardiere is also said to have found it on mount Lebanon. It was raised from seed at Paris; and was communicated to Kew garden by L'Heritier in 1787, but being a greenhouse biennial plant, and rarely ripening seeds in England, is now not to be met with. The *root* is spindle-shaped, whitish, milky, like the rest of the plant. *Stem* from two to six feet high, erect, round, leafy, rough, more or less branched, many-flowered. *Leaves* scattered, lanceolate, acute, jagged, very rough, wrinkled, dark green, sessile, clasping the stem; the lower ones stalked; the radical ones heart-shaped, soon disappearing. *Flowers* ranged along the sides, and solitary at the ends of the branches, sessile, drooping, two inches in diameter, very handsome and singular, not unaptly compared by Curtis to some distant resemblance of a Passion-flower. *Corolla* white, with a tinge of purple at the outside. *Stamens* and *style* green, the upper half of the latter loaded with pollen, lodged by the *anthers* among the hairs which invest it, before they retire and curl themselves together.

L'Heritier's two plates, of this plant and its fructification, are the finest possible, scarcely wanting the assistance of colour to give a complete idea of the objects, and even vieing, in that respect, with the prints of the Houghton Van Huysums. The rude cuts of Rauwolf, Daclechamp, and Bauhin are expressive enough. Morison's engraving, copied and perverted as usual, from them, is very bad. Curtis's plate is necessarily a fragment, but faithful. Tournefort and Linnæus were unaccountably deceived concerning this fine plant. The former confounded it with his own *Campanula foliis profundè incisis, fructu duro;* Tourn. Cor. 3, which is *C. lyrata;* Lamarck Dict. v. 1. 588. Hence Lamarck was led into the same error, which he corrected in his v. 4. 134, as above quoted; and hence Mr. Salisbury, in his Prodromus 127, calls our *Michauxia, Campanula lyræfolia*, citing Lamarck by mistake, and asserting that its fruit is "exactly that of a *Campanula*." Linnæus confounded our plant with *C. laciniata*, Sp. Pl. 237, figured in Tournefort's Voyage, v. 1. t. 99, than which few things, at all akin, can be more distinct. He also, by the specific name of *Medium*, applied to another kind of *Campanula*, very common in gardens, seemed to consider that as the μηδιον of Dioscorides, which we apprehend to be no less a mistake. Dr. Sibthorp suspected *C. laciniata* might be the true μηδιον, being probably unacquainted with the *Michauxia*. The latter surely answers best to the original description, such as it is, of which we here subjoin a translation. "Medium grows in shady stony situations. Its leaves are like succory (σερις). Stem three cubits high. Flowers purple, large, and circular. Fruit (or seed) small, like that of *Cnicus*. Root a span long, as thick as a walking-stick." The colour of the flowers probably varies, from different shades of purple, to white.

Michauxia, in *Gardening*, comprehends a plant of the herbaceous flowering, exotic kind, of which the species cultivated is the rough-leaved michauxia (M. campanuloides.)

Method of Culture.—It may be raised from seed procured from its native situation, and sown in the early spring season in pots, and plunged in a hot-bed, or simply on a moderate hot-bed. When the plants have attained a little growth, they should be removed into separate pots, and be replunged in the hot-bed. This must afterwards be managed as tender green-house plants.

Plants of this sort afford variety in collections of this nature.

MICHAW, in *Geography*, a town of Prussia, in Pomerelia; 22 miles W.N.W. of Dantzic.

MICHEL, St., a small island in the gulf of Venice, near Venice, where the Protestants, who trade thither, have purchased ground on which to build a church.—Also, a town of Italy, in the Veronese; 14 miles N.W. of Verona.—Also, a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of St. Jean de Maurienne; 7 miles S.S.E. of St. Jean. The place contains 1450, and the canton 6244 inhabitants, on a territory of $342\frac{1}{2}$ kiliometres, in 8 communes.

Michel *di Capa, St.*, a town of Peru, in the jurisdiction of Arica, on the borders of a large forest of pimento, which is said to produce annually 300,000lbs. weight of that spice.

Michel-*Gemote*, in *History*. See Parliament.

Michel-*Synoth*. See Parliament.

MICHELAU, in *Geography*, a town of Prussia, in the territory of Culm; 36 miles E. of Culm.—Also, a town of Silesia, in the principality of Brieg; 8 miles S.S.E. of Brieg. N. lat. 50° 46'. E. long. 17° 35'.

MICHELBACH, a town of Germany, in the county of Schwarzenburg; 20 miles W. of Anspach.

MICHELI Romano, in *Biography*, a disciple of Soriano, and a famous canonist, who flourished at the latter end of the 16th century, and beginning of the next; author of a very curious and scarce work, published at Venice, 1615, entitled "Musica vaga et artificiosa continente motetti con oblighi, e canoni diversi, tanto per quelli che vorrano professare d'intendere diversi studii della Musica," folio; or, Artful and curious Music, as well for those who receive delight from the performance of it, as for others who make music their peculiar study. Hist. vol. iii. p. 519.

Micheli, James-Bartholomew, an able mathematician, was born of an ancient family at Geneva, in 1692. He entered into the French military service, and became a captain. In 1738, he retired to his native country, where he applied chiefly to mathematical and philosophical studies. He constructed a number of charts, invented a new thermometer,

mometer, and composed several memoirs, printed at Basle. These are on meteorology and the temperature of the globe; light; the comet of 1680; the universal deluge; &c. He surveyed the Glaciers of Switzerland, of which he took several views, which have been engraved. In the troubles which agitated his country he was a sharer, and was imprisoned a long time by order of the government of Berne. He died in 1766.

MICHELI, PETER ANTHONY, an Italian botanist of great celebrity, particularly in what is now called the cryptogamic department, was born at Florence, December 11, 1679. His parents were indigent, and took but little care of his education. He is said, nevertheless, to have been destined to the occupation of a bookseller, but an insatiable thirst after natural knowledge over-ruled all other objects. Content in the humblest poverty, he resigned himself to his favourite pursuit, trusting to that, even for his means of livelihood. Nor was he disappointed. His good character, and distinguished ardour, soon procured him the notice and favour of the marquis Cosmo da Castiglione, in whose family a taste for Botany has been almost hereditary, and for whom Micheli in his early youth made a collection of Umbelliferous plants, which even then proved his accuracy and discernment. This gentleman introduced him to the celebrated count LAWRENCE MAGALOTTI, (see that article,) by whom he was presented to his sovereign, the grand duke Cosmo III. The *Institutiones Rei Herbariæ* of Tournefort had just appeared at Paris; and the first pledge of the grand duke's favour, was a present of that book, which to Micheli, who had hitherto found the want of some systematic guide, was a most important and welcome acquisition. He speedily adopted the tone of his leader, with respect to generic distinctions and definitions, and improved upon him in a more frequent adaptation of original specific ones.

In the autumn of 1706, the care of the public garden at Florence, founded by Cosmo I., was confided to Micheli, he being appointed botanist to the grand duke. He was commissioned to travel, not only in Italy, but in various distant countries, to collect plants, and to establish a correspondence, for the benefit of his trust. By the co-operation of his friends Franchi and Gualtieri, the garden was enriched from the then more flourishing one at Pisa; and a Botanical Society was instituted at Florence in 1717, which greatly promoted the interests of the science. In the summer of that year, the great William Sherard, returning from Smyrna to England, visited Florence in his way, and formed a friendship with Micheli, that continued till his own decease in 1728. A frequent correspondence, and interchange of specimens, took place between them, as amply appears by the collections preserved at Oxford, and by the writings of Micheli.

The subject of our memoir continued his scientific studies, as well as his bodily exertions in frequent journies. The fruit of the former was the publication of his great work, entitled *Nova Plantarum Genera*, a folio of 234 pages and 108 plates, in 1729. The result of his journies proved but too soon disastrous. He spent near three months, from the 4th of September to the 30th of November 1736, in an excursion to the north of Italy, visiting the famous mount Baldus, and the Venetian isles; but he caught a pleurisy, from the consequences of which he never recovered, dying at Florence, January 2, 1737, new style, in the 58th year of his age. He was buried in the church of Santa Croce, amongst the ashes of some of the greatest men of his country, and of the civilized world, where a neat marble tablet was erected to his memory by his associates. The simple and elegant inscription was probably composed by his learned friend Antony Cocchi, to whom he always confided the revision of his Latin works, before publication, and who delivered an Italian oration in his praise, in the council chamber of the Old Palace, August 7, 1737, which was soon after published. The epitaph is as follows.

PETRUS ANTONIUS MICHELIUS
vixit annos LVII dies XXII in tenui re
beatus omnis historiæ naturalis
peritissimus magnorum etruriæ
ducum herbarius inventis et scriptis
ubique notus ac propter sapientiam
suavitatem pudorem optimis
quibusque ætatis suæ egregie carus
obiit IV nonas Januarias MDCCXXXVII
amici ære conlato titulum posuere.

It does not appear that Micheli was ever married. He is described by his contemporaries as a man of the most pleasing, modest, and liberal manners, no less ready to communicate, than eager to acquire, knowledge. His bodily constitution was good; his health uninterrupted; till his last illness, which was of so decided a nature, that he placidly yielded to his fate, not only with the Catholic ceremonies, but with the feelings of a Christian. His friend Cocchi informs us, that "he was endued with a clear and concise natural eloquence; and although the poverty of his parents deprived him of the advantages of a learned education, he had, by his own application, acquired, with wonderful felicity, a knowledge of Latin."—"The writings of the most eminent botanists were so familiar to him, that he had learned to express his ideas in Latin, by no means amiss, be having a very quick perception as to any barbarous expressions."

We are anxious to collect every particular of the life and character of the author of such a book as the *Nova Plantarum Genera;* a work much more extensive in its compass than the *Historia Muscorum* of Dillenius, superior in physiological merit, as well as in technical style of definition, though deficient in historical and critical disquisition, as well as in description. It is to be lamented that Micheli fell so much into the dry catalogue style of Tournefort, though he has greatly improved upon his model; because they have neither of them attained any thing like the technical synoptical terseness and precision of subsequent times. The great merit of Micheli consists in his accurate scientific illustration of some of the most difficult tribes of plants, which Tournefort had left unattempted. The order of the *Calamariæ*, and particularly the difficult genus *Carex*, first assumed an intelligible form under his hands. The seeds of the latter, and their coverings, were first resorted to, with the happiest effect, for specific discrimination. (See CAREX.) A vast number of species of the hitherto neglected genus *Lichen* were ascertained and well delineated. It is with great injustice that Dillenius, whose figures of the crustaceous and imbricated Lichens are the meanest part of his work, charges Micheli with erring on the side of luxuriance in his representations. He had indeed more favourable subjects of investigation, owing to the climate in which he lived; for in Italy the plants in question are found vastly more luxuriant and prolific than in the north of Europe; and we can aver that the figures and descriptions of Micheli are as faithful as those of Dillenius himself; they cannot be more so. (See DILLENIUS.) The parts of the flowers of Mosses, properly so called, were first displayed in the work of Micheli, though he did not understand their real uses. (See MUSCI.) He was equally successful in the collateral families, now termed *Hepaticæ*, founding the genera of *Blasia*, *Marsilea*, *Jungermannia*,

nia, Sphærocarpus, Anthoceros, Targionia, &c. In the natural order of *Fungi,* till then almoſt totally neglected, he diſplayed great accuracy and originality, and gave the firſt ſynoptical diſtribution of thoſe difficult vegetables, by which his followers have profited. Many genera of the more perfect or phænogamic plants are alſo illuſtrated or founded in this work of Micheli; but neither their diſtinctions nor their nomenclature is, in general, ſo good as the former. In ſpecific diſtinction, he was too prone to raiſe varieties to the importance of ſpecies, of which his numerous kinds of *Trifoliaſtrum* are inſtances.

Our author had extended his ſtudies to the Submarine plants, or Sea-weeds, and had numerous plates engraved, for publication in a ſecond volume, had his life been prolonged. Of theſe plates a ſet of impreſſions, procured by the late lord Bute, was bought at his lordſhip's ſale, by the Rt. Hon. ſir Joſeph Banks, and is, through his liberality, acceſſible to all. Another ſet, now in the Linnæan library, was given to its preſent poſſeſſor by Dr. Targioni Tozzetti of Florence, whoſe father purchaſed all Micheli's remains, among which are valuable manuſcripts of various kinds; eſpecially the deſcriptions of theſe plates. There are likewiſe ſome rude drawings of *Orchideæ,* the work we believe of Micheli himſelf. His pencil however was not ſufficiently excellent to enable him to be in general his own draughtſman; ſtill leſs could he, like Dillenius, engrave the plates he publiſhed. In ſtudying the above-mentioned marine productions, it is not wonderful, nor reprehenſible, that he then confounded corals and corallines with plants, and made a genus out of the preſent *Sertularia,* which he called *Dillenia.*

Micheli had prepared an alphabetical catalogue of the plants in the garden, of which he had the ſuperintendance. This was publiſhed in 1748, in folio, with ſeven botanical plates, beſides a plan of the garden, under the title of *Catalogus Plantarum Horti Cæſarei Florentini;* for the race of the Medici, and the golden age of Florence, had now paſſed away. Their imperial ſucceſſors, however, patronized ſcience, and the volume in queſtion is dedicated to the emperor Francis I., by its editor John Targioni Tozzetti, who has prefixed an excellent hiſtorical preface of his own; as well as a more oratorical Italian diſcourſe, upon natural hiſtory, by the before-mentioned Antony Cocchi.

The ſtudies of Micheli were extended to foſſils, and petrifactions, of both which numerous ſpecimens remain in his muſeum: but he publiſhed nothing reſpecting them. An account of three of his botanical tours in Italy is ſaid, by Haller, to be extant, in the ſixth volume of Travels publiſhed by Targioni Tozzetti; but of this publication we have ſeen only the firſt volume. We ought alſo to mention his firſt publication in 1723, an octavo pamphlet on *Orobanche,* in Italian, chiefly with a view to its extirpation, as a noxious weed. This is ſaid to be beſt accompliſhed by eradicating the beans or other plants, on which the *Orobanche* may be perceived to have fixed itſelf, in the month of April; by which proceedure, being an annual herb, its propagation is cut off. Works of Micheli. Smith's Tour on the Continent. Cocchi Elogio di P. A. Micheli. Haller Bibl. Bot. S.

MICHELIA, in *Botany,* ſo denominated by Linnæus, in memory of the great Florentine botaniſt Micheli. (See the laſt article.) Linn. Gen. 278. Schreb. 374. Willd. Sp. Pl. v. 2. 1260. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 2. v. 3. 332. Juſſ. 280. Lamarck Dict. v. 1. 690. Illuſtr. t. 493. Gærtn. t. 137?—Claſs and order, *Polyandria Polygynia.* Nat. Ord. *Coadunatæ,* Linn. *Magnolia,* Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, coriaceous, ſplitting longitudinally, falling off as the flower expands. *Cor.* Petals numerous, lanceolate, in ſeveral rows; the outer ones largeſt. *Stam.* Filaments numerous, ſhort, linear, inſerted into the common receptacle of the piſtils below the germens; anthers terminal, linear, of two cells, burſting longitudinally at the inner ſide, ſurmounted by a bluntiſh point. *Piſt.* Germens numerous, imbricated in an oblong ſpike; ſtyles none; ſtigmas reflexed, obtuſe. *Peric.* Berries equal in number to the germens, coriaceous, globoſe, of one cell, diſpoſed in a large cluſter. *Seeds* from four to eight, angular on one ſide, convex on the other.

Eſſ. Ch. Calyx of one leaf, coriaceous, immediately deciduous. Petals numerous, in ſeveral rows. Berries numerous, with ſeveral ſeeds.

1. M. *Champaca.* Sweet Yellow Michelia, or Champawk. Linn. Sp. Pl. 756. (Champacam; Rheede Hort. Mal. v. 1. 31. t. 19. Sampacca; Rumph. Amboyn. v. 2. 199. t. 67. Champe; Bauh. Pin. 470.)—Leaves lanceolate, ſomewhat ovate. Calyx externally ſilky.—Native of Malabar, in ſandy places, flowering twice in the year, but not bearing fruit till it is very old. *Rheede.* Commonly cultivated throughout India, eſpecially in the Malay countries, but never found wild. *Rumphius.* Cultivated at Orford, Lancaſhire, by John Blackburne, eſq. in 1779. *Hort. Kew.* This *tree* is celebrated for the exquiſite perfume of its *flowers,* of which moſt Europeans, who have been in India, ſpeak with rapture, though ſome find it too powerful. The natives adorn their heads with theſe *flowers,* both for the ſake of the perfume, and for the elegant contraſt of their rich orange colour, with their own black hair. The *tree* is of a moderate ſize; the bark of its *root* red, bitter, and very acrid, according to Rheede. *Branches* round, alternate, ſmooth, leafy, chiefly at their extremities. *Leaves* alternate, ſtalked, a ſpan long, ovato-lanceolate, entire, taper-pointed; a little tapering at the baſe; ſomewhat ſilky when young, but finally ſmooth, or nearly ſo; rather glaucous beneath; furniſhed with a midrib, and many tranſverſe, oblique, parallel veins, connected by innumerable fine reticulations. *Footſtalks* an inch long, minutely hairy, channelled above. *Stipulas* none. *Flowers* not unlike a double narciſſus, axillary, ſolitary, on ſimple, ſhort, very thick ſtalks. *Petals* elliptic-lanceolate, the colour of the yolk of an egg, the outermoſt about an inch and a half long. *Calyx* ovate, ſcarcely an inch long, finely ſilky, ſplitting down one ſide, and ſeparating from the baſe, before the flower can expand. *Fruit* reſembling a large bunch of grapes, of a pale yellowiſh-white when ripe, very acrid to the taſte, and unpleaſant to the ſmell, according to Rheede. The *ſeeds* are from four to eight, angular from mutual preſſure, the ſize of ſmall peas.

Such is the real *M. Champaca,* of which we have obtained fine ſpecimens from Madras, and have conſequently been enabled to correct the deſcription of the *calyx,* which authors have greatly miſunderſtood. Rheede and Rumphius miſled Linnæus to ſuppoſe there was none; for he originally deſcribed this plant from books only. Afterwards procuring, by the name of *Tſiampacca lalac,* a ſpecimen of our *Magnolia pumila,* (ſee MAGNOLIA, n. 7, where it will appear how much ſuch exotic names are liable to corruption,) he miſtook this for *Michelia Champaca,* and thence altered the character of the genus, in his *Mantiſſa* 140, attributing to it a calyx of three oblong petal-like leaves. How Lamarck diſcovered and figured a ſhort permanent three-leaved calyx we know not. Linnæus had in his herbarium the real *Champaca,* inſcribed *Tſiampacca coenang,* as far as we can decypher the ſcrawl, which he marked *M. Tſiampacca.*

Tsiampacca. Our Indian botanical friends assure us this is only the same name spelt differently, and therefore some contend for the existence of only one species of *Michelia.* We shall endeavour to establish a second.

2. M. *sylvestris.* Wild Whitish Michelia. (M. Tsiampacca; Linn. Mant. 78. M. euonymoides; Burm. Ind. 124. Sampacca sylvestris; Rumph. Amb. v. 2. 202. t. 68.)—Leaves elliptical. Calyx nearly smooth.—Linnæus received this from India by the name of *Tsiampacca poeti*, or White Champawk, which agrees with the name and synonym in Rumphius. It differs from the former in the broad elliptical shape, and perfect smoothness, of its *leaves.* The *calyx* also is smooth, having merely a very slight silkiness at the tip; the rest being finely granulated. Our specimens shew nothing further, but they agree with all the above synonyms perfectly, except that Burmann has a very erroneous quotation of Sloane, and moreover says the Javanese call this species *Tsiampacca conneng*, which Linnæus, we know not on what authority, applied to the former. We could not retain Burrmann's specific name, because it seems suggested by Sloane's synonym, and is totally irrelative to our plant. *Tsiampacca* and *Champaca* are, as we have said, synonimous and ambiguous. We therefore adopt a name from the manuscripts of Linnæus, which it is pity he altered. Rumphius describes the *M. sylvestris* as a more tall and upright *tree* than the *Champaca*, with larger and broader *leaves*, the breadth of four fingers (exactly as we have them); and he very accurately remarks that they have fewer ribs, or transverse veins. *Flowers* exactly like the former, except that their *petals* are broader, whitish, or straw-coloured, with but a slight degree of odour. When cultivated however they acquire a stronger and more delightful smell, though not equal to the *Champaca.* The *fruit* is much the same, though the *seeds*, which vary from two to seven in number, are scarcely so red. It is very possible that this may, after all, be only the wild state of the *Champaca*, but we have now furnished sufficient materials to prevent any future mistake of either, and we trust the generic character is sufficiently established. Gærtner obtained from Thunberg, as the fruit of *M. Tsiampacca*, what looks most like a *Magnolia*, and we cannot but think, the more it is compared with Rumphius, whose figures, we must always recollect, are diminished, the more it will prove different from his.

If Andrews's tab. 229, *Magnolia fuscata*, (see MAGNOLIA n. 8,) be compared with our description of the *calyx* of *Michelia*, they will be found to agree. The *petals* however are those of a *Magnolia*, and we must still remain in doubt for want of the *fruit* of this elegant shrub. It is curious that Linnæus had a specimen of this *Magnolia*, which he very incautiously marked *Michelia Tsiampacca.* On dissecting a flower, he found the *calyx* of three leaves. Whether this be correct or not, though we have three coloured figures of this plant in our periodical publications, none of them enables us to form even a conjecture, except Andrews, and this but incidentally. We have some suspicion that Loureiro's *Liriodendron Figo* may possibly be the same with *Magnolia fuscata*, but unfortunately his slight mention of the fruit affords no certain information as to its genus. The *calyx* however, being of one leaf, agrees. He says his plant is called at Macao *Fula Figo.* Has this any connection with the *Fulle*, Bauh. Pin. 470?

This fine tribe of plants is so little understood by botanists, and so many errors have attended the history of the *Michelia*, which the Linnæan herbarium alone could explain or remove, that we have been more particular than usual, and still the subject is far from being exhausted. S.

MICHELIA, in *Gardening*, comprehends a plant of the tree or shrub kind, of which the species commonly grown is the champaca, or Indian michelia, (M. champaca.)

Method of Culture.—This is a plant which may be increased by seeds, layers, and cuttings, being managed in the same manner as the more tender green-house plants afterwards.

They afford variety in collections of stove plants.

MICHELPACH, in *Geography*, a town of Austria; 12 miles S.E. of St. Polten.

MICHELSDORF, a town of Bohemia, in the circle of Chrudim; 9 miles N.E. of Leutmischl.

MICHICOUI, a river of America, in the state of Vermont, which runs into lake Champlain. N. lat. 44° 55'. W. long. 72° 56'.

MICHIGAN, the largest lake in the territory of the United States, lies between 41° 8', and 45° 40' N. lat. and between 84° and 87° W. long. Its length is estimated at 260 miles from N. to S., and its circumference at 945 miles; and, according to Mr. Hutchins, it contains 10,368,000 acres. It is navigable for ships of any burden. It communicates with lake Huron at the N.E. part through the straight of Michillimakkinak, which is six miles broad, with a fort of its name on an island at its mouth. In this lake are several kinds of fish, and particularly excellent trout, weighing from twenty to sixty pounds. On the N.W. parts of this lake the waters pass through a narrow strait, and branch out into two bays; that to the northward is called Noquet's bay, and the other to the southward Puans, or Green bay, which forms with the lake an extended peninsula, called cape Townsend, or Vermilion point. About thirty miles S. of Bay de Puans, is lake Winnebago, which communicates with it, and a very short portage interrupts the communication south-westward from Winnebago lake through Fox river, then through Ooisconsin, into the river Missisippi. Chicago river, at the S.W. extremity of lake Michigan, furnishes a communication, interrupted by a still shorter portage, with Illinois river. Lake Michigan receives many small rivers from the W. and E., some of which are 150 and even 250 yards broad at their mouths.

MICHILLIMAKKINAK, called by the Canadians "La Grosse Isle," the name of an island, fort, and village, on the S.W. side of the straits of the same name. The island on which the village and fort stand is very barren, but, as the grand rendezvous of the Indian traders, a considerable traffic is carried on; and its situation will probably render it a place of commercial importance. It is within the line of the United States, and contains 251 inhabitants: distant about 200 miles N.N.W. from Detroit. N. lat. 45° 48' 34". W. long. 84° 30'.

MICHILLIMAKKINAK, *Little*, a river on the N.W. territory of America, which enters the S.E. side of Illinois river, by a mouth fifty yards wide, at which there are between thirty and forty small islands. It runs a N.W. course, and is navigable about ninety miles. On its banks is plenty of good timber, *viz.* red and white cedar, pine, maple, walnut, &c.; and here are also coal-mines.

MICHIPICOTEN, a river which runs into lake Superior, on the N.E. side of the lake. At its mouth it forms a bay of its own name; and on the W. part of the bay is a large island, so called, close to the land. On the E. side of the mouth of the above river, in N. lat. 47° 56', is Michipicoten House, belonging to the Hudson's Bay company.

MICHISCOUI, the Indian and present name of the most northerly river in Vermont. It is navigable seven miles from its mouth.

MICHISCOUI *Tongue*, a long point of land which extends southerly foutherly into lake Champlain from the N.E. corner of Vermont, on the W. fide of the bay of this name, and forms the townfhip of Allburg.

MICHO, the name of a cove or bay of Canada, on the S. coaft of the river St. Lawrence; 218 miles below Quebec. N. lat. 49° 5′. W. long. 66° 30′.

MICHOWITZ, a town of Bohemia, in the circle of Kaurzim; 12 miles W.S.W. of Kaurzim.

MICKELSO, a fmall ifland in the Baltic, E. of Aland. N. lat. 60° 12′. E. long. 20° 5′.—Alfo, a fmall ifland on the E. fide of the gulf of Bothnia. N. lat. 63° 27′. E. long. 21° 19′.

MICKERY, a fmall ifland in the Frith of Forth; 8 miles N.W. of Leith. N. lat. 56° 2′. W. long. 3° 17′.

MICKLE, William Julius, in *Biography*, was born, in 1734, at Langholm, in Dumfriesfhire, Scotland, of which place his father was minifter. After a preparatory education under his father, he was fent to the High-fchool at Edinburgh, where he was continued till he was fixteen years of age, when he went into the counting-houfe of a relation to be initiated in the art of brewing. He remained in this bufinefs a few years; but a tafte for reading and poetry rendered him unfit for the neceffary routine of trade. In 1763, he quitted Edinburgh for London, with a view of foliciting employment in the fea fervice, to which he felt a ftrong inclination. He took in his pocket a poem, entitled "Providence," which he contrived to get introduced to lord Lyttleton, at that period a patron of the mufes, but with refpect to our author it produced nothing but a complimentary correfpondence. Several projects for a fettlement at home and abroad, in a commercial or official fituation, having failed, he at length accepted the humble fituation of corrector to the Clarendon prefs at Oxford. In 1767, he publifhed his poem, entitled "The Concubine," the title of which, after it had gone through three editions, was changed to "Sir Martyn," as the firft title had occafioned fome mifconception of its nature. It was written in the ftyle and manner of Spenfer, and difplays much poetical imagery, with a confiderable facility of verfification. Its object is to expofe the evils and difgraces refulting from illicit love, terminating in concubinage. His name now became known to the public, and a way was prepared for the reception of his moft confiderable performance, which was the tranflation of the "Lufiad" of Camoens. He had, at firft, doubts of the probable fuccefs of fuch a work, and publifhed, as a fpecimen, the firft book; and being encouraged by his friends and the public, he refigned his office at the Clarendon prefs, and took lodgings at a farm-houfe, in order that he might devote his whole attention to the tafk. His tranflation was finifhed in 1775, and publifhed under the title of "The Lufiad, or the Difcovery of India," with an introduction, containing an account of the Portuguefe conquefts in that country, the life of Camoens, a differtation on the Lufiad, &c. &c. This work obtained for him a high rank among the Englifh poets, and it is faid by an able critic, that, "as far as fplendour of diction and melody of verfification can go to eftablifh a poetical character, the name of Mickle has not many fuperiors." No metrical tranflator ever took greater liberties with his original than Mickle; and it is certain that his poem, and that of Camoens, have little more in common than the plan and outline. Their difference confifts not only in the language, but in many circumftances and incidents of the piece. Thus Mickle has painted a ftorm and a naval action in three hundred lines, of which there is not the fmalleft veftige in the original. His fuppreffions are as frequent as his interpolations, of which the reader fhould be apprized, if he go to compare the Portuguefe poem with its Englifh tranflation. His purpofe was to give a poem that might live in the Englifh language, which he has attained. Previoufly to the publication of the Lufiad, he had written a tragedy, entitled the "Siege of Marfeilles," which being offered to Garrick, was refufed as unfit for the ftage. The fame fentence was paffed upon it by Mr. Harris and Sheridan, and he fubmitted, after a time, to their decifion with decent fortitude. In 1779, he went out as fecretary to governor Johnftone, who had been appointed to the command of the Romney man of war. He was left at Lifbon as joint-agent for prizes. Here, on account of the honour that he had done to the chief poet of the country, he received many very many flattering marks of attention, and was admitted into the Royal Academy of Lifbon at its firft opening. While at the Portuguefe capital, he wrote his poem of "Almada-hill, an Epiftle from Lifbon," which by no means fupported the reputation which he had acquired by the Lufiad. In his foreign miffion he had acquired fome property, and on his return he fettled at Wheatley, near Oxford, where he died in 1789, leaving behind him a character for ftrict integrity and honour, intermixed, perhaps, with fome foibles and imperfections.

Mickle *Rooe*, in *Geography*, one of the fmaller Shetland iflands. N. lat. 60° 30′. W. long. 1° 49′.

MICKLEHAM, a village and parifh fituated in the hundred of Copthorn, and county of Surrey, England. The houfes are placed in a vale between Leatherhead and Dorking, and the valley is watered by the river Mole, and claims the attention of the topographer on account of the peculiar and picturefque nature of its fcenery, and the many handfome feats included within its jurifdiction. On the weft of the village rifes a gentle hill, adorned by the handfome manfion of Norbury-park, the property of William Locke, efq. and on the eaft is Mickleham Down, a very fine fheep-pafture, belonging to fir Lucas Pepys, bart. Part of this Down is covered with plantations, which were begun by the late fir Cecil Bifhop, about the year 1763, which ferve both to fhelter and ornament the feat of the proprietor, fituated immediately beneath them. A part of the Roman road, called Stanes-ftreet, can be diftinctly traced not far from the houfe. At fome diftance further, to the fouth-eaft, is an eminence called Boxhill, from the vaft quantity of box trees growing on its fummit and fide. This hill afcends abruptly from the Mole, and commands, from its fummit, a very grand and extenfive profpect. What is remarkable, there is a well on the top of it, the water of which ftands at only fifteen feet from the furface, whereas, on another hill oppofite, it is neceffary to raife the water 430 feet. The Mole, which in its paffage through this parifh forms a very ferpentine current, finks entirely into the ground at different places, which commonly are denominated the Swallows.

The church of Mickleham is a very ancient building, and is rather remarkable in its architecture. It is built of ftone, and confifts of a nave, with a chancel at the eaft end of it, a fmall chapel on the north fide, and a fouth aifle, feparated from the nave by round pillars fupporting femi-circular arches. The eaft window is adorned with handfome tracery works, and on each fide of the chancel are two windows, with lancet-fhaped tops within a round-headed arch, which refts upon round pillars, and is ornamented with a fingle row of fquare billet-work. At the weft end rifes a low fquare tower, ftrengthened by double angular buttreffes, and furmounted by a pyramidal fpire. The font is of folid ftone, the bafon having been hollowed out from it. Here are feveral monuments, but none of them peculiarly interefting. The living is a rectory.

According

According to the parliamentary returns of 1801, the number of inhabitants in the whole parish amounted to 389 persons, of whom 186 were males, and 203 females. The grounds of Norbury-park are finely wooded, and diversified with lofty eminences. The house has long been noted for its pictures and works of art; one room is covered with paintings, by Barrett, and is much admired for its style and execution. It represents the mountain and lake scenery of Westmoreland. See Gilpin's Western Counties, and Manning's History of Surrey, edited by William Bray, esq. F. S. A. fol. vol. ii. 1809.

MICKMACKS, American Indians, who inhabit the country between the Shapody mountains and the gulf of St. Laurence, in Nova Scotia, opposite to St. John's island. These people are said to convey their sentiments by hieroglyphics, marked on the rind of the birch, and on paper, which the Romish missionaries perfectly understand. Many of them reside at the heads of the rivers in King's and Hants counties.

MI CONTRA FA, in *Counterpoint*, was long regarded as a solecism in harmony. The natural diatonic scale consisting of tone, tone, and semitone, as C D *e f*, or *ut, re, mi, fa*; G A ♭ *c*, or *sol, la, mi, fa*; if the 4th *fa*, in the key of C, or C in the key of G, was made sharp, it would be called *tritonus*, or a dissonant series of four whole tones; which, before the ear was accustomed to crude intervals, in the infancy of counterpoint, was so offensive, that it used to be said, *Mi contra fa est diabolus*. Alluding to this in king Lear, act i. sc. 7. there is a passage which has much embarrassed the commentators: "O, these eclipses portend these divisions! *Fa, sol, la, mi.*" Shakspeare, however, shews by the context, that he was well acquainted with the nature of the musical intervals contained in the *tritonus*, or sharp 4th, which, consisting of three tones without the intervention of a semitone, is extremely difficult to sing, and disagreeable to uncultivated ears when sung, if *mi* or *fa* terminate the passage.

The false 5th is only an inversion of the sharp 4th, as B F or F B, which were held in equal horror by our fore-fathers; though at present the chief beauties of melody and harmony are derived from these intervals.

MICOTSI, Moses, in *Biography*, a learned Spanish Jew, who flourished in the 14th century, is chiefly known as author of a work, entitled "Sepher Miseroth Gadol," or "The Great Book of Precepts," which is explanatory of the commandments of the Jewish law, and which was printed at Venice in 1545. It is much applauded by father Simon, who says it is highly deserving of diligent perusal, on account of the great learning and judgment with which the author has treated the subject. Moreri.

MICOYA Bay, in *Geography*, a bay situated on the S.W. coast of Mexico, on the Pacific ocean. N. lat. 10° 18′.

MICRANTHEMUM, in *Botany*, from μικρος, *small*, and ανθος, *a flower*. Michaux Boreal-Amer. v. 1. 10. (Globifera; Gmel. Syst. Nat. Linn. v. 2. 32.)—Class and order, *Diandria Monogynia*. Nat. Ord. *Rotaceæ*, Linn. *Lysimachiæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in four deep, somewhat spatulate segments; the two uppermost rather the smallest. *Cor.* scarcely longer than the calyx, of one petal, nearly bell-shaped; tube very short, smooth within; limb in four deep unequal segments, obsoletely two-lipped, its upper segment smallest. *Stam.* Filaments two, incurved towards each other, with an appendage at the base; anthers of two roundish lobes. *Pist.* Germen superior, almost globular; style short, rather declined; stigma capitate, depressed, oblique. *Peric.* Capsule nearly globular, clothed with the permanent calyx, of one cell and two valves. *Seeds* numerous, ovate, finely striated, sessile upon the central depressed receptacle.

Ess. Ch. Corolla unequally four-cleft. Stamens with an appendage at their base. Capsule of one cell and two valves. Seeds numerous. Calyx inferior, in four deep spatulate permanent segments.

1. M. *orbiculatum*. Michaux, t. 2. (Anonymos umbrosa; Walt. Carolin. 63. Globifera umbrosa; Gmel. n. 1.)—Native of damp shady places, in the woods of Carolina and Georgia, flowering in August. *Michaux*. *Roots* fibrous, annual? *Stems* prostrate, branched, a span long, thread-shaped, leafy, smooth like every other part of the herb. *Leaves* opposite, sessile, nearly orbicular, entire, one-fourth of an inch long, with one rib, and several nearly longitudinal veins. *Flowers* axillary, alternate, solitary, on short capillary simple stalks, not half the length of the leaves, white, the size of a small pin's head.

MICRANTHUS, (from the same derivation as *Micranthemum*,) Wendl. Obs. 39. (see Phaylopsis); Willd. Sp. Pl. v. 3. 342.

MICRELIUS, John, in *Biography*, a very learned German Lutheran divine, was born at Callin, in Pomerania, in the year 1597. He pursued his theological course at Stettin, and became distinguished for his industry and talents. He took his degrees, in succession, with much applause. In 1653, he made a voyage to Sweden, and received many tokens of respect, and testimonies of liberality, from queen Christina. He died in 1658, leaving behind him several works of great learning and research. Among these may be mentioned "Lexicon Philologicum;" "Lexicon Philosophicum;" "Syntagma Historiæ Mundi;" "Syntagma Hist. Ecclesias;" some school books, as "Arithmeticæ, usus Globorum, &c.;" and a vast number of "Theses," "Orations," &c.

MICROCARPÆA, in *Botany*, so named by Mr. Brown, from μικρος, *small*, and καρπος, *fruit*, the capsules of his original species being no larger than a pin's head, and the numerous seeds consequently extremely minute. Brown Prod. Nov. Holl. v. 1. 435.—Class and order, *Diandria Monogynia*. Nat. Ord. *Personatæ*, Linn. *Scrophulariæ*, Juss.

Ess. Ch. Calyx inferior, tubular, five-sided, five-cleft. Corolla two-lipped. Barren stamens none. Capsule of two valves and two cells, with a contrary, and at length loose, partition.

1. M. *muscosa*. Br. (Limosella diandra; Linn. Mant. 252. Willd. Sp. Pl. v. 3. 342. Pæderota minima; Koenig in Retz. Obs. fasc. 5. 10. Willd. Sp. Pl. v. 1. 77.)—Leaves linear-spatulate, about as long as the flower-stalks.—Gathered by the late Dr. I. G. Koenig, in sandy, occasionally inundated, places, at the Cape of Good Hope, as well as at Madras; and by Mr. Brown in the tropical part of New Holland. This diminutive plant grows in dense patches. When examined separately, it will be found very like the European *Limosella aquatica*, though but one-fourth its size; nor can we wonder at Linnæus for having referred it, though diandrous, to the same genus; especially since Krocker has found the *aquatica* to be sometimes diandrous; see Willdenow. Mr. Brown however, finding the corolla irregular and two-lipped, and the capsule of two cells, thought himself justified in establishing the present as a distinct genus; to which we cannot but assent; though it must be observed that the real *limosella* betrays some irregularity of corolla in the incurvation of its two upper segments.—*M. muscosa* has a considerable likeness to *Montia fontana*. The whole *herb* is smooth. *Roots* fibrous, pale, probably annual. *Stem* creeping,

creeping, branched. *Leaves* oppofite, erect, ftalked, fpatulate, narrow, entire; not an inch long, including their footftalks. *Flower-ftalks* axillary, folitary, quadrangular at leaft when dry, fcarcely overtopping the leaves. *Bracteas* none. *Flowers* folitary, erect; their limb pale purplifh. Segments of the *calyx* broad, fhort, and blunt.

2. M. *cochlearifolia.* (Pæderota cochlearifolia; Koenig MSS. Hedyotis maritima; Linn. Suppl. 119. Willd. Sp. Pl. v. 1. 566.)—Leaves obovate, concave. Flowers nearly feffile.—Gathered by Koenig, and by his pupil Rottler, in the Eaft Indies; we believe on the coaft of Coromandel. This has the habit of the firft fpecies, but is of a much larger proportion. *Root* of long fimple fibres, apparently annual. *Stems* numerous, proftrate, varioufly branched and divaricated, four or five inches long, flender, fmooth, leafy. *Leaves* oppofite, on fhort ftalks, obovate, obtufe, entire, fmooth, fomewhat flefhy, rather concave, about half an inch in length, with fome fmaller axillary ones. *Flowers* axillary, oppofite, folitary, on very fhort thick ftalks. *Capfule* nearly globofe, the fize of coriander feed, pale brown, thin and brittle.

Mr. Brown points out the very near affinity of this plant to the former, from which he fays it differs, in having a capfule without valves. This is indeed fo far correct, that the capfule ufually breaks cafually at the fides; but traces of two diftinct valves, each with a narrow partition from its centre, may readily be perceived, and thefe fometimes feparate regularly at the top, in the ufual way, even to the bafe, as we find by examining various fpecimens. This difficulty therefore being removed, we are glad to find a proper place for the plant in queftion, whofe difagreement with HEDYOTIS we have already pointed out; fee the conclufion of that article. Dr. Koenig having made it, like the former, a *Pæderota,* proves its having but two ftamens, he being fo rigid a Linnæan, that he ufually confidered the characters of the artificial claffes as abfolute, the orders having been, in his day, little obferved.

MICROCHLOA, from μικρος, *fmall,* and χλοα, *a grafs.* Brown Prod. Nov. Holl. v. 1. 208.—Clafs and order, *Triandria Digynia.* Nat. Ord. *Gramina.*

Eff. Ch. Spike unilateral, without joints. Calyx fingle-flowered, of two nearly equal, acute, membranous valves. Corolla included, inverfed, of two beardlefs hairy valves. Stigmas feathery.

1. M. *fetacea.* Br. (Rottboellia fetacea; Roxb. Coromand. v. 2. 17. t. 132. Nardus indica; Linn. Suppl. 105. Willd. Sp. Pl. v. 1. 315.)—Native of old walls, on the coaft of Coromandel, and of the tropical region of New Holland. A diminutive annual grafs, with a fibrous *root,* and feveral erect *ftems,* from two to fix inches high, fmooth, round, and leafy. *Leaves* fhort, keeled, channelled, with a fheathing bafe. *Spikes* terminal, long, fimple, very flender, a little incurved, compofed of a fingle rank of imbricated purplifh *flowers,* all directed one way. *Stamens* yellow, two or three. *Styles* purple.

MICROCORYS, from μικρος, *fmall,* and κορυς, *a helmet,* alluding to the fhortnefs of the upper lip of the flower. Brown Prod. Nov. Holl. v. 1. 502.—Clafs and order, *Didynamia Gymnofpermia.* Nat. Ord. *Verticillatæ,* Linn. *Labiatæ,* Juff.

Eff. Ch. Calyx femi-five-cleft. Corolla ringent; its concave upper lip very fhort; middle fegment of the lower lip broadeft. Two upper ftamens included, the fertile lobe of their anthers fmooth, the empty one bearded; two lower with deeply cloven abortive anthers.

A genus of *fhrubs,* found by Mr. R. Brown in the fouth part of New Holland. All the fpecies have entire *leaves,* three in a whorl. *Flowers* axillary, folitary, either white or purple, each with two *bracteas.*

1. M. *virgata.*—Leaves linear, obtufe, fmooth like the calyx. Bracteas deciduous. Stem erect, with thread-fhaped branches.

2. M. *barbata.*—Leaves linear, obtufe, fmooth. Calyx and corolla externally hairy. Bracteas deciduous. Stem diffufe.

3. M. *purpurea.*—Leaves oval-oblong, recurved at the margin; minutely downy on both fides; dotted beneath. Young branches filky. Calyx hoary. Bracteas briftle-fhaped, permanent.

MICROCOS, fo called by John Burmann, Thefaur. Zeyl. 159, who appears to have had in his contemplation the fmallnefs of the berry, or drupa, and therefore the word is to be derived from μικρος, *fmall,* and κοκκος, *a berry,* abbreviated for the fake of harmony. Linn. Gen. 267. Schreb. 356. Willd. Sp. Pl. v. 2. 1168. Gærtn. t. 57.—Clafs and order, *Polyandria Monogynia.* Nat. Ord. *Columniferæ,* Linn. *Tiliaceæ,* Juff.

Gen. Ch. *Cal.* Perianth inferior, of five oblong, bluntifh, fpreading, deciduous leaves. *Cor.* Petals five, linear, equal, emarginate, rather fpreading, various in fize. Nectary none. *Stam.* Filaments numerous, capillary, the length of the calyx, inferted into the bafe of the germen; anthers roundifh. *Pift.* Germen roundifh, fupported by a fhort five-fided column, at whofe top the ftamens are inferted; ftyle cylindrical, fhorter than the ftamens; ftigma bluntifh. *Peric.* Drupa roundifh. *Seed.* Nut turbinate, clothed with long capillary fibres connected with the pulp, of three clofe cells, filled with folitary kernels.

Eff. Ch. Calyx of five leaves. Petals five, without any feparate nectaries. Drupa ftalked, with a hairy nut of three cells.

Linnæus, after having adopted this genus from Burmann, reduced it in his *Syftema Vegetabilium* to *Grewia,* from which Gærtner, who is followed by Schreber and Willdenow, again feparated it. He feems to have fallen into an error in faying, v. 1. 274, that the feeds of *Grewia* have no albumen; but there are fufficient diftinctions befides. (See GREWIA.) Befides the characters in the fructification, we may add, on the fcore of habit, that the inflorefcence of *Microcos* is panicled and terminal, that of *Grewia* axillary, and either fimple or fomewhat umbellate. We are enabled to ftrengthen the genus with two new fpecies, in addition to the original one.

1. M. *paniculata.* Smooth Microcos. Linn. Sp. Pl. 735. (M. foliis alternis oblongis acuminatis; Burm. Zeyl. 159. t. 74. Grewia Microcos; Linn. Syft. Nat. ed. 12. v. 2. 602. Juff. Ann. du Muf. v. 4. 89. Ait. Hort. Kew. ed. 2. v. 3. 301. Schageri-Cottam; Rheede Hort. Malab. v. 1. 105. t. 56.)—Leaves ovate, nearly fmooth.—Native of various parts of the Eaft Indies, in a fandy foil. A *fhrub* about a man's height, with alternate, round, leafy *branches,* which are a little downy when young only. *Leaves* alternate, on fhort roughifh ftalks, ovate, pointed, more or lefs oblique, from three to five inches long, and two broad, flightly and unequally ferrated, green on both fides, furnifhed from the bafe with three ribs, but the lateral ones vanifh about the middle, and are replaced by many large veins from the mid-rib, connected by an infinity of minute reticulations; both fides are a little rough to the touch, but naked, except a briftly roughnefs on the ribs. *Panicle* terminal, doubly or triply compound, the branches clothed with a fcurfy, fomewhat ftellated, pubefcence. *Flowers* reddifh, two or three together, in a common *involucrum* of about

about feven oblong downy deciduous leaves, refembling thofe of the perianth, which is lefs downy within. *Petals* not longer than the germen, obtufe, recurved, downy at the outfide.

2. M. *tomentofa*. Downy-leaved Microcos.—Leaves elliptical, very downy beneath.—A fpecimen of this is preferved in the herbarium of the younger Linnæus, marked *Grewia*, but without any indication of its native country. The *branch* is round, clothed with denfe rufty down, as are the *footftalks*, *flower-ftalks*, and backs of the *leaves*, the latter part being very foft. The *leaves* are the fize of the former, but elliptical and blunt, with a fhort point, and obfoletely ferrated chiefly towards the extremity. Their upper furface feels foft, from fcarcely vifible downinefs. The *panicle* is much like the foregoing, but the leaves of the *involucrum* are linear, narrow, and more diftant; others refembling them, but three-cleft, being fcattered about the lower part of the *panicle*, fo that they ought rather to be called *bracteas*.

3. M. *fcabra*. Rough-leaved Microcos.—Leaves oblong, heart-fhaped at the bafe, rough at the back.—Sent from Amboyna, by the late Mr. Chriftopher Smith. A larger fpecies than either of the former; its *branches*, *ftalks*, and backs of the *leaves* rough and harfh to the touch. The *leaves* are a foot long or more, four or five inches broad, pointed, obliquely heart-fhaped at the bafe, with five radiating hifpid ribs, and innumerable tranfverfe, parallel, reticulated veins; the margin is flightly uneven; the upper furface rather fhining and fmooth, except the ribs; the under opaque, and minutely hifpid, with ftarry, finally deciduous, hairs. *Panicle* ample, fpreading, repeatedly branched, terminal, but attended by axillary branches, likewife doubly compound, from fome of the upper leaves. *Involucral* leaves, embracing two or three flowers, dilated, membranous, downy, often palmate; the *bracteas* which refemble them, under each branch of the panicle, more decidedly palmate. *Flowers* the fize of the two former, but much more abundant. *Petals* lanceolate, tapering at the bafe, as long as the calyx, hairy at their backs.

We have feen nothing of the fruit of thefe two laft fpecies, but their inflorefcence, with the peculiar involucral leaves or bracteas, being fo unlike in all, and the ftructure of the flowers, as far as we can inveftigate it, agreeing equally well, it is prefumed there can be little uncertainty about their genus, if *Microcos* be allowed that rank at all. S.

MICROCOSM, Μικροκοσμος; formed from μικρος, *little*, and κοσμος, *world*, a Greek term, literally fignifying *little world*; chiefly underftood of *man*, who is fo called by way of eminence, as being an epitome of all that is wonderful in the great world, or macrocofm.

MICROCOSMETER, a name given by Dolæus to an imaginary being, which he fuppofes to refide in the brain, and direct all the actions.

MICROCOUSTICS, the fame with microphones.

MICROGRAPHIA, MICROGRAPHY, compounded of μικρος, *fmall*, and γραφη, *defcription*, a defcription of the parts and portions of objects that are too fmall to be viewed without the affiftance of a microfcope.

MICROLÆNA, in *Botany*, feems to be formed of μικρος, *fmall*, and ληνος, *wool*, alluding to the little bearded ftalk of the flower within the calyx. Brown Prod. Nov. Holl. v. 1. 210.—Clafs and order, *Tetrandria Digynia*. Nat. Ord. *Gramina*.

Eff. Ch. Calyx fingle-flowered, of two minute valves. Corolla fupported by a bearded ftalk, longer than the calyx, double, each of two valves, fmooth; thofe of the outermoft nearly equal, each with a terminal awn. Nectary of two oppofite fcales, alternate with the valves of the corolla. Stigmas feffile, feathery.

1. M. *ftipoides*. Br. (Ehrharta ftipoides; Labill. Nov Holl. v. 1. 91. t. 118.)—Gathered by M. Labillardiere in Van Diemen's land, and by Mr. Brown at Port Jackfon.—A fmooth grafs, about a foot and a half high. *Stem* round, flender, fimple, leafy. *Leaves* fpreading, fhort, flat, taper pointed, with very long fheaths, and a jagged ftipula. *Panicle* a fpan long, capillary, drooping, fimply branched. The bearded ftalk on which the flower ftands within the calyx, and the long awned glumes, give this grafs the afpect of an *Andropogon*, or *Stipa*. The French author defcribes and figures fix *ftamens*, and therefore referred the plant to *Ehrharta*, with which it has no other character in common, nor fcarcely any agreement in afpect. Mr. Brown, after repeated examinations, declares it to be certainly tetrandrous. The *ftigmas* are two, feffile and feathery. *Seed* elliptic-oblong, flightly compreffed, enclofed in the permanent hufks of the corolla. The *nectary* is extremely minute.

MICROLEUCONYMPHÆA, one of Boerhaave's fefquipedalian names, fuch as he diftributed plentifully among the Proteaceous family, and which is equivalent to Small-white-water-lily. He applied it to the plant now more happily termed HYDROCHARIS; fee that article.

MICROLOGUS, Μικρολογος, from μικρος, *parvus*, and λογος, *ratio*, *fermo*, that which gives reafons for obfcure and minute things, a minute enquiry into latent things: the title given by Guido d'Arezzo to his treatife on mufic, in which his fyftem is unfolded.

The moft curious part of the micrologus is the chapter "De Diaphonia, et Organi jura;" as it fhews the ftate of mufic at the time it was written, and gives fuch fpecimens of the firft rude attempts at harmony as may be fafely pronounced authentic. See GUIDO, HEXACHORD, and COUNTERPOINT.

MICROLOMA, in *Botany*, from μικρος, *fmall*, and λωμα, *a fringe*, the five tufts of hairs, alternate with the fcales, in the middle of the flower, having altogether that appearance. Brown Tr. of the Wernerian Society, v. 1. 53. (Ceropegia; Lamarck Illuftr. t. 179.)—Clafs and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juff. *Afclepiadeæ*, Brown.

Eff. Ch. Corolla pitcher-fhaped, with an inflated angular tube, much longer than the limb, naked at the mouth. Scales five, inferted into the tube under each finus, alternate with as many tufts of hair. Stamens without a crown. Anthers arrow-fhaped, tipped with a membrane; maffes of pollen compreffed, attached by the apex, pendulous. Stigma with a fmall point. Follicles . . . . .

A genus of twining flender *fhrubs*, with oppofite *leaves*, and *umbels* inferted between the *footftalks*. It is formed of the two Linnæan Cape fpecies of *Ceropegia*, which Mr. Brown obferves are widely different from the original fpecies of that genus. See CEROPEGIA, (by miftake CEROPEGIUM).

1. M. *fagittatum*. (Ceropegia fagittata; Linn. Mant. 215. Lamarck fig. 1. Cynanchum radice glandulofa, foliis anguftis finuatis, floribus urceolatis miniatis; Burm. Afr. 36. t. 15.)—Leaves arrow-fhaped, downy. Limb of the corolla rather acute.—Native of the Cape of Good Hope. *Root* of feveral oblong flefhy knobs. *Stems* two or three, flender, twining, fomewhat branched. *Leaves* on fhortifh ftalks, linear-oblong, revolute, dilated and arrow-fhaped at the bafe. *Flowers* in fmall hairy lateral umbels, fcarlet, with a fharp hairy *calyx*. The angles of the *corolla* alfo are downy.

2. M. *lineare.* (Ceropegia tenuifolia; Linn. Mant. 215. Syst. Veg. ed. 14. 255. Lamarck fig. 2. Periploca tenuifolia; Linn. Sp. Pl. 310, β. Cynanchum linearibus foliis acutis, floribus urceolatis rubris; Burm. Afr. 37. t. 16. f. 1.)—Leaves linear, smooth. Limb of the corolla very blunt.—Native of the Cape of Good Hope. The *root* is tuberous. Habit very like the foregoing, but the *leaves* are more narrow, strictly linear throughout, and smooth. *Flowers* red, differing from the former in the very oblique and obtuse form of the segments of their limb.

Mr. Brown appears to have, by mistake, copied the Linnæan specific name *tenuiflora* instead of *tenuifolia*, which last need not have been changed, though the appellation he has chosen we confess to be more particularly expressive.

MICROMETER, an astronomical machine, which, by means of a very fine screw, serves to measure extremely small distances in the heavens; as the apparent diameters of the planets, to a great degree of accuracy.

The word comes from the Greek μικρος, *parvus*, and μετρον, *mensura*: because a small length, *e. g.* an inch, is hereby divided into vast numbers of parts, *e. g.* in some 2800, and in others more.

This instrument is so contrived as to move a fine wire parallel to itself, in the plane of the picture of an object, formed in the focus of a telescope, and with great exactness to measure its perpendicular distance from a fixed wire in the same plane; and thus are measured small angles, subtended by remote objects at the naked eye. *E. G.* Let a planet be viewed through a telescope: and when the parallel wires are opened to such a distance as to appear exactly to touch two opposite points in the circumference of the planet, it is evident, that the perpendicular distance between the wires is then equal to the diameter of the picture of the planet, formed in the focus of the object-glass. Let this distance, whose measure is given by the mechanism of the micrometer, hereafter described, be represented by the line pq, *Plate* X. *Optics*, *fig.* 5; then, since the measure of the focal distance $q4$ may be also known, the ratio of q L to qp, that is, of the radius to the tangent of the angle q L p, will give the angle itself by a table of sines and tangents; and this angle is equal to the opposite angle P L Q, which the real diameter of the planet subtends at L, or at the naked eye. There is some controversy about the invention of the micrometer. Messrs. Auzout and Picard have the credit of it in common fame, as being the first who published it, in the year 1666; but Mr. Townley, in the Philosophical Transactions, reclaims it for one of our own countrymen, Mr. Gascoigne. He relates, that from some scattered papers and letters of this gentleman, he had learnt, that, before our civil wars, he had invented a micrometer, of as much effect as that since made by M. Auzout, and had made use of it for some years, not only in taking the diameters of the planets, and distances upon land, but in determining other matters of nice importance in the heavens; as the moon's distance, &c.

Mr. Gascoigne's instrument fell into the hands of Mr. Townley, who says, that by the help of it he could make above forty thousand divisions in a foot. This instrument being shewn to Dr. Hooke, he gave a drawing and description of it, and proposed several improvements in it, which may be seen in the Philosophical Transactions, Abr. vol. i. p. 217. Mr. Gascoigne divided the image of an object, in the focus of the object-glass, by the approach of two pieces of metal, ground to a very fine edge, in the place of which Dr. Hooke would substitute two fine hairs stretched parallel to one another. Two other methods of Dr. Hooke, different from this, are described in his Posthumous Works, p. 497, &c. An account of several curious observations which Mr. Gascoigne made by the help of his micrometer, particularly in the mensuration of the diameter of the moon and other planets, may be seen in the Phil. Trans. vol. xlviii. p. 190; where Dr. Bevis refers to an original letter of Mr. Gascoigne, to Mr. Oughtred, written in 1640—1, for an account given by the author of his own invention, &c.

Monf. de la Hire, in a discourse on the era of the inventions of the micrometer, pendulum clock, and telescope, read before the Royal Academy of Sciences in 1717, makes M. Huygens the inventor of the micrometer. That author, he observes, in his Observations on Saturn's Ring, &c. published in 1659, gives a method of finding the diameters of the planets by means of a telescope; *viz.* by putting an object, which he calls *virgula*, of a proper bigness to take in the distance to be measured, in the focus of the convex object-glass: in this case, says he, the smallest object will be seen very distinctly in that place of the glass. By such means, he adds, he measured the diameters of the planets, as he there delivers them.

This micrometer, M. De la Hire observes, is so very little different from that published by the marquis de Malvasia, in his Ephemerides, three years after, that they ought to be esteemed the same: and the micrometer of the marquis differed yet less from that published four years after his by Auzout and Picard. Hence, M. De la Hire concludes, that it is to M. Huygens the world is indebted for the invention of the micrometer; without taking any notice of the claim of our countryman Mr. Gascoigne, which, however, is prior by many years to any of them.

M. De la Hire says, that there is no method more simple or commodious for observing the digits of an eclipse, than a net in the focus of the telescope. These, he says, were generally made of silken threads, and for this particular purpose six concentric circles had also been made use of, drawn upon oiled paper; but he advises to draw the circles on very thin pieces of glass, with the point of a diamond. He also gives several particular directions to assist persons in using them. In another memoir he shews a method of making use of the same net for all eclipses, by using a telescope with two object-glasses, and placing them at different distances from one another. Ac. Par. 1701, and 1717.

MICROMETER, *Construction and Use of the.* Wolfius describes a micrometer of a very easy and simple structure, first contrived by Kirchius, thus:

In the focus of a telescope fit a brass or iron ring A B (*Plate* X. *Optics*, *fig.* 6.) with female screws diametrically opposite to each other; into these insert male screws C E and F B, of such length as that they may be turned in the tube, so as to touch each other: and with this instrument very small spaces in the heavens may be accurately measured.

For when any objects, viewed through a tube, appear contiguous to the screws, if these be turned till they just touch two opposite points, whose distance is to be measured, it will be evident how many threads of the screw they are apart. To determine how many seconds answer to each thread, applying the tube towards the heavens, turn the screws till they touch two points, whose distance is already accurately known; and observe the number of threads corresponding to that interval; thus, by the rule of three, a table may be made of the seconds corresponding to the several threads; by means of which, without greater labour, the distances of any points may be determined.

The structure of another micrometer, with the manner of fitting it to the telescope, and applying it, is as follows: A B C g (*fig.* 7.) is a rectangular brass frame, the side A B being about three inches long, and the side B C, as likewise the

the oppofite fide A g, about fix inches; and each of the three fides about eight-tenths of an inch deep: the two oppofite fides of this frame are fcrewed to the circular plate, to be mentioned hereafter.

The fcrew P, which has exactly forty threads in an inch, being turned round, moves the plate G D E F, along two grooves made near the tops of the oppofite fides of the frame; and the fcrew Q, having the fame number of threads in an inch as P, moves the plate R N M Y along two grooves, made near the bottom of the faid frame, in the fame direction as the former plate moves, but with only half the velocity of that other; thefe fcrews are turned both at once, and fo the plates are moved along the fame way, by means of a handle turning the endlefs fcrew S, whofe threads fall in between the teeth of the pinions on the fcrews P and Q. And note, that two half revolutions of the endlefs fcrew S carry the fcrew P exactly once round.

The fcrew P turns the hand a, faftened to it, over a hundred equal divifions, made round the limb of a circular plate, to which the above named two oppofite fides of the frame are fcrewed at right angles; the teeth of the pinion on the fcrew P, whofe number is 5, take into the teeth of a wheel on the backfide of the circular plate, whofe number is 25. Again, on the axis of this wheel is a pinion of two, which takes into the teeth of another wheel, moving about the centre of the circular plate, on the outfide of it, and having fifty teeth; this laft wheel moves the leffer hand b once round the above mentioned circular plate in the $\frac{1}{100}$dth part of the time the hand a is moving round: for becaufe the number of teeth in the pinion of the fcrew P is 5, and the number of teeth of the wheel this pinion moves, is 20; therefore the fcrew P moves four times round in the time that wheel is moving once round. Further, fince there is a pinion of two which takes into the teeth of a wheel, whofe number is 50; therefore this wheel with 50 teeth will move once round in the time that the wheel of 20 teeth moves 25 times round; and, confequently, the fcrew P, or hand a, muft move a hundred times round in the fame time as the wheel of 50 teeth, or the hand b, has moved once round.

Hence it follows, that if the circular plate W, which is faftened at right angles to the other circular plate, be divided into two hundred equal parts, the index x, to which the handle is faftened, will move five of thofe parts in the fame time in which the hand a moves one of the hundred divifions round the limb of the other circular plate. Thus by means of an index x, and plate W, every fifth part of each of the divifions round the other plate may be known.

Further, fince each of the fcrews P and Q have exactly forty threads in an inch; therefore the upper plate G D E F will move one inch while the hand a moves forty times round; the four-thoufandth part of an inch while the hand moves over one of the divifions round the limb; and the twenty-thoufandth part of an inch while the index x moves one part of the two hundred round the limb of the circular plate W: and the under plate R N M Y will move half an inch, the two-thoufandth part of an inch, and the ten-thoufandth part of an inch, the fame way, in the faid refpective times.

Hence, if the under plate, having a large round hole in it, be fixed to a telefcope, fo that the frame is moveable, together with the whole inftrument, except the faid lower plate; and the ftraight fmooth edge H I, of the fixed plate A B I H; as likewife the ftraight fmooth edge D E, of the moveable plate G D E F, be perceivable through the round hole in the under plate, in the focus of the object-glafs; then when the handle of the micrometer is turned, the edge H I, of the narrow plate A B I H, fixed to the frame, and D E, of the moveable plate, will appear through the telefcope equally to aproach to, or recede from, each other.

By thefe edges we fhall be able to meafure the apparent diameters of the fun, moon, &c. the manner of doing which take as follows:

Suppofe, in looking at the moon through the telefcope, you have turned the handle till the two edges D E and H I are opened, fo as juft to touch or clafp the moon's edges; and that there were twenty-one revolutions of the hand a to complete that opening: firft fay, as the focal length of the object-glafs, which fuppofe ten feet, is to radius, fo is one inch to the tangent of an angle fubtended by one inch in the focus of the object-glafs; which will be found twenty-eight minutes thirty feconds: again, becaufe there are exactly forty threads of the fcrews in one inch; fay, if forty revolutions of the hand a give an angle of 28′ 30″, what angle will twenty-one revolutions give? The anfwer will be, fifteen minntes eight feconds; and fuch was the moon's apparent diameter. And fo may the apparent diameters of any other objects be taken. It muft be here obferved, that the divifions on the top of the plate G D E F are diagonal divifions of the revolutions of the fcrews, with diagonal divifions of inches againft them; thus, as the faid plate flides along, thefe diagonals are cut by divifions made on the edge of the narrow plate K L, fixed to the oppofite fide of the frame by means of two fcrews. Thefe diagonal divifions ferve for a regifter to count the revolutions of the fcrews, and to fhew how many there are in an inch, or the parts of an inch.

Dr. Derham tells us, that his micrometer is not, as ufually, to be put into a tube, but to meafure the fpectres of the fun on paper (of any radius), or to meafure any part of them. By this means, he can eafily, and very exactly, with the help of a fine thread, take the declination of a folar fpot at any time of the day; and, by his half-feconds watch, meafure the diftance of the fpot from the fun's eaftern and weftern limb.

A micrometer of a better fort is made in this manner: in the middle of an oblong plate of brafs, (A B, *Plate* X. *Optics*, *fig.* 8.) there is cut an oblong hole, $a\,b\,c\,d\,e\,f$, (to be placed in the focus of a telefcope,) having a fine wire, $b\,e$, extended lengthways over the middle of it, at right angles, to two flender brafs bars or fights $g\,h$, $i\,k$, lying crofs the hole; of which $g\,h$ is fixed to the plate A B by fcrews at g and h, but $i\,k$ is moved parallel to $g\,h$ by twifting a round knob C fixed upon one end of a long iron fcrew D E, which turns upon a tapering point at its end D, while its other end turns round in a hole at E in the centre of an index plate E F, fixed at right angles to the main plate A B. The long fcrew D E works through two hollow fcrews in two cubical blocks of brafs, fixed behind the plate $l\,m$, bent fquare to the plate $n\,o$, that flides upon the main plate A B, either backward or forward, and carries a perpendicular arm $o\,p$ extended over the hole $b\,e$; while p, the extremity of the arm $o\,p$, flides under a brafs ledge $q\,r$, fcrewed to the main plate A B, along the fide of the hole. One fide, $s\,t$, of the moveable fight-plate $i\,k\,s\,t$, lies over the arm $o\,p$, being fixed to it by the flat-headed fcrews at s and t, the holes in the plate $s\,t$ being oblong or larger than the fhanks of the fcrews, to give liberty for placing the edge $i\,k$ coincident with $g\,h$, when carried up to it by turning the fcrew D E by the knob C; the part $i\,k$, which projects over the arm $o\,p$, being hammered down to lie flat upon the main plate A B. The edge $i\,k$, after this adjuftment, will always move parallel to the edge $g\,h$; its inclination to the fcrew D E being every where the fame, provided the fcrew be ftraight, and the interval of the concave fcrews behind $l\,m$ be fufficiently great and their motion fteady. For this purpofe about a quarter-round

round of a third concave ſcrew preſſes upon the long ſcrew D E at v, the block of it being fixed to the middle of a ſpringing plate $w\,v\,x$; whoſe extremities lying behind the blocks at l, m, not ſo near as to touch them, are preſſed towards them with ſcrews at w and x; which occaſions the block at v to ſpring upon the ſcrew D E, and to hold it tight to the oppoſite ſide of the concave ſcrews at l, m. To prevent any motion lengthways in the ſcrew D E, its tapering point D turns in a hollow point at the end of an oppoſite ſcrew y, which working through a fixed block at z, holds up the ſhoulder of the long ſcrew D E, againſt the back of the index-plate, where its neck is inſerted.

The two indexes upon the plate E F ſhew the number of revolutions and parts of a revolution of the ſcrew D E, anſwering to the interval of the ſights $g\,b$, $i\,k$. In the outward plate there is a circular ſlit $\alpha\,\beta\,\gamma$, which diſcovers part of the diviſions upon the circumference of an inner plate, turned about a centre by two wheels and pinions within: ſo that for every revolution of the ſcrew, an index E F, which ſhews the parts of it, one diviſion upon the plate $\alpha\,\beta\,\gamma$, paſſes by a fixed point at β; which ſhews the number of revolutions anſwering to the intervals of the ſights $g\,b$, $i\,k$.

This micrometer received a very great improvement by an ingenious contrivance of the reverend Dr. James Bradley, profeſſor of aſtronomy at Oxford, for turning it in its own plane about the interſection δ of the fixed ſight $g\,b$, and of the tranſverſe wire $b\,\delta\,e$, without ſtirring the teleſcope: which is thus executed. Upon the backſide of the main-plate turned upwards, and here repreſented by the parallelogram G H I K, (*fig.* 9.) there is laid ſuch another plate L M N O, of the ſame breadth and thickneſs but ſomewhat ſhorter; in the middle of which there is an oblong hole, anſwering to the other in the lower plate, but ſomewhat larger; being terminated at its ſides by the ſtraight lines $\varepsilon\,\zeta$, $\eta\,\theta$, and at its ends by the concave arches $\theta\,\iota\,\varepsilon$, $\zeta\,\kappa\,\eta$, whoſe common centre is the point δ above-mentioned. The concave arch $\varepsilon\,\iota\,\theta$ ſlides round this centre againſt a concentric convex arch of an annular plate $\lambda\,\mu\,\nu$; ſomewhat longer than the concave arch, of the ſame thickneſs as the upper parallelogram, and ſtrongly ſcrewed to the under one, round that end of the hole which is neareſt to the centre δ; and at the ſame time the other concave arch $\zeta\,\kappa\,\eta$ ſlides alſo againſt another concentric convex arch $o\,\varpi$, of another annular plate juſt as thick as the upper parallelogram, and ſtrongly ſcrewed to the under one. This convex arch $o\,\varpi$ is ſhorter than the contiguous concave one $\zeta\,\kappa\,\eta$, to give room for the circular motion of the plates; which are held together by two annular plates ſimilar to $\lambda\,\mu\,\nu$ and $o\,\varpi$, but ſomewhat broader, to cover the coincident arches when laid over them, and ſcrewed down to the reſpective annular plates underneath. The circular motion upon theſe arches about their centre δ, is gradually given to the upper parallelogram by an endleſs ſcrew at ϱ, having an axis $\sigma\,\tau$ laid croſs the end of the under parallelogram, and turning upon a point at one end, and in a collar at the other, both fixed to the under plate; while the ſpiral thread ϱ moves the teeth of a braſs arch fixed at v, to the end of the upper parallelogram.

To hold the micrometer in the tube of a teleſcope, along each ſide of the upper parallelogram there is fixed a long braſs plate about an inch broad; having its oppoſite ſides bent contrary ways, ſo as to form two oppoſite ledges, about one-eighth of an inch broad, at right angles to the intermediate part of the plate, as repreſented in the figure. One of the ledges of each plate is placed inwards along the ſides of the upper parallelogram, and is firmly fixed to it by ſeveral ſcrews. The figure $\varphi\,\chi\,\psi\,\omega$ repreſents one of the equal and oppoſite holes cut in the ſides of a ſquare tube, through which the micrometer is put; the notches $\phi\,\chi$ being made to receive the ledges of the ſide-plates, to keep the plate of the micrometer perpendicular to the tube at a juſt diſtance from the object-glaſs. Which diſtance being once determined by trials, as above explained, muſt be kept invariable in all obſervations, by ſtops or pins, if the tube conſiſts of two or more joints that draw in and out.

The Meaſures of the Micrometer.

	Inches.
The length of the plate A B	8.0
Its breadth M N	3.6
Its thickneſs	0.$\frac{1}{2}$
Length of the hole $b\,e$	3.5
Its breadth $g\,b = \delta\,e$	2.2
Breadth of the hole in the other plate at $\zeta\,\eta$	2.6
Length of the ſcrew D E	5.5
Its thickneſs	0.3
The line A b	1.6
The interval $l\,m = w\,x$	3.0
Length of the ſide cheeks	4.5
Their breadth	0.8
Their ledges	0.2
Diameter of the index-plate	3.1
Its thickneſs (being double with two wheels within)	0.3
The greateſt opening of the ſights $g\,b$, $i\,k = \delta\,e$	2.2
Threads of the ſcrew in an inch, 40	

The inch is divided by the index-plates into 40 times 40, or 1600 equal parts. Inſtead of the braſs ſights $g\,b$, $i\,k$, two others, with parallel wires a, may be ſcrewed on at pleaſure.

When the ſight-plates are made to coincide, the two indexes of the revolutions and their parts muſt be ſet to the beginning of the numerations upon the index-plates. Then as the ſights are opened, it is evident from the make of a ſcrew, that the numbers of revolutions will be as the intervals of the ſights, and conſequently as the angles ſubtended by them at the centre of the object-glaſs; the intervals being inſenſibly different from the arches that meaſure theſe ſmall angles. Therefore when any one angle correſponding to a given number of revolutions, is determined by experiment, an angle correſponding to any other number of revolutions may be found by the rule of three. And thus may tables be made to ſhew by inſpection the number of minutes and ſeconds in an angle anſwering to any given number of revolutions and parts.

To determine ſome one angle, the larger the better, becauſe the ſame error in the determination will be proportionably ſmaller in a given angle deduced from it; fix the teleſcope upon any known ſtar in the equator, or very near it, and open the ſights to their utmoſt limit and note the number of revolutions of the ſcrew. Then by a pendulum-clock obſerve the interval of time in the ſtar's tranſit over the given interval of the ſights, and having turned it into minutes and ſeconds of an arch, they are the meaſure of the angle required. But if the ſtar be remote from the equator, the number of minutes and ſeconds thus found, muſt be diminiſhed in the ratio of the radius of the ſine of the ſtar's diſtance from the pole. To this micrometer Dr. Bradley applied an ingenious contrivance, by which it is adapted for taking the difference of right aſcenſion and declination of ſuch objects as are at a greater diſtance than the teleſcope will take in at once, but which paſs through the aperture of it at different times. Let A B C (*fig.* 10.) repreſent a flat ring of braſs, fixed in the focus of the teleſcope; and $a\,b\,c$ a ſmaller

ſmaller concentric ring lodged in a circular groove turned within the larger, and kept in the groove by three ſmall plates of braſs fixed to the outward ring, and extended over the edge of the inner one. Upon the inner ring is fixed a concentric arch of a wheel *de*, having teeth cut in its convexity, which are driven round by the threads of an endleſs ſcrew, whoſe axis D E F turns in a collar at E, and upon a point at F, both fixed to the outward ring. The hairs *g h*, *i k*, croſs at right angles in *f*, the centre of the rings; and when the teleſcope is ſo fixed that the image of the ſtar falls upon *f*, let it move along any line *f q*, and by turning the ſcrew D E F, and by conſequence the hair *f k*, about the fixed point *f* till it touches the ſtar at *q*, it will then coincide with the tract of the ſtar's motion; and then all other ſtars will move parallel to it as was required. To find the difference of declination of two ſtars, he obſerves the times of their appulſes to the edges of two ſlender braſs bars *g i o*, *g k p*, fixed to the inner ring, and equally inclined to its diameter *g h* in ſuch angles that the perpendiculars *f i*, *f k*, on each ſide of *f g*, ſhall be ſeverally equal to half *f g*; and conſequently that the whole baſe *i k*, of the equicrural triangle *i g k*, ſhall be equal to its perpendicular height *f g*; and by conſequence that the difference of any two baſes *i f k*, *l m n*, ſhall be equal to *f m*, the difference of their heights; ſo that the difference of the times of the tranſits of two ſtars over theſe baſes, may give the difference of their declinations. Smith's Optics, art. 876, &c.

M. Caſſini firſt made uſe of four croſs hairs or threads, interſecting one another at half right angles, for determining the difference of right aſcenſions and declinations of objects near the ſame parallel: but the micrometer, according to its latter improvements, will anſwer this purpoſe with greater exactneſs. Dr. Maſkelyne has publiſhed directions for the uſe of it, extracted from Dr. Bradley's papers, in the Philoſ. Tranſ. vol. lxii. art. 6. p. 46, &c.

A conſiderable improvement with regard to the micrometer, was communicated to the Royal Society, in 1743, by Mr. Servington Savery, an account of which, extracted from the minutes by Mr. Short, was publiſhed in the Phil. Tranſ. for 1753, vol. xlviii. art. 26. The firſt hint of ſuch a micrometer was ſuggeſted by M. Roemer, in 1675; and M. Bouguer propoſed a ſimilar conſtruction to that of Mr. Savery, in 1748, for which ſee HELIOMETER. The late Mr. Dollond made a farther improvement in this kind of micrometer, an account of which was given to the Royal Society by Mr. Short, and publiſhed in the Phil. Tranſ. vol. xlviii. art. 27. Inſtead of two object glaſſes, he uſed only one, which (after having been truly ground and well centered) he neatly cut into two ſemi-circles, and fitted each ſemi-circle in a metal frame, ſo that their diameters ſliding in one another, by means of a ſcrew, may have their centres ſo brought together as to appear like one glaſs, and ſo form one image; or by their centres receding, may form two images of the ſame object: it being a property of ſuch glaſſes, for any ſegment to exhibit a perfect image of an object, although not ſo bright as the whole glaſs would give it. If proper ſcales are fitted to this inſtrument, ſhewing how far the centres recede, relative to the focal length of the glaſs, they will alſo ſhew how far the two parts of the ſame object are aſunder, relative to its diſtance from the object glaſs; and conſequently give the angle under which the diſtance of the parts of that object are ſeen. This divided object-glaſs micrometer, which was applied by the late Mr. Dollond to the object end of a reflecting teleſcope, has been with equal advantage adapted by his ſon to the end of an achromatic teleſcope, is ſo eaſy of uſe, and affords ſo large a ſcale, that it is generally looked upon by aſtronomers as the moſt convenient and exact inſtrument for meaſuring ſmall diſtances in the heavens. However, the common micrometer is peculiarly adapted for meaſuring differences of right aſcenſion, and declination of celeſtial objects, but leſs convenient and exact for meaſuring their abſolute diſtances; whereas the object-glaſs micrometer is peculiarly fitted for meaſuring diſtances, but has been generally ſuppoſed improper for meaſuring differences of right aſcenſion and declination. But Dr. Maſkelyne has found that the latter may be applied with very little trouble, and ſmall additional expence to this other purpoſe as well as the former; and he has furniſhed the directions neceſſary to be followed when it is uſed in this manner. The addition requiſite for this purpoſe is a cell, containing two wires, interſecting each other at right angles, placed in the focus of the eye-glaſs of the teleſcope, and moveable round about, by the turning of a button. For the deſcription of this apparatus, together with the method of applying and uſing it, we ſhall refer to Dr. Maſkelyne's paper on the ſubject, in the Phil. Tranſ. vol. lxi. part ii. art. 49. p. 536.

After all, the uſe of the object-glaſs micrometer is attended with difficulties, ariſing from the alterations in the focus of the eye, which are apt to cauſe it to give different meaſures of the ſame angle at different times. In order to obviate theſe difficulties, Dr. Maſkelyne, in 1776, contrived a priſmatic micrometer, or a micrometer conſiſting of two achromatic priſms, or wedges, applied between the object-glaſs and eye-glaſs of an achromatic teleſcope, by moving of which wedges nearer to, or farther from, the object-glaſs, the two images of an object produced by them appeared to approach to or recede from each other, ſo that the focal length of the object-glaſs becomes a ſcale for meaſuring the angular diſtance of the two images. The rationale and uſe of this micrometer are explained in the Phil. Tranſ. vol. lxvii. part ii. art. 36. p. 799, &c. A ſimilar invention by the abbé Rochon, and improved by the abbé Boſcovich, was alſo communicated to the Royal Society, and publiſhed in the ſame volume of the Tranſactions, art. 35. p. 789, &c.

Mr. Ramſden, an ingenious optician, has deſcribed two new micrometers, which he has contrived with a view of remedying the defects of the object-glaſs micrometer. One of theſe is a catoptric micrometer, which, beſide the advantage it derives from the principle of reflection, of not being diſturbed by the heterogeneity of light, avoids every defect of other micrometers, and can have no aberration, nor any defect ariſing from the imperfection of materials, or of execution; as the extreme ſimplicity of its conſtruction requires no additional mirrors or glaſſes to thoſe required for the teleſcope; and the ſeparation of the image being effected by the inclination of the two ſpecula, and not depending on the focus of any lens or mirror, any alteration in the eye of an obſerver cannot affect the angle meaſured. It has peculiar to itſelf the advantages of an adjuſtment, to make the images coincide in a direction perpendicular to that of their motion; and alſo of meaſuring the diameter of a planet on both ſides of the zero, which will appear no inconſiderable advantage to obſervers, who know how much eaſier it is to aſcertain the contact of the external edges of two images than their perfect coincidence. A (*fig.* 11.) repreſents the ſmall ſpeculum of a reflecting teleſcope of Caſſegrain's conſtruction, to which this micrometer is adapted, divided into two equal parts; one of which is fixed on the end of the arm B; the other end of the arm is fixed on a ſteel axis X, which croſſes the end of the teleſcope C. The other half of the mirror A is fixed on the arm D, which arm at the other end terminates in a ſocket *y*, that turns on the axis X; both arms are prevented from bending by the braces, *a*, *a*. G repreſents a double ſcrew, having one part, *e*, cut into double

double the number of threads in an inch to that of the part *g*; the part *e* having a hundred threads in one inch, and the part *g* fifty only. The ſcrew, *e*, works in a nut F, in the ſide of the teleſcope, while the part *g* turns in a nut H, which is attached to the arm B; the ends of the arms B and D, to which the mirrors are fixed, are ſeparated from each other by the point of the double ſcrew preſſing againſt the ſtud *b*, fixed to the arm D, and turning in the nut H on the arm B. The two arms, B and D, are preſſed againſt the direction of the double ſcrew, *e g*, by a ſpiral ſpring within the part *n*; by which means all ſhake or play in the nut H, on which the meaſure depends, is entirely prevented.

From the difference of the threads on the ſcrew at *e* and *g*, it is evident that the progreſſive motion of the ſcrew through the nut will be half the diſtance of the ſeparation of the two halves of the mirror, and conſequently the half mirrors will be moved equally in contrary directions from the axis of the teleſcope C.

The wheel V, fixed on the end of the double ſcrew, has its circumference divided into 100 equal parts, and numbered at every fifth diviſion with 5, 10, &c. to 100; and the index, I, ſhews the motion of the ſcrew with the wheel round its axis, while the number of revolutions of the ſcrew is ſhewn by the diviſions on the ſame index. The ſteel ſcrew, R, may be turned by the key S, and ſerves to incline the ſmall mirror at right angles to the direction of its motion.

The other micrometer, invented and deſcribed by Mr. Ramſden, is ſuited to the principle of refraction. This micrometer is applied to the erect eye-tube of a refracting teleſcope, and is placed in the conjugate focus of the firſt eye-glaſs; in which poſition, as the image is conſiderably magnified before it comes to the micrometer, any imperfection in its glaſs will be magnified only by the remaining eye-glaſſes, which in any teleſcope ſeldom exceeds five or ſix times; and beſides, the ſize of the micrometer glaſs will not be the $\frac{1}{100}$dth part of the area which would be required, if it were placed at the object-glaſs; and yet the ſame extent of ſcale is preſerved, and the images are uniformly bright in every part of the field of the teleſcope. This micrometer is repreſented in *Plate* XI. *Optics*, *fig.* 1. A is a convex or concave lens divided into two equal parts by a plane acroſs its centre; one of theſe ſemi-lenſes is fixed in a frame B, and the other in the frame E, which two frames ſlide on a plate H, and are preſſed againſt it by thin plates, *a*, *a*: the frames, B and E, are moved in contrary directions by turning the button D; L is a ſcale of equal parts on the frame B; it is numbered from each end towards the middle with 10, 20, &c. There are two verniers on the frame E, one at M, and the other at N, for the conveniency of meaſuring the diameter of a planet, &c. on both ſides of the zero. The firſt diviſion on both theſe verniers coincides at the ſame time with the two zeros on the ſcale L; and, if the frame is moved towards the right, the relative motion of the two frames is ſhewn on the ſcale L by the vernier M; but if the frame B be moved towards the left, the relative motion is ſhewn by the vernier N.

This micrometer has a motion round the axis of viſion, for the conveniency of meaſuring the diameter of a planet, &c. in any direction, by turning an endleſs ſcrew F, and the inclination of the diameter meaſured with the horizon is ſhewn on the circle, *g*, by a vernier on the plate V. The teleſcope may be adjuſted to diſtinct viſion by means of an adjuſting ſcrew, which moves the whole eye-tube with the micrometer nearer or farther from the object-glaſs, as teleſcopes are generally made; or the ſame effect may be produced in a better manner, without moving the micrometer, by ſliding the part of the eye-tube *m* on the part *n*, by help of a ſcrew or pinion. The micrometer is made to take off occaſionally from the eye-tube, that the teleſcope may be uſed without it. Phil. Tranſ. vol. lxix. part ii. art. 27.

Dr. Herſchel has applied a lamp micrometer to ſir Iſaac Newton's reflecting teleſcope. (See Phil. Tranſ. vol. lxxii. p. 165, &c. and vol. lxxiii. p. 5, &c.) Two moveable lamps, the light of which comes through two ſmall holes, are placed at a convenient diſtance from the teleſcope, in the direction at which you look at the image. Theſe points of light are looked at by the left eye, and brought, *e. g.* to the oppoſite ſides of a planet looked at by the right eye; and by meaſuring their diſtance from each other, and from the eye, the angle under which the magnified diameter appears will be known, which, divided by the magnifying power of the teleſcope, gives the apparent diameter required. The conſtruction of this micrometer is as follows: A B G C F E (*Plate* XI. *Optics*, *fig.* 5.) is a ſtand nine feet high, upon which a ſemi-circular board, *q h o g p*, is moveable upwards or downwards, in the manner of ſome fire-ſcreens, as occaſion may require, and is held in its ſituation by a peg, *p*, put into any one of the holes of the upright piece A B. This board is a ſegment of a circle of fourteen inches radius, and is about three inches broader than a ſemi-circle, to give room for the handles, *r* D, *e* P, to work. The uſe of this board is to carry an arm L, thirty inches long, which is made to move upon a pivot at the centre of the circle, by means of a ſtring, which paſſes in a groove upon the edge of the ſemicircle *p g o h q*; the ſtring is faſtened to a hook at *o*, (not expreſſed in the figure, being at the back of the arm L,) and paſſing along the groove from *o b* to *q*, is turned over a pulley at *q*, and goes down to a ſmall barrel *e*, within the plane of the circular board, where a double-jointed handle, *e* P, commands its motion. By this contrivance we ſee the arm, L, may be lifted up to any altitude from the horizontal poſition to the perpendicular, or be ſuffered to deſcend by its own weight below the horizontal to the reverſe perpendicular ſituation. The weight of the handle, P, is ſufficient to keep the arm in any given poſition; but if the motion ſhould be too eaſy, a friction ſpring applied to the barrel will moderate it at pleaſure.

In front of the arm, L, a ſmall ſlider, about three inches long, is moveable in a rabbet from the end L towards the centre backwards and forwards. A ſtring is faſtened to the left ſide of the little ſlider, and goes towards L, where it paſſes round a pulley at *m*, and returns under the arm from *m*, *n*, towards the centre, where it is led in a groove on the edge of the arm, which is of a circular form, upwards to a barrel (raiſed above the plane of the circular board) at *r*, to which the handle, *r* D, is faſtened. A ſecond ſtring is faſtened to the ſlider, at the right ſide, and goes towards the centre, where it paſſes over a pulley *n*, and the weight, *w*, which is ſuſpended by the end of this ſtring, returns the ſlider towards the centre, when a contrary turn of the handle permits it to act.

a and *b* are two ſmall lamps, two inches high, one inch and a half in breadth, by one inch and a quarter in depth. The ſides, back, and top, are made ſo as to permit no light to be ſeen, and the front conſiſts of a thin braſs ſliding door. The flame in the lamp, *a*, is placed three-tenths of an inch from the left ſide, three-tenths from the front, and half an inch from the bottom. In the lamp *b*, it is placed at the ſame height and diſtance, meaſuring from the right ſide. The wick of the flame conſiſts only of a ſingle very thin lamp-cotton thread; for the ſmalleſt flame being ſufficient, it is eaſier to keep it burning in ſo confined a place. In the

top

top of each lamp must be a little slit, lengthways, and also a small opening in one side near the upper part, to permit air enough to circulate to feed the flame. To prevent every reflection of light, the side opening of the lamp *a* should be to the right, and that of the lamp *b* to the left. In the sliding door of each lamp is made a small hole, with the point of a very fine needle, just opposite the place where the wicks are burning, so that when the sliders are shut down, and every thing dark, nothing shall be seen but two fine lucid points of the size of two stars of the third or fourth magnitude. The lamp, *a*, is placed so that its lucid point may be in the centre of the circular board, where it remains fixed. The lamp, *b*, is hung to the little slider, which moves in the rabbet of the arm, so that its lucid point, in a horizontal position of the arm, may be on a level with the lucid point in the centre. The moveable lamp is suspended upon a piece of brass, fastened to the slider by a pin exactly behind the flame upon which it moves as a pivot. The lamp is balanced at the bottom by a leaden weight, so as always to remain upright, when the arm is either lifted above, or depressed below, the horizontal position. The double-jointed handles, *r* D, *e* P, consist of light deal rods, ten feet long, and the lowest of them may have divisions, marked upon it near the end P, expressing exactly the distance from the central lucid point in feet, inches, and tenths.

From this construction we see, that a person at a distance of ten feet may govern the two lucid points, so as to bring them into any required position south or north preceding or following, from 0 to 90°, by using the handle P, and also to any distance from six-tenths of an inch to five or six and twenty inches, by means of the handle D. If any reflection or appearance of light should be left from the top or sides of the lamps, a temporary screen, consisting of a long piece of paste-board, or a wire-frame covered with black cloth, of the length of the whole arm, and of any required breadth, with a slit of half an inch broad in the middle, may be affixed to the arm by four bent wires, projecting an inch or two before the lamps, situated so that the moveable lucid point may pass along the opening left for that purpose.

Fig. 6. represents part of the arm L, half the real size; S, the slider; *m*, the pulley, over which the cord, *x t y z*, is returned towards the centre; *v*, the other cord going to the pulley, *n*, of *fig.* 5; R, the brass piece moveable upon the pin *c*, to keep the lamp upright. At R is a wire rivetted to the brass piece, upon which is held the lamp by a nut and screw. *Figs.* 7, and 8, represent the lamps, *a*, *b*, with the sliding doors open, to shew the situation of the wicks. W is the leaden weight, with a hole, *d*, in it, through which the wire R, of *fig.* 6, is to be passed, when the lamp is to be fastened to the slider S. *Fig.* 9. represents the lamp *a*, with the sliding door shut; *l*, the lucid point; and *i k*, the openings at the top, and *s* at the sides, for the admission of air.

Every ingenious artist will soon perceive that the motions of this micrometer are capable of great improvement, by the application of wheels and pinions, and other well known mechanical resources; but, as the principal object is only to be able to adjust the two lucid points to the required position and distance, and to keep them there for a few minutes, while the observer goes to measure their distance, it will not be necessary to say more upon the subject.

Mr. Smeaton's equatorial micrometer, together with its use in an observation of a transit of Mercury, is described and exhibited in the Phil. Trans. vol. lxxvii. art. 33. We have the description of a micrometer for taking the angle of position, with drawings for illustrating its construction, as it was executed by Messrs. Nairne and Blunt, in a paper by Dr. Herschel, Phil. Trans. vol. lxxi. p. 500, and a further account of its use and the mode of improving it by Dr. Herschel, Phil. Trans. vol. lxxv. p. 46. Mr. Troughton's micrometer is applied to the eye-piece of a telescope for measuring exceedingly small angles, as the diameters of the heavenly bodies, &c. *Fig.* 2. is an orthography of this instrument projecting endways; *fig.* 3. is a section of the box containing the wires; and *fig.* 4. a section lengthways: the same letters, as far as they can, are used in all the figures. *Figs.* 2 and 4, A is an eye-tube containing a convex lens at each end; this slides in another tube, *d d*, so as to adjust the glass to distinct vision of the wires; the tube, *d d*, is screwed into another, *b b*, which is much larger, through this a thin long box, D D D, containing the wire slides. The micrometer is screwed to the telescope by a male screw, *e e*, (*fig.* 4.) in the same piece with which is a circular plate, *f f*, cut all round with fine teeth; this plate fits against the flat bottom of the box, *b*, and turns round concentrically with it by means of a ring, *k*, fitting into a conical hole in the centre of the plate, *f f*, and screwed to the box; a small endless screw, *h*, (*fig* 2.) turning in two brass collars screwed to the box, *b*, works in the teeth cut round the plate, *f*, and by that means when the milled head on the arbor of the endless screw is turned, it turns the eye-tube and box, D D, round, to bring it to any convenient position for measuring the angles required; the box containing the wires is shewn open in *fig.* 3, it containing two frames, *b b b* and *l l l l*, one sliding within another, which moves in the box, without lateral shake, yet fitted so as to slide easily backwards and forwards in the box, by the screws *m* and *n*, in the same manner as the microscope in the upper part of the same plate; *o* and *p* are springs to counteract the screws and make the motion pleasant. A wire is stretched across the frame, *b b*, at right angles to its sides, and another of the same size is fixed across the slider, *l l l l*, exactly parallel to the former; a small quantity of the under side of the latter is cut away, and its wire is fixed in another plane to the wire of *b b b*, so that the wires can pass each other without touching, but as near as possible; when they are placed by their screws over each other, and viewed through the eye-tube, they appear but as one wire: the divided circle, *x*, on the nuts of screws are then slipped round, without the screw, to bring the first division on them to the index *l*; the instrument is now adjusted for observing any angle, it is screwed to the telescope, and by the endless screw, *h*, (*fig.* 2.) the micrometer is turned round so as to bring a fixed wire *w*, which is perpendicular to the others, to cover the two objects; the two wires are then separated by turning either of the nuts, F, until the wires include the angle to be measured: the whole box (*fig.* 3.) of the micrometer slides through the tube, in the direction of its length, to follow any moving object. When the observation is completed it is read off by a scale of notches in the box, (*fig.* 3.) determining the number of revolutions the screw has made, and the divisions pointed out on the circles, *x*; by the indexes, *l*, *l*, the number of aliquot parts is denoted; the circular plate, *f f*, is divided into degrees, as shewn in *fig.* 2, and it is by this that the angle line measured makes with the horizon is registered.

The circles are divided in one hundred parts, and have no determinate value in angular measurement, but their value is determined experimentally by observing through the telescope, it is applied to the diameter of the sun, or any other body whose angular measure has been previously and accurately determined by some other divided instrument,

and

and from this the angle given by each obſervation is calculated.

Mr. Cavallo has contrived a micrometer of very ſimple and eaſy conſtruction. It conſiſts of a ſmall ſemi-tranſparent ſcale or ſlip of mother-of-pearl, about the 20th part of an inch broad, and of the thickneſs of common writing paper. It is divided into a number of equal parts by means of parallel lines, every fifth and tenth of which diviſions is a little longer than the reſt.

This micrometer, or divided ſcale, is ſituated within the tube at the focus of the eye-lens of the teleſcope, where the image of the object is formed, and with its divided edge paſſing through the centre of the field of view; though this is not abſolutely neceſſary. It is immaterial whether the teleſcope be a refractor or a reflector, provided the eye-lens be convex, and not concave, as in the Galilean teleſcope.

The ſimpleſt way of fixing it, is to ſtick it upon the diaphragm, which generally ſtands within the tube, at the focal diſtance of the eye-lens.

By looking through the teleſcope, the image of the object and the micrometer will appear to coincide: hence the obſerver may eaſily ſee how many diviſions of the latter meaſure the length or breadth of the former; and knowing the value of the diviſions of the micrometer, he may eaſily determine the angle which is ſubtended by the object.

There are ſeveral methods of aſcertaining the value of the diviſions of a micrometer in a given teleſcope. The following is one of the eaſieſt.

Direct the teleſcope to the ſun, and obſerve how many diviſions of the micrometer meaſure its diameter exactly; then take out of the Nautical Almanack the diameter of the ſun for the day in which the obſervation is made; divide it by the above-mentioned number of diviſions, and the quotient is the value of one diviſion of the micrometer. Thus, ſuppoſe that $26\frac{1}{2}$ diviſions of the micrometer meaſure the diameter of the ſun, and the Nautical Almanack gives for the meaſure of the angle, which is ſubtended by the ſame diameter, $31' 22''$, or (by reducing it all into ſeconds) $1882''$. Divide $1882''$ by 26.5, and the quotient, neglecting a ſmall remainder, is $71''$, or $1' 11''$; which is the value of one diviſion of the micrometer; the double of which is the value of two diviſions; the treble is the value of three diviſions; and ſo forth.

This mother-of-pearl micrometer may be applied to a microſcope; and it will thus ſerve to meaſure the lineal dimenſions of the object; and the value of its diviſions are aſcertained by placing an object of a known dimenſion before the microſcope, and by obſerving how many diviſions of the micrometer meaſure its magnified image; for inſtance, place a piece of paper, which is exactly one-tenth of an inch long, before the microſcope, and if you find that 50 diviſions of the micrometer meaſure its magnified image, you way conclude that each diviſion is equal to, or rather denotes an extenſion of the 500dth part of an inch in the object; for if 50 diviſions meaſure one-tenth, 500 diviſions muſt meaſure the whole inch; &c. Cavallo's Philoſophy, vol. iii. Phil. Tranſ. vol. lxxxi. art. 19.

The micrometer has not only been applied to teleſcopes, and employed for aſtronomical purpoſes; but there have been various contrivances for adapting it to microſcopical obſervations. M. Leeuwenhoek's method of eſtimating the ſize of ſmall objects was by comparing them with grains of ſand, of which a hundred in a line took up an inch. Theſe grains he laid upon the ſame plate with his objects, and viewed them at the ſame time. Dr. Jurin's method was ſimilar to this; for he found the diameter of a piece of fine ſilver wire, by wrapping it as cloſe as he could about a pin, and obſerving how many rings made an inch; and he uſed this wire in the ſame manner as Leeuwenhoek uſed his ſand. Dr. Hooke uſed to look upon the magnified object with one eye, while, at the ſame time, he viewed other objects, placed at the ſame diſtance, with the other eye. In this manner he was able, by the help of a ruler, divided into inches and ſmall parts, and laid on the pedeſtal of the microſcope, to caſt, as it were, the magnified appearance of the object upon the ruler, and thus exactly to meaſure the diameter which it appeared to have through the glaſs; which being compared with the diameter as it appeared to the naked eye, eaſily ſhewed the degree in which it was magnified. A little practice, ſays Mr. Baker, will render this method exceedingly eaſy and pleaſant.

Mr. Martin, in his Optics, recommends ſuch a micrometer for a microſcope as had been applied to teleſcopes; for he adviſes to draw a number of parallel lines on a piece of glaſs with the fine point of a diamond, at the diſtance of $\frac{1}{40}$th of an inch from one another, and to place it in the focus of the eye-glaſs. By this method, Dr. Smith contrived to take the exact draught of objects viewed by a double microſcope; for he adviſes to get a lattice, made with ſmall ſilver wires or ſquares, drawn upon a plain glaſs by the ſtrokes of a diamond, and to put it into the place of the image formed by the object-glaſs. Then by transferring the parts of the object, ſeen in the ſquares of the glaſs or lattice, upon ſimilar correſponding ſquares drawn on paper, the picture may be exactly taken. Mr. Martin alſo introduced into compound microſcopes another micrometer conſiſting of a ſcrew. See both theſe methods deſcribed in his Optics, p. 277.

The moſt minute and accurate diviſion of any ſcale which the editor has ever ſeen, was performed by Mr. Coventry of Southwark. The micrometers of his conſtruction are parallel lines drawn on glaſs, ivory, or metal, from the 10th to the 10,000dth of an inch. Theſe may be applied to microſcopes, for meaſuring the ſize of minute objects, and the magnifying power of the glaſſes; and to teleſcopes, for meaſuring the ſize and diſtance of objects, and the magnifying power of the inſtrument. For meaſuring the ſize of an object in a ſingle microſcope, lay it on a micrometer, whoſe lines are ſeen magnified in the ſame proportion with it, and give at one view the real ſize of the object. For meaſuring the magnifying power of the compound microſcope, the beſt and moſt ready method is the following. On the ſtage in the focus of the object-glaſs, lay a micrometer, conſiſting of an inch divided into one hundred equal parts; count how many diviſions of the micrometer are taken into the field of view; then lay a two-foot rule parallel to the micrometer: fix one eye on the edge of the field of light, and the other eye on the end of the rule, which move, till the edge of the field of light and the end of the rule correſpond; then the diſtance from the end of the rule to the middle of the ſtage will be the half of the diameter of the field: *e. gr.* if the diſtance be ten inches, the whole of the diameter will be twenty, and the number of the diviſions of the micrometer contained in the diameter of the field, is the magnifying power of the microſcope. Thus, ſuppoſe the number of diviſions ſeen in the micrometer to be $\frac{50}{100}$dths, and that the diameter of the field meaſures with the rule twenty inches; the $\frac{50}{100}$dth of 20 inches is 40, which is the diameter of the field; $40 \times 40 = 1600$ the ſuperficies, and $1600 \times 40 = 64000$, the magnified cube of the object: in like manner each object-glaſs or magnifier muſt be proved, and a table kept of their ſeveral magnifying powers. For meaſuring the height and diſtance of objects by a micrometer in in the telescope, see TELESCOPE. Mr. Adams has applied a micrometer, which instantly shews the magnifying power of any telescope.

MICROPHONES, instruments contrived to magnify small sounds, as microscopes do small objects.

MICROPUS, in *Botany*, derived from μικρος, *small*, and πους, *a foot;* possibly from an association of ideas with *Leontopodium*, Lion's-foot, as this genus is nearly assimilated in habit to the *Filago Leontopodium* of Linnæus. It was even supposed by Dr. Sibthorp to be the real Λεοντοποδιον of Dioscorides; (see LEONTOPODIUM.)—Linn. Gen. 451. Schreb. 588. Willd. Sp. Pl. v. 3. 2388. Mart. Mill. Dict. v. 3. Ait. Hort. Ord. *Compositæ Nucamentaceæ*, Linn. *Corymbiferæ*, Juss.

Gen. Ch. *Common calyx* double; the outer of five, slender, small, obsolete leaves, at the base of the inner, which is very large, and composed of five, loose, distinct, helmet-shaped, compressed leaves, conniving longitudinally at the margin. *Cor.* compound, with ten perfect florets in the disk, and five female ones in the radius: the former of one petal, with five teeth, erect; the latter without any petal. *Stam.* (in the perfect florets) Filaments five, bristle-shaped, very short; anthers cylindrical, tubular, as long as the florets. *Pist.* (in the same florets) Germen obsolete; style thread-shaped, longer than the stamens; stigma obsolete: (in the female ones) Germen obovate, compressed, concealed within each scale of the common inner calyx; style from the inner side of the germen, bristle-shaped, turned towards the perfect florets, the length of the calyx; stigma cloven, slender, pointed. *Peric.* none, except the common inner calyx enlarged and hardened. *Seeds* (in the perfect flowers) none: (in the female ones) solitary, obovate, inclosed each in its appropriate leaflet of the inner calyx. *Recept.* furnished with acute, small scales, which separate the seeds of the females, but not the florets of the disk.

Ess. Ch. Receptacle scaly. Down none. Calyx double. Radius without a corolla. Female florets inclosed by the scales of the common inner calyx.

1. M. *supinus*. Linn. Sp. Pl. 1313. Cavan. Ic. v. 22. t. 35.—Stems prostrate. Leaves opposite, obovate-wedge-shaped.—A native of Portugal, Spain, Italy, and the Levant, flowering from May to September. Introduced into Chelsea garden in 1759, by Mr. Philip Miller.—*Root* annual, somewhat tapering, small, fibrous. *Stems* trailing, numerous, three or four inches long, covered with a sort of silvery nap, as indeed is the whole plant. *Leaves* in pairs, generally opposite, or nearly so, connate, plaited, three-nerved. *Flowers* axillary, sessile, from the base to the top of the stem, minute, in small tufts, white and very downy. *Seeds* ovate, brown.

2. M. *erectus*. Linn. Sp. Pl. 1313. Lœfl. It. Hisp. 166. t. 1. f. 5.—Stems upright. Leaves alternate, lanceolate.—A native of the East, as well as of France, Italy, and Switzerland.—*Root* annual, fibrous. *Stems* erect, branched, extremely downy. *Leaves* alternate, narrower and more woolly than in the last, as is the whole plant, even the *flowers* which are sessile, in axillary tufts.

MICROSCOPE, Μικροσκοπειον, formed of μικρος, *small*, and σκεπτομαι, *I consider;* an optical instrument, by means of which very minute objects are represented exceedingly large, and viewed very distinctly, according to the laws of refraction or reflection.

Microscopes are properly distinguished into simple, or *single;* and compound, or *double*.

MICROSCOPES, *Single*, are those which consist of a single lens, or a single spherule.

MICROSCOPES, *Compound*, consist of two or more lenses duly combined. As optics have been improved, other varieties have been contrived, in the sorts of microscopes: hence we have *reflecting* microscopes, *water* microscopes, &c. Each of these two kinds has its peculiar advantage: for a single glass shews the object nearer at hand, and rather more distinct: and a combination of glasses presents a larger field, or, in other words, exhibits more of an object equally magnified, at the view. As each of these has its advantages, each of them has had its advocates, at least in practice. M. Leeuwenhoek never used any but single microscopes; and, on the contrary, Dr. Hooke made all his observations with double ones.

When, and by whom, microscopes were first invented, is not certainly known. Huygens tells us, that one Drebell, a Dutchman, had the first microscope, in the year 1621, and that he was reputed the first inventor of it: though F. Fontana, a Neapolitan, in 1646, claims the invention to himself, but dates it from the year 1618. As a telescope inverted is a microscope, the discovery might easily enough have arisen from thence.

Nothing more is certain concerning microscopes, than that they were first used in Germany about the year 1621. According to Borellus, they were invented by Zacharias Jansen, in conjunction with his son, who presented the first microscope they had constructed to prince Maurice, and Albert, archduke of Austria. William Borell, who gives this account in a letter to his brother Peter, says, that when he was ambassador in England, in 1619, Cornelius Drebell shewed him a microscope, which he said was the same that the archduke had given him, and had been made by Jansen himself. Borellus de vero Telescopii inventore, p. 35. See LENS.

MICROSCOPES, *Foundation and Theory of Single*. If an object A B (*Plate* XII. *Optics*, *fig.* 1.) be placed in the focus of a small convex lens, or a simple microscope D E, and the eye be applied close to the other side of the microscope, *the object will be seen distinct, in an erect situation, and magnified in the ratio of the distance of the focus to the distance at which objects are to be placed to be seen distinctly by the naked eye.*

For the object A B being placed in the focus of the convex lens D E, the rays issuing from the several points of it, after refraction, will be parallel to each other: consequently, the eye will see it *distinctly*, by virtue of what is proved under the word TELESCOPE.

Further, since one of the rays A F, proceeding from the point A, after refraction, becomes parallel to the incident ray; and therefore, setting aside the thickness of the lens, is found directly against it; and the same holds true of all the other rays carried to the eye; the rays A F and B F, to which the rest coming from A and B are parallel, will enter the eye in the same manner as if they entered without passing through the lens; and will therefore appear erect, as if the lens were away.

Lastly, it is manifest, that the object A B will be seen under the same angle as if viewed by the naked eye: but since it appears very distinct, whereas to the naked eye, at the same distance, it would appear extremely confused; it is the same thing as if the object should seem removed to the distance F H, at which it is viewed with equal distinctness, and under the same angle: the diameter of the object A B, therefore, will be to the apparent diameter I K, as F C to F H, *i. e.* as the distance of the focus of the lens to the distance at which an object is to be placed, in order to view it distinctly. Since, therefore, the interposition of the glass has

has no other effect than to render the appearance distinct, by helping the eye to increase the refraction of the rays in each pencil, it is plain that the greater apparent magnitude is entirely owing to a nearer view than could be taken by the naked eye.

Huygens, in Dioptrics, prop. lix. p. 222, takes it for granted, that an object, seen with the naked eye, is then in its utmost distinctness when seen at the distance of eight digits, or tenths of a foot; which agrees pretty nearly with the observations of others; who make the nearest limit of distinct vision to be eight inches. So that if the glass be a small round globule, whose focal distance is $\frac{1}{20}$th of an inch, this globule will magnify as 8 to $\frac{1}{20}$th, or as 160 to 1.

The distance of distinct vision varies in different individuals. Some have stated it at six inches; others at seven; but it has been generally supposed to be eight inches. The medium of seven inches has been adopted by several optical writers. But whatever it be, if this least distance be divided by the focal distance of the glass, the quotient will shew how much the glass magnifies the diameter of the object.

MICROSCOPES, *Laws of Single.* 1. Simple microscopes magnify the diameter of the object A B in the ratio of the distance of the focus F C to an interval of eight digits: *v. gr.* if the semi-diameter of a lens, equally convex on both sides, be half a digit, and consequently its focal distance the same; A B : I K :: $\frac{1}{2}$: 8 :: 1 : 16; that is, the diameter of the object will be increased in a sedecuple proportion, or as sixteen to one. 2. Since the distance F H is constant, *viz.* eight digits; by how much the distance of the focus F C is smaller, so much the smaller ratio will it have to F H; consequently the diameter of the object will be so much the more magnified. 3. Since, in plano-convex lenses, the distance of the focus is equal to the diameter; and, in lenses equally convex on both sides, to the semi-diameter: simple microscopes will enlarge the diameter so much the more, as they are segments of smaller spheres. 4. If the diameter of the convexities of a plano-convex lens, and a lens convex on both sides, be the same, *viz.* = 1: the distance of the focus of the first will be 1, of the second $\frac{1}{2}$: consequently, the semi-diameter of the object A B will be to the apparent one, in the first case, as 1 to 8; in the latter, as $\frac{1}{2}$ to 8; *i. e.* as 1 to 16. A lens, therefore, convex on both sides, magnifies twice as much as a plano-convex lens.

As the whole depends on the just and steady situation of objects with regard to the lens, various methods have been contrived to that end; whence we have several different kinds of single microscopes. The most simple is as follows:

1. A B (*fig.* 2.) is a little tube, to one of whose bases, B C, is fitted a plain glass, to which an object, *viz.* a gnat, wing of an insect, down, or the like, is applied; to the other base, A D, at a proper distance from the object, is applied a lens convex on both sides, whose semi-diameter is about half an inch; the plain glass is turned to the sun, or the light of a candle, and the object is seen magnified; and, if the tube be made to draw out, lenses of different spheres may be used.

Again, a lens, convex on both sides, is inclosed in a cell A C (*fig.* 3.), and by a screw H is there fastened: through the pedestal C D passes a long screw, by means of which, and the female screw I, a style or needle, fixed perpendicular to its extreme, is kept firm at any distance from the lens: in E is a little tube, on which, and on the point G, the various objects are to be disposed: thus there may be lenses of various spheres applied.

2. But the microscope which is found to answer the end best, is Mr. Wilson's pocket microscope, which has nine different magnifying glasses, eight of which may be used with two different instruments, for better applying them to various objects. One of these instruments is represented at A A B B (*fig.* 4.) and is made of ivory, brass, or silver; it has three thin brass plates at E, and a spiral spring of steel wire H within it; to one of the thin plates of brass is fixed a piece of leather, wood, or ivory F, with a small furrow, G, both in the leather and brass to which it is fixed: in one end of this instrument there is a long screw D, with a convex glass placed in the end of it at C: in the other end, A A, of the instrument there is a hollow screw, in which any of the magnifying glasses, M, are screwed when they are to be made use of. The nine different magnifying glasses are all set in ivory, eight of which are set in the manner expressed at M. The greatest magnifier is marked upon the ivory, in which it is set, with N° 1, the next N° 2, and so on to N° 8; the ninth glass is not marked, but is set in the manner of a little barrel box of ivory, as at *b*, *fig.* 5. R is a flat piece of ivory, of which there are eight belonging to this set of microscopes (though any one who has a mind to keep a register of objects may have as many of them as he pleases); in each of them there are four holes *f, f, f*, in which four or more objects are placed between two thin glasses, or talcs, when they are to be used with the greater magnifiers.

The use of this instrument A A B B is this. Having taken the handle W from the instrument in *fig.* 5, and screwed it upon the button S, take one of your flat pieces of ivory, R, or sliders (if you please to call them so), and slide it betwixt the two thin plates of brass at E, through the body of the microscope, so that the object you intend to look upon be just in the middle; remarking that you put that side of the plate R, where the brass rings are, farthest from the end A A; then you are to screw into the hollow screw in the end A A of the body of your microscope M, the 3d, 4th, 5th, 6th, or 7th magnifying glass; which being done, put the end A A close to your eye, and while you are looking through your magnifying glass upon the object, you are to screw in or out the long screw D, which moving round upon the leather F, held tight to it by the spiral wire H, will bring your object to the true distance; which you will know by seeing it clearly and distinctly: but since in the greater magnifiers you can see but a small part of the object, *viz.* the legs or claws of a flea; while you are looking upon any part of the object, if you take hold of the end of the plate or slider R, on which the object lies, and move it gently, you may see the whole object successively, or any part of the object you please; and if that part of the object you design to look upon be out of the true distance, remember your end screw, D, can always bring it in, by screwing it one way or the other. A simpler and more convenient method of mounting single microscopes is to fix the several magnifying lenses in a flat circular piece of brass, which can be moved round a point as a centre, by the action of an endless screw upon the toothed circumference of the circular plate.

After this manner may be seen all transparent objects, dusts, liquids, crystals of salts, small insects, such as fleas, mites, &c. If they be insects that will creep away, or such objects as one intends to keep, they may be placed between the two register glasses *f, f*. For by taking out (with the point of a pen-knife or small plyers) the ring that keeps in the glasses *f, f*, where the object lies, they will fall out of themselves; so that you may lay the object between the two hollow sides of them, and put the ring in as it was before: but if the objects be dusts or liquids, a small drop of the liquid, or

a little

a little of the duſt laid on the outſide of the glaſs *ff*, and applied as before, will be ſeen very eaſily.

As to the firſt, ſecond, and third magnifying glaſſes, being marked with a + upon the ivory in which they are ſet, they are only to be uſed with thoſe plates or ſliders that are alſo marked with a +, in which the objects are placed between two thin talcs; becauſe the thickneſs of the glaſſes in the other plates or ſliders, hinders the object from approaching to the true diſtance from theſe greater magnifiers. But the manner of uſing them is the ſame with the former: only remember to be careful when you put in or pull out the plate or ſlider R, on which the object lies, or move it from one object to another, not to let it rub your magnifying glaſs; which is done by unſcrewing a little the end ſcrew D, when you put in or pull out your plate, or move it from one object to another.

For ſeeing the circulation of the blood at the extremities of the arteries and veins, in the tranſparent parts of fiſhes' tails, &c. there are two ſhort glaſs tubes, the one bigger and the other leſſer, in which the fiſh is to be put; when theſe tubes are to be uſed, you are to unſcrew the end ſcrew D in the body of the microſcope, until the glaſs tube can be received eaſily into that little cavity G of the braſs plate faſtened to the leather F, under the other two thin plates of braſs at E. When the tail of your fiſh lies flat to the glaſs tube, ſet it oppoſite to your magnifying-glaſs, and by ſcrewing in or out your end ſcrew D, as is ſaid before, you may eaſily bring it to the true diſtance, and ſee the blood circulate with great pleaſure.

If you would ſee the blood circulate in a frog's foot, chooſe ſuch a frog as will juſt go into your tube; then with a little ſtick expand the hinder foot of the frog, and apply it cloſe to the ſide of the tube, obſerving that no part of the frog hinders the light from coming on its foot; and when you have it at the juſt diſtance, by means of the ſcrew D, as above ſaid, you will ſee the rapid motion of the blood in its veſſels, which are very numerous, in the tranſparent thin membrane that is between the frog's toes. For this object the fourth and fifth magnifiers will do very well; but you may ſee the circulation in the tails of water-newts with the fixth and ſeventh glaſſes, becauſe the globules of the blood of thoſe newts are as big again as the globules of the blood of frogs or ſmall fiſh, as has been taken notice of in N° 280 of the Philoſophical Tranſactions, p. 1184.

The circulation cannot ſo well be ſeen by the firſt, ſecond, and third magnifiers, becauſe the thickneſs of the glaſs tube in which the fiſh lies, hinders the approach of the object to the focus of the magnifying glaſs.

The other inſtrument (*fig.* 5.) is made of braſs or prince's metal, with joints P, P, P, to turn eaſily any way, and with a ſmall pair of tongs G G, which open at the points K, by preſſing together the two heads of the pins I, I, for taking up of objects. At the other end of theſe tongs G G, is ſcrewed on a round piece of black wood H, with a piece of ivory let into it, for placing opaque objects on, according to their difference of colour. Upon the end L there is a ſcrew, upon which the glaſs *b* ſet in the barrel-box may be ſcrewed. When the other glaſſes are to be uſed, there is a ring R of braſs to be ſcrewed on the end L, into which ring all the other glaſſes, M, (*fig.* 4.) may be ſcrewed. So when any object is taken up in the points of the tongs K, or laid upon the other end H, it may very eaſily (as one who ſees the inſtrument will perceive) be applied to the true focal diſtance of any of the glaſſes M, by the help of the joints P, P, P, and by means of the ſcrew C, with the nut D, which being regulated by a ſpring N, will bring the object to the exact diſtance for diſtinct viſion.

The glaſs placed in the manner of a barrel-box at *b*, is only to be uſed with the braſs inſtrument (or in your hand) being the leaſt magnifier for greater objects, ſuch as fleas and common inſects, &c. remembering to put the hole at *b* next to your eye.

In the viewing of objects, one ought to be careful not to hinder the light from falling on them, by the hat, peruke, or any other thing, eſpecially in looking at opaque objects; for nothing can be ſeen with the beſt of glaſſes, unleſs the object be at a due diſtance, with a ſufficient light. The beſt lights for the plates or ſliders, where the object lies between the two glaſſes, is a clear ſky-light, or where the ſun ſhines on any white thing, or the reflexion of the light from a looking-glaſs. The light of a candle is likewiſe good for the viewing of very ſmall objects, though it be a little uneaſy to thoſe who are not practiſed in microſcopes to find it out. The only uſe of the convex lens at C (*fig.* 4.) is to collect the light into a narrower compaſs where it falls upon the object, after it has paſſed through a moderate hole in the leather F.

For the convenience of thoſe who would draw, or make any ſketches or deſigns of microſcopical objects, they may alſo have a pedeſtal to fix the two inſtruments above deſcribed, and make them ſtationary to any convenient light. This pedeſtal may be placed on a table, and after the object and ſight are fixed, as many perſons as pleaſe may view the object without any trouble or difficulty in finding the light. (Phil. Tranſ. abr. vol. iv. p. 199, &c.) Mr. Baker in his treatiſe "Of Microſcopes," (vol. i.) has deſcribed an invention for fixing the pocket microſcope of Wilſon, and giving light to it by a ſpeculum. For this purpoſe a ſcroll of braſs is fixed upright and ſteady on a round pedeſtal of wood. A braſs ſcrew is made to paſs through a hole in the upper limb of the ſcroll into the ſide of the microſcope, ſo as to ſcrew it faſt to the ſcroll. On the pedeſtal is fixed an arch, in which a concave ſpeculum, ſet in a box of braſs, is ſuſpended by means of two ſmall ſcrews, that faſten to its oppoſite ſides. As the arch turns on the pin by which it is fixed to the pedeſtal, and the ſpeculum turns within the arch, it may, by this twofold motion, be eaſily adjuſted in ſuch a manner as to reflect the light of the ſky, the ſun, or a candle, directly upwards, through the microſcope that is fixed perpendicularly over it; and by ſo doing, may anſwer almoſt all the purpoſes of the large double reflecting microſcope. The body of the microſcope may alſo be fixed horizontally, and objects may be viewed from that poſition, by any light you chooſe; which is an advantage that does not belong to the reflecting microſcope. It may be alſo rendered further uſeful, by means of a ſlip of glaſs, one end of which being thruſt between the plates where the ſliders go, and the other extending to ſome diſtance, ſuch objects may be placed upon it as cannot be applied on the ſliders; and then, having a limb of braſs that may faſten to the body of the microſcope, and extend over the projecting glaſs a hollow ring on which to ſcrew the magnifiers, all ſorts of ſubjects may be examined with great convenience, if a hole be made in the pedeſtal to place the ſpeculum exactly underneath, and thereby throw up the rays of light. What has been ſaid hitherto, is to be underſtood of *lenticular* microſcopes; as for *ſpherical* ones, their doctrine will be underſtood from what follows.

If an object A B (*fig.* 6.) be placed in the focus of a glaſs ſpherule F, and the eye be behind it, *v. gr.* in the focus G; the object will be ſeen diſtinct, in an erect ſituation, and magnified, as to its diameter, in a ratio of $\frac{3}{4}$ths of the diameter E I, to the diſtance at which objects are to be placed to be ſeen diſtinctly with the naked eye.

 The

The firſt part of the propoſition is proved in the ſame manner of ſpheres, as of lenſes. As, then, a good eye ſees an object diſtinctly at the diſtance of eight digits, a glaſs ſpherule will enlarge the diameter of an object in a ratio of $\frac{3}{4}$ths of the diameter to eight digits. Suppoſe, then, the diameter of the ſpherule E $\frac{1}{10}$th of a digit, C E will be $= \frac{1}{20}$, and F E $= \frac{1}{40}$; and therefore F C $= \frac{1}{20} + \frac{1}{40} = \frac{3}{40}$. Conſequently, the true diameter of an object to its apparent one is in the ratio of $\frac{3}{40}$ to 8; *i.e.* as 3 to 320, or as 1 to 106 nearly.

Now a lens, convex on both ſides, increaſes the diameter in a ratio of the ſemidiameter to the ſpace of eight digits; wherefore $\frac{1}{2}$ having a leſs ratio to eight than $\frac{3}{4}$ths, if a lens and a ſphere have the ſame diameter, the former will magnify more than the latter; and, pretty much after the ſame manner, it may be ſhewn, that a ſphere, of a leſs diameter, magnifies more than another of a large one.

As for the methods of caſting little glaſs ſpherules for microſcopes, they are various. The firſt perſon who improved ſingle microſcopes by uſing ſmall globules of glaſs, made by melting them in the flame of a candle, was Hartſocker, who thus diſcovered the animalcula in ſemine maſculino, and laid the foundation of a new ſyſtem of generation. Wolfius deſcribes the following method of making globules of this kind; a ſmall piece of very fine glaſs, ſticking to the wet point of a ſteel needle, is to be applied to the extreme blueiſh part of the flame of a lamp, or, which is better, to the flame of ſpirit of wine, to prevent its being blackened: being there melted and run into a little round drop, it is to be removed from the flame, upon which it inſtantly ceaſes to be fluid; folding, then, a thin plate of braſs, and making very ſmall ſmooth perforations, ſo as not to leave any roughneſs on the ſurfaces; and, farther, ſmooth them over, to prevent any glaring, fit the ſpherule between the plates againſt the apertures, and put the whole in a frame, with objects convenient for obſervation.

Mr. Adams gives another method, thus: take a piece of fine window-glaſs, and raiſe it, with a diamond, into as many lengths as you think needful, not exceeding an eighth of an inch in breadth; then holding one of thoſe lengths between the fore-finger and the thumb of each hand, over a very fine flame, till the glaſs begins to ſoften, draw it out till it be as fine as a hair, and break; then, applying each of the ends into the pureſt part of the flame, you have two ſpheres preſently, which you may make larger, or leſs, at pleaſure: if they ſtay long in the flame, they will have ſpots; ſo they muſt be drawn out immediately after they are turned round. As to the ſtem, break it off as near the ball as poſſible; and, lodging the remainder of the ſtem between the plates, by drilling the hole exactly round, all the protuberances are buried between the plates; and the microſcope performs to admiration.

Mr. Butterfield, in the Phil. Tranſ. N° 141, recommends, for making glaſs globules clear and without ſpecks, the flame of a lamp, made with rectified ſpirit of wine, and inſtead of a cotton wick, fine ſilver-wire, doubled like a ſkain of thread; then having beaten ſome fine glaſs to powder, and waſhed it clean, he directs to take a little of it upon the ſharp point of a ſilver needle, wetted with ſpittle, and to hold it in the flame, turning it about till it melts, and becomes quite round. When many globules are thus formed, he rubs them with ſoft leather; and having ſeveral ſmall pieces of thin braſs plates, twice as long as they are broad, he doubles them up into the form of a ſquare, and puſhes a fine hole through the middle of them, and having rubbed off the bur about the holes with a whetſtone, and blackened the inſide of the plates with the ſmoke of a candle, he places a globule between the two holes, and tacks the plates together with two or three rivets.

Dr. Hooke uſed to take a very clear piece of glaſs, and to draw it out into long threads in a lamp; then he held theſe threads in the flame, till they ran into round globules hanging to the end of the threads. Then having fixed the globules with ſealing-wax to the end of a ſtick, ſo that the threads ſtood upwards, he ground off the ends of the threads upon a whetſtone, and poliſhed them upon a ſmooth metal plate with a little putty. Mr. Stephen Gray tells us, (Phil. Tranſ. N° 221. 223.) that for want of a ſpirit lamp, he laid a ſmall particle of glaſs, about the ſize of the intended globule, upon the end of a piece of charcoal; and by means of a blaſt-pipe, with the flame of a candle, he ſoon melted it into a globule. He thus made them indifferently clear, and the ſmalleſt very round; but the larger by reſting upon the coal were a little flattened, and became rough on that ſide. He therefore ground and poliſhed them upon a braſs plate, till he reduced them to hemiſpheres. But he found that the ſmall round globules not only magnified more, but ſhewed objects more diſtinct than the hemiſpheres.

By theſe methods may ſpheres be made much ſmaller than any lens; ſo that the beſt ſingle microſcopes, or thoſe which magnify the moſt, are made of them. For ſuppoſe the diameter of a ſpherule to be $\frac{1}{16}$ of a digit, the diſtance of its focus will be $\frac{1}{64}$; and therefore its real diameter to its apparent one, as $\frac{1}{32} + \frac{1}{64}$; that is, as $\frac{3}{64}$ to 8, or as 3 to 512; or, laſtly, as 1 to 170. The ſurface of an object, therefore, will be increaſed by it in the proportion of 1 to 28900, and its bulk in a ratio of 1 to 4913000.

Mr. Leeuwenhoek and M. Muſchenbroek have ſucceeded very well in ſpherical microſcopes; and the apparatus of the latter is much commended; but we forbear any deſcriptions of them; it being eaſy for any one who conſiders the ſtructure of thoſe conſiſting of lenſes, to conceive how thoſe of ſpheres may be contrived.

Mr. Leeuwenhoek's microſcopes were all ſingle ones; each of them conſiſting of a ſmall double convex glaſs ſet in a ſocket, between two ſilver plates, riveted together, and pierced with a ſmall hole; and the object was placed on the point of a needle, ſo contrived, as to be placed at any diſtance from the lens. If the objects were ſolid, he faſtened them with glue; and if they were fluid, or, on other accounts, required to be ſpread on glaſs, he placed them on a ſmall piece of Muſcovy talc, or glaſs blown very thin, which he afterwards glued to his needle. He had however a different apparatus for viewing the circulation of the blood, which he could fix to the ſame microſcopes. Thoſe which he bequeathed to the Royal Society were contained in a ſmall Indian cabinet, in the drawers of which were thirteen little boxes or caſes, in each of which were two microſcopes, neatly fitted up in ſilver; and both the glaſs and the apparatus were made with his own hands. The greateſt magnifier among theſe enlarged the diameter of an object about 160 times Phil. Tranſ. Abr. vol. vi. p. 129, &c. Id. vol. viii. p. 121, &c.

Several writers, ſays Mr. Baker (ubi infra) have repreſented the glaſſes uſed by Mr. Leeuwenhoek in his microſcopes, to be little globules or ſpheres of glaſs; but he aſſures us, from an inſpection of his cabinet, that every one of the 26 microſcopes contained in it, was a double convex lens, and not a ſphere or globule.

The ſmalleſt globules, and conſequently the greateſt magnifiers for microſcopes that have yet been executed, were made by F. Di Torre of Naples, who, in 1765, ſent four of them to the Royal Society. The largeſt of them was only

only two Paris points in diameter, and is ſaid to magnify the diameter of an object 640 times; the ſecond was the ſize of one Paris point; magnifying the diameter 1280 times, and the third no more than one-half of a Paris point, or the 144th part of an inch in diameter, and was ſaid to magnify the diameter of an object 2560 times, and conſequently the ſquare of ſuch a diameter 6,553,600 times. But ſince the focus of a glaſs globule is at the diſtance of one-fourth of its diameter, and, therefore, that of the third globule of Di Torre, above mentioned, only the 576th part of an inch diſtant from the object, it muſt be with the utmoſt difficulty that globules ſo minute as theſe can be employed to any purpoſe; and Mr. Baker, to whoſe examination they were referred, conſiders them as matters of curioſity rather than of real uſe. (Phil. Tranſ. vol. lv. p. 246. vol. lvi. p. 67, &c.) For an account of obſervations made with theſe globules on the blood, ſee Blood.

Experience, ſays Mr. Baker, in his treatiſe "Of Microſcopes," has taught us, that thoſe globules which were at firſt highly extolled and much ſought after, admit ſo little light, can ſhew only ſuch an exceeding minute part of any object, are ſo difficult to be uſed, and ſtrain the eyes ſo much, that their power of magnifying, for want of due diſtinctneſs, is rather apt to produce error than to diſcover truth, and therefore now they are very rarely employed.

In order to ſtate clearly and diſtinctly the method of determining the magnifying powers of glaſſes employed in ſingle microſcopes, we ſhall obſervo, that if the focus of a convex lens (*e. g.*) be at one inch, and the natural ſight at eight inches, which is the common ſtandard, an object may be ſeen through that lens at one inch diſtant from the eye; and will appear, in its diameter, eight times larger than to the naked eye. But as the object is magnified every way equally, in length as well as breadth, we muſt ſquare this diameter, to know really how much it appears enlarged; and we ſhall then find, that its ſuperficies is indeed magnified ſixty-four times.

Again: ſuppoſe a convex lens whoſe focus is at one-tenth of an inch diſtant from its centre: in eight inches there are eighty ſuch tenths of an inch; and therefore an object may be ſeen through this lens eighty times nearer than it can diſtinctly by the naked eye. It will conſequently appear eighty times longer, and eighty times broader, than it does to common ſight; and as eighty multiplied by eighty makes ſix thouſand and four hundred, ſo many times it really appears magnified.

To go one ſtep farther: if a convex glaſs be ſo ſmall, that its focus is no more than one-twentieth of an inch diſtant; we ſhall find that eight inches, the common diſtance of ſight, contains an hundred and ſixty of theſe twentieth parts; and, in conſequence, the length and breadth of an object, when ſeen through ſuch lens, will each be magnified an hundred and ſixty times; which multiplied by an hundred and ſixty, to give the ſquare, will amount to twenty-five thouſand ſix hundred; and ſo many times, it is plain, the ſuperficies of the object muſt appear larger than it does to the naked eye at the diſtance of eight inches.

Therefore, in a ſingle microſcope, to learn the magnifying power of any glaſs, no more is neceſſary than to bring it to its true focus; the exact place of which will be known, by an object's appearing perfectly diſtinct and ſharp when placed there. Then, with a pair of ſmall compaſſes, meaſure, as nearly as you can, the diſtance from the centre of the glaſs to the object you were viewing, and afterwards applying the compaſſes to any ruler with a diagonal ſcale of the parts of an inch marked on it, you will eaſily find how many parts of an inch the ſaid diſtance is. When that is known, compute how many times thoſe parts of an inch are contained in eight inches, the common ſtandard of ſight, and that will give you the number of times the diameter is magnified: ſquaring the diameter will give you the ſuperficies; and if it be an object whoſe depth or whole contents you would learn, multiplying the ſuperficies by the diameter will ſhew the cube or bulk.

A Table of the Magnifying Powers of Convex Glaſſes, employed in Single Microſcopes, according to the Diſtance of their Focus: Calculated by the Scale of an Inch divided into an Hundred Parts: Shewing how many Times the Diameter, the Superficies, and the Cube of an Object is magnified, when viewed through ſuch Glaſſes, to an Eye whoſe natural Sight is at Eight Inches, or Eight Hundred of the Hundredth Parts of an Inch.

		Hundred parts of an inch:	Magnifies the Diameter.	Magnifies the Superficies.	Magnifies the Cube of an Object.

N.B. The

N.B. The greateft magnifier in Mr. Leeuwenhoek's Cabinet of Microfcopes, prefented to the Royal Society, has its focus, as nearly as can well be meafured, at $\frac{1}{20}$th of an inch diftance from its centre, and confequently magnifies the diameter of an object 160 times, and the fuperficies 25,600. But the greateft magnifier in Mr. Wilfon's fingle microfcopes, as they are now made, has ufually its focus at no farther diftance than about the fiftieth part of an inch; whereby it has the power of enlarging the diameter of an object 400, and its fuperficies 160,000 times.

The following Table is calculated on the fuppofition that the neareft diftance at which we can fee diftinctly is feven inches; and fhews the magnifying power of fmall convex lenfes or fingle microfcopes, not exceeding an inch in focal length.

Focal Diftance of the Lens or Microfcope.		Number of Times that the Diameter of an Object is magnified.		Number of Times that the Surface of an Object is magnified.	Number of Times that the Cube of an Object is magnified.

Ferguson's Mechanics by Brewfter, vol. ii. p 449.

Microscope, *Water*. Mr. S. Gray, and, after him, Wolfius, and others, have contrived water microfcopes, confifting of fpherules, or lenfes of water, inftead of glafs, fitted up fomewhat after the manner of thofe above mentioned (as fpheres of water may be likewife ufed inftead of glafs in any of the common microfcopes.) But fince the diftance of the focus of a lens or fphere of water is greater than that of one of glafs (the fpheres whereof they are fegments being the fame), water microfcopes magnify lefs, and are therefore lefs efteemed than thofe of glafs. The fame Mr. Gray firft obferved, that a fmall drop or hemifpherule of water, held to the eye by candlelight or moonlight, without any other apparatus, magnified the animalcula contained in it vaftly more than any other microfcope. The reafon is, that the rays, coming from the interior furface of the firft hemifphere, are reflected fo as to fall under the fame angle on the furface of the hind hemifphere, to which the eye is applied, as if they came from the focus of the fpherule; whence they are propagated to the eye in the fame manner as if the objects were placed without the fpherule in its focus. Phil. Tranf. N° 221. 223. Smith's Optics, vol. ii. p. 334, &c.

Hollow glafs fpheres, of the diameter of about half a digit, filled with fpirit of wine, are frequently ufed for microfcopes: but they do not magnify near fo much.

Dr. Brewfter, in the Appendix to his edition of Ferguson's Mechanics, &c., defcribes a microfcope totally different from that of Mr. Gray, though founded upon the fame general principle. Inftead of water, he makes ufe of very pure and vifcid turpentine, which he takes up by the point of a piece of wood, and drops fucceffively upon a thin and well polifhed glafs: different quantities being thus taken up and dropped in a fimilar manner form four or more plano-convex lenfes of turpentine varnifh, which may be made of any focal length, by taking up a greater or lefs quantity of the fluid. The lower furface of the glafs having been firft fmoaked with a candle, the black pigment below the lenfes is then to be removed, fo that no light may pafs by their circumference. The piece of glafs is then to be perforated, and furrounded with a toothed wheel, which can be moved round the hole as a centre by an endlefs fcrew. The apparatus is then placed in a circular cafe, and this cafe fixed to an horizontal arm by means of a brafs pin, which paffes through its upper and under furfaces, and through the hole already mentioned, which does not embrace the pin very tightly, in order that the toothed wheel may revolve with facility. On the upper furface of the circular cafe is an aperture directly above the line defcribed by the centres of the fluid lenfes, when moving round the central hole; and in this aperture is inferted a fmall cap, with a little hole at its top, to which the eye is applied. A moveable ftage carries the flider, on which microfcopic objects are laid, and is brought nearer or removed from the lenfes by a vertical fcrew. The objects on the flider are illuminated by a plain mirror, which has both a vertical and horizontal motion for this purpofe. When the microfcope is thus conftructed, the object to be viewed is placed upon the flider, and the endlefs fcrew is turned till one of the lenfes be directly under the aperture; and the flider is thus raifed or depreffed by the vertical fcrew, till the object be brought into the focus of the lens. In this manner, by turning the endlefs fcrew, and bringing all the lenfes, one after another, directly below the aperture, the object may be fucceffively examined with a variety of magnifying powers. Thefe fluid lenfes have been employed as the object-glaffes of compound microfcopes.

The *fingle aquatic microfcope* of Mr. Ellis has the advantage of being fimple in its conftruction, portable, and very commodious for the purpofes of practical botanifts, the obfervers of animalcula, &c. K (*fig.* 7.) reprefents the box containing the whole apparatus: it is generally made of fifhfkin; and on the top there is a female fcrew, for receiving the fcrew that is at the bottom of the pillar A: this is a pillar of brafs, and is fcrewed on the top of the box. D is a brafs pin which fits into the pillar; on the top of this pin is a hollow focket to receive the arm which carries the magnifiers; the pin is to be moved up and down, in order to adjuft the lenfes to their focal or proper diftance from the object. [N. B. In the reprefentations of this microfcope, the pin D is delineated as paffing through a focket at one fide of the pillar A; whereas it is ufual at prefent to make it pafs down a hole bored through the middle of the pillar.] E, the bar which carries the magnifying lens; it fits into the focket socket X, which is at the top of the pin or pillar D. This arm may be moved backwards and forwards in the socket X, and sideways by the pin D; so that the magnifier, which is screwed into the ring at the end E of this bar, may be easily made to traverse over any part of the object that lies on the stage or plate B. F F is a polished silver speculum, with a magnifying lens placed at the centre thereof, which is perforated for this purpose. The silver speculum screws into the arm E, as at F. G, another speculum, with its lens, which is of a different magnifying power from the former. H, the semicircle which supports the mirror I; the pin R, affixed to the semicircle H, passes through the hole which is towards the bottom of the pillar A. B, the stage, or the plane, on which the objects are to be placed; it fits into the small dove-tailed arm which is at the upper end of the pillar D A. A plane round glass, with a small piece of black silk stuck on it, is used to lie in a circular groove made in the stage B. A hollow watch glass is to be laid occasionally on the stage instead of the plane glass. L, a pair of nippers. These are fixed to the stage by the pin at bottom; the steel wire of these nippers slides backwards and forwards in the socket, and this socket is moveable upwards and downwards by means of the joint, so that the position of the object may be varied at pleasure. The object may be fixed in the nippers, stuck on the point, or affixed, by a little gum-water, &c. to the ivory cylinder N, which occasionally screws to the point of the nippers.

To use this microscope: take all the parts of the apparatus out of the box; then begin by screwing the pillar A to the cover of it; pass the pin R of the semicircle which carries the mirror through the hole that is near the bottom of the pillar A; push the stage into the dove-tail at B, slide the pin into the pillar (see the N.B. above); then pass the bar E through the socket which is at the top of the pin D, and screw one of the magnifying lenses into the ring at F. The microscope is now ready for use: and though the enumeration of the articles may lead the reader to imagine the instrument to be of a complex nature, we can safely affirm that he will find it otherwise. The instrument has this peculiar advantage, that it is difficult to put any of the pieces in a place which is appropriated to another. Let the object be now placed either on the glasses of the stage, or in the nippers L, and in such manner that it may be as nearly as possible over the centre of the stage: bring the speculum F over the part you mean to observe; then throw as much light on the speculum as you can, by means of the mirror I, and the double motion of which it is capable; the light received on the speculum is reflected by it on the object. The distance of the lens F from the object is regulated by moving the pin D up and down, until a distinct view of it is obtained. The best rule is, to place the lens beyond its focal distance from the object, and then gradually to slide it down till the object appears sharp and well defined. The adjustment of the lenses to their focus, and the distribution of the light on the object, are what require the greatest attention: on the first the distinctness of the vision depends; the pleasure arising from a clear view of the parts under observation is due to the modification of the light. No precise rule can be given for attaining accurately these points; it is from practice alone that ready habits of obtaining these necessary properties can be acquired, and with the assistance of this no difficulty will be found.

Mr. B. Martin has also contrived a microscope for similar purposes with those to which that of Mr. Ellis is adapted. A B (*fig.* 8.) represents a small arm supporting two or more magnifiers, one fixed to the upper part as at B, the other to the lower part of the arm at C; these may be used separately or combined together. The arm A B is supported by the square pillar I K, the lower end of which fits into the socket E of the foot F G; the stage D L is made to slide up and down the square pillar; H, a concave mirror for reflecting light on the object.—To use this microscope, place the object on the stage, reflect the light on it from the concave mirror, and regulate it to the focus, by moving the stage nearer to or farther from the lens at B. The ivory sliders pass through the stage; other objects may be fixed in the nippers M, N, and then brought under the eye-glasses; or they may be laid on one of the glasses which fit the stage. The apparatus to this instrument consists of three ivory sliders; a pair of nippers; a pair of forceps; a flat glass and a concave ditto, both fitted to the stage.

The two last microscopes are frequently fitted up with a toothed rack and pinion, for the more ready adjustment of the glasses to their proper focus.

Dr. Withering, in his "Botanical Arrangements," describes a portable botanic microscope. It consists of three brass plates, A, B, C, (*fig.* 9.) which are parallel to each other; the wires D and E are rivetted into the upper and lower plates, which are by this means united to each other; the middle plate or stage is moveable on the aforesaid wires by two little sockets which are fixed to it. The two upper plates each contain a magnifying lens, but of different powers; one of these confines and keeps in their places the fine point F, the forceps G, and the small knife H.—To use this instrument, unscrew the upper lens, and take out the point, the knife, and the forceps; then screw the lens on again, place the object on the stage, and then move it up or down till you have gained a distinct view of the object, as one lens is made of a shorter focus than the other; and spare lenses of a still deeper focus may be had if required. This little microscope is the most portable of any. Its principal merit is its simplicity.

Mr. B. Martin has contrived to mount several lenses in one frame, which are convenient for various purposes, and are carried in the pocket. He calls this apparatus a "Hand Megalascope," from its use in viewing the larger sort of small objects expeditiously. The case with its three frames and lenses, is represented in *fig.* 10. The lenses are commonly of 1, 1½ and 2 inches focus; they are contrived so as to turn over each other, and that into the case. The three lenses singly afford three magnifying powers; and by combining two and two, we obtain three more; *d* with *e* making one, *d* with *f* another, and *e* with *f* a third; and all three combined together make another; so that by this simple apparatus we have seven different magnifying powers. When the three lenses are combined, it is better to turn them in, and look through them by the small apertures in the sides of the case. The eye in this case is not incommoded by external light; the aberration of the superfluous rays through the glasses is precluded; and the eye coincides more exactly with the common axes of the lenses.

M. Lyonet has invented a curious and useful microscope, for the purpose of minute dissections and microscopic preparations. A B (*fig.* 11.) is the anatomical table, which is supported by a pillar N O; this is screwed on the foot C D. The table A B is prevented from turning round by means of two steady pins. In this table or board there is a hole G, which is exactly over the centre of the mirror E F, that is to reflect the light on the object; the hole G is designed to receive a flat or concave glass, on which the objects for examination are to be placed.

R X Z is an arm formed of several balls and sockets, by which means it may be moved in every possible situation; it is fixed to the board by means of the screw H. The last

arm

arm I Z has a female ſcrew, into which a magnifier may be ſcrewed as at Z. By means of the ſcrew H, a ſmall motion may be occaſionally given to the arm I Z, for adjuſting the lens with accuracy to its focal diſtance from the object.

Another chain of balls is ſometimes uſed, carrying a lens to throw light upon the object; the mirror is likewiſe ſo mounted, as to be taken from its place at K, and fitted on a clamp, by which it may be fixed to any part of the table A B.

To uſe the Diſſecting Table.—Let the operator ſit with his left ſide near a light window; the inſtrument being placed on a firm table, the ſide D H towards the ſtomach, the obſervations ſhould be made with the left eye. In diſſecting, the two elbows are to be ſupported by the table on which the inſtrument reſts, the hands reſting againſt the board A B; and in order to give it greater ſtability (as a ſmall ſhake, though imperceptible to the naked eye, is very viſible in the microſcope), the diſſecting inſtruments are to be held one in each hand, between the thumb and two fore-fingers.

Microscopes, *Theory of Compound, or Double.* Suppoſe an object-glaſs E D, (*Plate* XII. *Optics, fig.* 1.) the ſegment of a very ſmall ſphere, and the object A B placed without the focus F.

Suppoſe an eye-glaſs G H, convex on both ſides, and the ſegment of a ſphere greater (though not too great) than that of D E; and let it be ſo diſpoſed behind the object, as that if C F : C L :: C L : C K; the focus of the eye-glaſs may be in K.

Laſtly, ſuppoſe L K : L M :: L M : L I.

If, then, O be the place in which an object is ſeen diſtinct with the naked eye; the eye, in this caſe, being placed in I, will ſee the object A B diſtinctly, in an inverted ſituation, and magnified in a compound ratio of M K to L K, and L C to C O; as is proved from the laws of dioptrics; *i. e.* the image itſelf is larger than the object, and we are able to view it diſtinctly at a leſs diſtance. *E. G.* If the image be twenty times larger than the object, and by the help of the eye-glaſs we are able to view it five times nearer than we could have done with the naked eye, it will, on both theſe accounts, be magnified 5 times 20, or 100 times.

Microscopes, *Laws of Double.* 1. The more an object is magnified by the microſcope, the leſs is its *field*, *i. e.* the leſs of it is taken in at one view.

2. To the ſame eye-glaſs may be ſucceſſively applied object-glaſſes of various ſpheres, ſo as that both the entire objects, but leſs magnified, and their ſeveral parts, much more magnified, may be viewed through the ſame microſcope. In which caſe, on account of the different diſtances of the image, the tube L K, in which the lenſes are fitted, ſhould be made to draw out. For the proportion of the object-glaſs to the eye-glaſs, ſome commend the ſubduple ratio, and ſome the ſubſeſquiſextile. De Chales will have the ſemidiameter of the convexity of the object-glaſs to be $\frac{1}{3}$ of a digit, or, at moſt, $\frac{1}{2}$; in the eye-glaſs an entire digit, or even $1\frac{1}{2}$. Cherubin makes the ſemidiameter of the object-glaſs $\frac{1}{4}$, $\frac{1}{3}$, or $\frac{1}{2}$ of a digit; the ſemidiameter of the eye-glaſs $1\frac{1}{3}$, or $1\frac{1}{2}$ of a digit.

3. Since it is proved that the diſtance of the image L K from the object-glaſs D E will be greater, if another lens, concave on both ſides, be placed before its focus; it follows, that the object will be magnified the more, if ſuch a lens be here placed between the object-glaſs D E, and the eye-glaſs G H. Such a microſcope is much commended by Conradi, who uſed an object-lens, convex on both ſides, whoſe ſemidiameter was two digits, its aperture equal to a muſtard-ſeed; a lens, concave on both ſides, 12, or at moſt 16 digits; and an eye-glaſs, convex on both ſides, of ſix digits.

4. Since the image is projected to the greater diſtance, the nearer another lens, of a ſegment of a larger ſphere, is brought to the object-glaſs; a microſcope may be compoſed of three lenſes which will magnify prodigiouſly.

5. From theſe conſiderations it follows, that the object will be magnified the more, as the eye-glaſs is the ſegment of a ſmaller ſphere; but the field of viſion will be the greater, as the ſame is a ſegment of a larger ſphere. If, then, two eye-glaſſes, the one a ſegment of a larger, the other of a ſmaller ſphere, be ſo combined, as that the object appearing very near through them, *i. e.* not farther diſtant than the focus of the firſt, be yet diſtinct; the object, at the ſame time, will be exceedingly magnified, and the field of viſion much greater than if only one lens was uſed; and the object will be ſtill more magnified, and the field enlarged, if both the object and eye-glaſs be double. But in regard an object appears dim, when viewed through ſo many glaſſes, part of the rays being reflected in paſſing through each, the multiplying of lenſes is not adviſable; and the beſt, among compound microſcopes, are thoſe which conſiſt of one object-glaſs and two eye-glaſſes. Theſe eye-glaſſes are placed ſometimes cloſe together, and ſometimes an inch aſunder; by which means, although the object appears leſs magnified, yet the viſible area is much enlarged by the interpoſition of a ſecond eye-glaſs, and thus a much pleaſanter view is obtained. This additional lens is called the amplifying glaſs, and is generally about $1\frac{1}{2}$ inch in diameter, and $2\frac{1}{2}$ inches in focal length.

Dr. Hooke tells us, in the preface to his Micrography, that in moſt of his obſervations he uſed a microſcope of this kind, with a middle eye-glaſs of a conſiderable diameter, when he wanted to ſee much of the object at one view, and took it out when he would examine the ſmall parts of an object more accurately; for the fewer refractions there are, the more light and clear the object appears.

For a microſcope of three lenſes, De Chales commends an object glaſs of $\frac{1}{3}$ or $\frac{1}{4}$ of a digit; and the firſt eye-glaſs he makes 2 or $2\frac{1}{2}$ digits; the diſtance between the object-glaſs and eye-glaſs about twenty lines. Conradi had an excellent microſcope, the object-glaſs of which was half a digit, and the two eye-glaſſes (which were placed very near) four digits; but it anſwered beſt, when, in lieu of the object-glaſs, he uſed two glaſſes, convex on both ſides, their ſphere about a digit and a half, or at moſt two, and their convexities touching each other within the ſpace of half a line. Euſtachius de Divinis, inſtead of an object-glaſs convex on both ſides, uſed two plano-convex lenſes, whoſe convexities touched; Grindelius did the ſame, only that the convexities did not quite touch. Zahnius made a binocular microſcope, in which both eyes were uſed.

It is obſerved that compound microſcopes ſometimes exhibit a fallacious appearance, by repreſenting convex objects concave, and *vice verſâ*. See Phil. Tranſ. N° 476. p. 387.

The magnifying power of a microſcope with more than two lenſes, muſt be computed from the effect of all the lenſes (ſee Lens); or it may be aſcertained experimentally in the following manner. Place part of a divided ruler before the microſcope, ſo that, looking through the inſtrument, you may ſee one of its diviſions magnified; then open the other eye alſo, and looking with it at the ruler out of the microſcope, you will perceive the image of the magnified diviſion as it were projected upon the ruler; and you may eaſily ſee how many diviſions of the unmagnified ruler meaſure, or are equal to, the ſingle magnified diviſion, and that numbe is the magnifying power of that microſcope. Thus, if the ruler

ruler be divided after the common way into inches and tenths, and if you find that one magnified tenth is equal to three inches, you may conclude that the microscope magnifies 30 times.

MICROSCOPE, *Structure or Mechanism of a Double.* The industry and address of our countryman, Mr. Marshal, here deserve to be remembered: the construction of the original double microscope being of his contrivance. In this the eye-glass is at W (*Plate* XIII. *fig.* 1.) the object-glass at C, the middle glass at A 1: B is the cover or lid, to keep out the dust from the eye-glass W; X is the place of the eye, W a screw where the eye-glass lies; A 1 a screw where the middle glass lies; A 2 the drawer, where the outermost tube A 1 A 2 is disjoined from the inner one, of the same length; Z the frame or basis on which the microscope stands firm; T a small drawer in the frame or basis, with a ledge or till in it, having six partitions to hold so many several object-glasses, one magnifying more than another, and fixed in brass cells ready to screw on at C, and marked 1, 2, 3, 4, 5, 6; these partitions are also marked 1, 2, 3, 4, 5, 6; the other part of the drawer serves to hold the object-plate; a pair of small nippers, to take up, or handle any object conveniently; another object-plate, having one side white and the other black, to fix your objects upon, as black upon white, and white objects on black. L M is a brass ball and socket, on which the whole body of the microscope is moveable, so as to lie in any position for the light. L K, a square brass pillar, on which the microscope is moveable up and down, by means of the collar E, into which the arm D (holding the microscope) is continued. G, another brass collar sliding up and down on the pillar L K, having a small screw H, by which it is, as occasion serves, fixed fast to the said pillar, at any height. I, a large brass nut, in whose centre is a female screw, fitted to the male screw F, which is fixed in the collar E; by the turning of which nut I (the collar G being first fixed to the pillar by the screw H) the microscope is raised up or down on the pillar, and made to come nearer or go farther from the object P *c*; and, which is also a very great advantage, the axis of the microscope is always kept perpendicular to that point of the object, over which it was first placed; so that here is not the inconvenience which occurs in other glasses of often losing the sight of the object, by screwing the glass C higher or lower. P Q is a glass object-plate fixed in a brass frame, whose arm N N is fixed to the pillar by means of the nut O. The arm N N hath in it a slit, by which it is easily put on, or taken off the pillar, and by which it may be fixed upon it at any distance. P, a small fish lying on the glass-plate, that the circulation of the blood may be seen in the end of the tail-fin. R, a convex glass, by whose help a bright spot of light is brought from a candle at S, standing on the ground, while the microscope stands on the edge of a table or stool, which spot of light, *c*, serves to render the circulation more conspicuous. V, a leaden coffin to be put on the fish, to hinder it from springing away, and moving his tail out of the light. 1, 2, 3, 4, 5, 6, are marked on the pillar L K, to shew the respective distances of the object-glasses from the object you look upon according as the object-glasses you make use of magnify more or less. Thus, for instance, if you use the object-glass 5 or 6 (either of which will shew the circulation of the blood) you must fix the upper edge of the collar E, at the mark 5 or 6 on the pillar. And then the microscope will be very near its exact distance from the object; so that by a small turn or two of the nut I one way or the other, to be found by trial, you may soon fit it exactly to your own eye.

By this microscope liquors also may be very commodiously examined; for if you place a small drop of any liquor on the glass-plate, just in the middle of the spot of light *c*, the parts of it will become very visible, and its animalcula, if it have any, will be discovered. And thus may the eels in vinegar, the small creatures in black-pepper water, or in water where wheat, barley, &c. has been infused, the eels and other small living creatures in puddle-water, be as plainly seen as by almost any other microscope.

In the microscope, in which the objects are illuminated by reflection, made by Mr. Culpeper and Mr. Scarlet, as an improvement of Mr. Marshal's, the inner tube, *a b*, (*fig.* 2) which slides in the outer, *c d*, holds all the glasses. The eye-glass is at *a a*, the broad middle glass at *b b*, and the object-glass, being set in a button at *e*, is screwed upon the end of a narrower tube *f g*; which being fixed in the base of the inner tube, passes freely through a hole in the base of the outer. The buttons that contain several object-glasses are marked 1, 2, 3, &c. and the convexity of the inner tube is also marked with dotted circles, numbered 1, 2, 3, &c. in order to bring that circle to coincide with the mouth *c c* of the outer tube, whose number is the same as that of the object-glass then made use of. But if the object does not yet appear quite distinct, the pinion R must be turned, which, by a rack on the tube of the microscope, brings it nearer to the object placed below it. Of these glasses the greater magnifiers are known by their having smaller apertures.

The base *d d* of the outer tube is supported by three brass pillars, fixed into a wooden pedestal *h*; and a little below the object-glass *f*, a circular plate *i k* is fixed like a stage between the pillars, having a circular hole in the centre to receive glasses, &c. to place objects upon. Three small brass circles *m n*, with holes through the middle of them, are to be placed over the hole in the middle of the stage; and then the ivory sliders with objects may be put between the two uppermost of these circles, which are pressed together by a spiral springing wire lodged between the two undermost; the two outermost being held together by two small pillars passing through two holes in the circumference of the middle circle. For viewing the circulation of the blood, the button *p*, on the under side of the frame of a broad plane glass *q r*, being put through a slit made in the stage, a small brass bolt *s*, under the stage, must be shoved inwards, till a smaller slit in it embraces the neck of the said button; and then the fish being laid upon this glass, and covered with the leaden coffin V, (*fig.* 1.) its tail may be brought exactly under the object-glass by turning the glass *p q* about the button, or by shoving it inwards or outwards along the slit in the stage. The circular object-plate *v x* has a like button in its centre, to be put into the same slit as before; and then the different objects, placed between two talcs in the holes made round the circumference of the plate, may be viewed successively by turning the plate about its centre.

All these transparent objects are illuminated extremely well in this microscope, either by candle-light or sky-light reflected upwards from a concave looking-glass *y z*, placed in a frame from the centre *h* of the pedestal. While you are viewing the object through the microscope, turn this concave upon its horizontal poles *y*, *z*, and you will soon find out that position of it in which it reflects the most light through the hole in the stage upon the object; and this happens when it reflects the rays very obliquely. Opaque objects, when laid upon a black ebony or a white ivory plate, put into the hole upon the stage, may be illuminated by candle-light transmitted through a double convex lens $\alpha\beta$; the stem of the frame $\alpha\beta$, in which it turns, being put into the hole in the stage. The candle must be placed in a line drawn from the object through the middle of this lens, at such a distance from it as

 shall

ſhall cauſe the ſpot of light upon the object-plate to be the narroweſt. By day-light this lens gives little or no advantage to the direct ſky-light.

Mr. Adams, in his "Eſſays," has deſcribed an improvement of this kind of microſcope, which is as follows: A B (*Plate* XIV. *fig.* 1.) repreſents the body of the microſcope, containing a double eye-glaſs and a body-glaſs: it is here ſhewn as ſcrewed to the arm C D, from whence it may be occaſionally removed, either for the convenience of packing, or when the inſtrument is to be uſed as a ſingle microſcope.

The eye-glaſſes and the body-glaſſes are contained in a tube which fits into the exterior tube A B; by pulling out a little this tube when the microſcope is in uſe, the magnifying power of each lens is increaſed.

The body A B of the microſcope is ſupported by the arm C D; this arm is fixed to the main pillar C F, which is ſcrewed firmly to the mahogany pedeſtal G H; there is ſometimes a drawer to this pedeſtal, which holds the apparatus.

N I S, the plate or ſtage which carries the ſlider-holder K L: this ſtage is moved up or down the pillar C F, by turning the milled nut M; this nut is fixed to a pinion, that works in a toothed rack cut on one ſide of the pillar. By means of this pinion, the ſtage may be gradually raiſed or depreſſed, and the object adjuſted to the focus of the different lenſes.

K L is a ſlider-holder, which fits into a hole that is in the middle ſtage N I S; it is uſed to confine and guide either the motion of the ſliders which contain the objects, or the glaſs tubes that are deſigned to confine ſmall fiſhes for viewing the circulation of the blood. The ſliders are to be paſſed between the two upper plates, the tubes through the bent plates.

L is a braſs tube, to the lower part of which is fixed the condenſing lens for concentrating the light reflected up from the mirror O; it fits into the under part of the ſlider-holder K L, and may be ſet at different diſtances from the object, according to its diſtance from the mirror or the candle.

O is the frame which holds the two reflecting mirrors, one of which is plane, the other concave. Theſe mirrors may be moved in various directions, in order to reflect the light properly, by means of the pivots on which they move, in the ſemicircle Q S R, and the motion of the ſemicircle itſelf on the pin S: the concave mirror generally anſwers beſt in the day-time; the plane mirror combines better with the condenſing lens, and a lamp or candle. At D there is a ſocket for receiving the pin of the arm Q (*fig.* 2.) to which the concave ſpeculum R, for reflecting light on opaque objects, is ſcrewed. At S is a hole and ſlit for receiving either the nippers *a b c* (*fig.* 7.), or the fiſh-pan (*fig.* 8.); when theſe are uſed, the ſlider-holder muſt be removed. A hole is made in the oppoſite ſide of the ſtage to receive the pin *g* of the convex lens S, *fig.* 3.

To uſe this microſcope: Take it out of the box. Screw the body into the round end of the upper part of the arm C D. Place the braſs ſliders, which contain the magnifiers, into the dove-tailed ſlit which is on the under ſide of the aforeſaid arm, as ſeen at E, and ſlide it forwards until the magnifier you mean to uſe is under the centre of the body: oppoſite to each magnifier in this ſlit there is a notch, and in the dove-tailed part of the arm C D there is a ſpring, which falls into the above-mentioned notch, and thus makes each magnifier coincide with the centre of the body. Paſs the ivory ſlider you intend to uſe between the upper plates of the ſlider-holder K L, and then reflect as ſtrong a light as you can on the object by means of one of the mirrors; after this, adjuſt the object to the focus of the magnifier and your eye, by turning the milled ſcrew M, the motion of which raiſes and depreſſes the ſtage N I S. The degree of light neceſſary for each object, and the accuracy required in the adjuſtment of the lenſes to their proper focal diſtance from the object, will be eaſily attained by a little practice.

When *opaque* objects are to be examined, remove the ſlider-holder, and place the object on a flat glaſs, or fix it in the nippers (*fig.* 7.); the pin *c* of theſe fits into the hole on the ſtage; ſcrew the concave ſpeculum R into the arm Q (*fig* 2.) and then paſs the pin of this arm through the ſocket D, (*fig.* 1.) the light is now to be reflected from the concave mirror to the ſilver ſpeculum, and from this down on the object. No exact rule can be given for reflecting the light on the object; we muſt therefore refer the reader to the mother of all aptneſs, practice. The ſpeculum muſt be moved lower or higher, to ſuit the focus of the different magnifiers and the nature of the object.

The foregoing directions apply equally to the uſing of this inſtrument as a *ſingle* microſcope; with this difference only, that the body A B is then removed, and the eye is applied to the upper ſurface of the arm C D, exactly over the magnifiers.

This microſcope is ſometimes made with the following *alterations*, which are ſuppoſed to render it ſtill more convenient and uſeful. The arm C D that carries the body and magnifiers is made both to turn on a pin, and to ſlide backwards and forwards in a ſocket at C; ſo that, inſtead of moving the objects below on the ſtage, and diſturbing them, the magnifiers are more conveniently brought over any part of the objects as deſired. The condenſing glaſs is made larger, and ſlides upon the ſquare bar C F quite diſtinct from the ſtage, like the mirrors below; and it is thereby made uſeful for any other objects that may be applied on glaſſes fitted to the ſtage, as well as thoſe put into the ſlider-holder K. It is thereby not confined to this ſtage alone, as in the preceding. When the body A B is taken away, the arm C D may be ſlipt away from its bar, with the magnifiers, and the forceps, wire, and joint, applied to it as at *fig.* 7.; and it thereby ſerves the purpoſe of a ſmall hand ſingle or opaque microſcope, for any object occaſionally applied to this wire. The magnifiers in the ſlider E are mounted in a wheel caſe, which perhaps prevents its being in the way ſo much as the long ſlider E before deſcribed. This contrivance is repreſented in *fig.* 5, and ſeparated in *fig.* 4.

Mr. Martin's new univerſal compound microſcope, which combines the uſes and advantages of the ſingle, compound, opaque, and aquatic microſcopes, as now conſtructed by the opticians of London, is repreſented in *fig.* 5. A, B, D, is the body of the microſcope; which conſiſts of four parts, *viz.* A B the eye-piece, or that containing the eye-glaſſes, and is ſcrewed into the top of a moveable or ſliding tube which contains the body-glaſs ſcrewed into its lower part. D is the exterior tube or caſe, in which the other ſlides up and down in an eaſy and ſteady manner. This motion of the interior tube is uſeful to increaſe or decreaſe the magnifying power of the body-glaſs when thought neceſſary, as before-mentioned. E is a pipe or ſnout ſcrewed on to the body of the microſcope D, and at its lower part, over the ſeveral magnifying lenſes hereafter deſcribed. F G H I is the ſquare ſtem of the microſcope, upon which the ſtage R moves in an horizontal poſition, upward or downward, by means of the fine rack-work of teeth and pinion. K L is a ſtrong ſolid joint and pillar, by which the poſition of the inſtrument is readily altered from a vertical one to an oblique or to a perfectly horizontal one, as may be required: it is thus well adapted to the eaſe of the obſerver either ſitting or ſtanding; and as it is very often convenient to view objects by direct unreflected light, when the ſquare ſtem F I is placed in an horizontal poſition for this purpoſe, the mirror T is then to be taken off in order to prevent the obſtruction of the

the rays. N O P, the tripod or foot by which the whole body of the microſcope is ſteadily ſupported; theſe three arms fold up under each other at N, when packed into the caſe. W is a braſs frame, that contains the condenſing lens, and acts in conjunction with the large concave and plane mirrors below at T; the reflected rays from which, either of the common light or of that of a candle or lamp, it agreeably modifies, and makes ſteady in the field of view.

The particulars of the apparatus to this microſcope are as follow: Q (ſee alſo *fig.* 4.) is a circular braſs box, containing ſix magnifiers or object lenſes, numbered 1, 2, 3, 4, 5, 6; the digits of which appear ſeverally through a ſmall round hole *y*, (*fig.* 4.) in the upper plate of it. To the upper ſide is fixed a ſmall circle of braſs *z*, by which it is connected with, and ſcrewed into, the round end of the arm *a b c d*; which is a long piece of braſs, and moves through either by teeth or pinion, or not, as may be deſired, in *e f*; which is a ſocket on the upper part of the pillar, and admits, with a motion both eaſy and ſteady, the braſs arm. R is a fixed ſtage, upon which the objects to be viewed are to be placed: it is firmly faſtened to the ſquare pillar, which is moved by the rack-work. In the middle is a large circular hole, for receiving concave glaſſes, with fluids, &c. it has alſo a ſliding ſpring-frame to faſten down ſlips of glaſs or other things: at *q t x* are three ſmall ſockets or holes, intended to receive ſeveral parts of the apparatus. S is the refractor, or illuminating lens, for converging the ſun's rays upon opaque objects laid upon the ſtage R. Or it may be fixed, as in *fig.* 3. to move in a ſemicircle, fixing its long ſhank *g*, in a ſpring ſocket *h*, in the arm *i*; this arm moving every way by a ſtout pin *k* in the ſocket *t* of the ſtage. In this manner it is eaſily adjuſted to any poſition of the ſun, candle, &c.—T, the reflecting-glaſs frame, containing a concave and plane ſpeculum, which is moved upon the ſquare pillar by the hand. The uſe of it is to illuminate all tranſparent objects that are applied to the ſtage above.

Beſides the apparatus repreſented, there is an auxiliary moveable ſtage; which by means of a pin is placed in the hole *t* of the ſtage R, and can be moved in an horizontal direction over the whole field of the ſtage. In this ſtage, there are three circular holes with ſhouldered bottoms; a large one in the middle, and on each ſide a ſmall one, for the reception of the three following neceſſary articles: a watch-glaſs to be placed in the large hole, to hold fluids containing animalcules, &c.; a circular piece of ivory, one ſide of which is black, the other white, to ſupport opaque objects of different contraſted colours; and circular plane and concave glaſſes, for extemporaneous tranſparent objects.—The ſame uſe is made of the two ſmall holes as of the large one, only in a leſſer degree, to receive ſmall concave glaſſes, plates, &c.

L (*fig.* 6.) is the ſilvered ſpeculum, called a *Lieberkhun*, which makes the ſingle opaque microſcope, by being ſcrewed to the ſlider *a b c* (*fig.* 5.) in room of the box of lenſes Q, and the body A E above it. The chief uſe of this is to view very ſmall objects ſtrongly illuminated near the compounded focus of the mirror T (*fig.* 5.) In *fig.* 7. are the forceps or pliers, for holding ſuch kind of objects, and by which they can be applied very readily to the focus of the lens in the Lieberkhun. They have a motion all ways by means of the ſpring ſocket *a*, the joint *b*, and the ſhank *c*: they are placed with the pin *c* in the ſocket *t* of the fixed ſtage R (*fig.* 5.) and 7 is a ſmall piece of ivory, to be placed upon the pointed end of the pliers: it is black upon one ſide, and white upon the other, to receive opaque objects.

R (*fig.* 2.) is a Lieberkhun of a larger ſize than that firſt mentioned, with a hole in its centre: this is ſcrewed into the hole Q of a braſs ring, faſtened to a long wire *d*; which moves up and down in the ſpring ſocket *x* of the ſtage R, (*fig.* 5.) in which it alſo moves ſideways; and thus, with the body A E above, forms an *aquatic compound* microſcope for ſhewing all ſorts of objects in water and other fluids placed under it in a watch-glaſs on the ſtage.

Sometimes a cone is uſed, with a proper aperture to exclude ſuperfluous light, that would diſturb a critical obſervation of a curious object; it is ſcrewed to the under ſide of the fixed ſtage R.

There is what is uſually called a bug-box, conſiſting of a concave glaſs with a plane one ſcrewed over it; by means of which a bug, louſe, flea, &c. may be ſecured and viewed alive. It is to be placed on the ſtage. R

Fig. 8. is the fiſh-pan. In the long concave body *a b*, a fiſh may be ſo confined by the ribband *c*, that the tranſparent tail may be in part over the ſlit or hole at *d*. In this ſtate, it is placed on the ſtage R, with the pin *d* in the hole *t* of the ſtage, and moves freely and horizontally for viewing the circulation of the blood, &c.

A ſlider-holder may be placed on the ſtage R: it receives the ſliders and tubes when filled with tranſparent objects, to be viewed either by the compound or ſingle microſcope.

Fig. 9. repreſents the ivory ſlider, to hold the objects between the tales as uſual.

Fig. 10. is a uſeful auxiliary ſlider framed in braſs. In this ſlider ſmall concave glaſſes are cemented; and a ſlip of plane glaſs ſlides over them; by which any ſmall living object, as mites, &c. may be confined without injury, and deliberately viewed.

The inſtrument has a ſet of glaſs tubes, three in number, one within another; they are uſeful for ſmall tadpoles, waternewts, eels, &c. when the circulation of the blood is to be viewed. There is a ſmall hole at one end of each tube, that ſerves to admit the air; for when they are filled with water, the other end is ſtopped with a cork.

A ſmall ivory box, containing ſpare tales and wires, to ſupply the ſliders with occaſionally.

X, (*fig.* 6.) is a braſs cell or button, containing a very ſmall lens, properly ſet between two ſmall plates of braſs, that it may be brought very near to the object when viewed with it as a ſingle microſcope. This magnifier is ſcrewed into the ſame hole as the wheel of ſix magnifiers Q are in *fig.* 5.

There is a lens, adapted to view and examine objects, by magnifying them ſufficiently, ſo as to be able to apply them to the microſcope for inſpection: on this account it is called the *explorator*.

The preceding are the chief articles of the apparatus; which, on account of their being ſomewhat different from what is applied to other microſcopes, we have been thus particular in deſcribing. In uſing the microſcope, and while viewing objects by either the ſingle or compound inſtrument, the focal diſtances of the magnifiers are made perfectly exact by turning of the pinion at the nut *w*, in one way or the other, very gently in the teeth of the rack-work at the front of the bar F I.

It is neceſſary that the centres of the object lenſes or magnifiers, the ſtage, and the mirrors at bottom, ſhould all be in a right line in the axis of the microſcope, when opaque objects are to be viewed, that are placed upon the ivory plate 7, or the forceps, and all other ſuch ſorts of objects which are placed in the centre of the ſtage R, or the ſlider-holder: but when aquatic or living objects, which require a great ſpace to move in, are to be viewed, then the horizontal motion at *e f* (*fig.* 5.) is made uſe of, and the view may be extended laterally over the whole of the diameter of the object or field of view; and by putting the arm *a b c* forward or or backward in its socket *e f*, the view is extended in the contrary direction equally well; and in this manner the whole of the objects may be viewed without the least disturbance.

As the brass arm *a b c* may be brought to the height of three or four inches above the stage R; so, by means of the rack-work motion of the stage, a lens of a greater focal distance than the greatest in the wheel Q may be occasionally applied in place of the wheel, and thereby the larger kind of objects be viewed; the instrument becoming, in this case, what is called a *megalascope*. Two sizes of these lenses, furnished with Lieberkhuns, are shewn at L M, *fig.* 6.

In viewing moving living objects, or even fixed ones, when nice motions are requisite, a rack-work and pinion is often applied to the arm *a b c*: the arm is cut out with teeth; and the pinion, as shewn at Y, is applied to work it. This acts but in one direction; and, in order to produce an equally necessary motion perpendicular to this, rack-work and pinion is applied tangent-wise to the stage, which is then jointed.

To fit microscopes, as well as telescopes, to short-sighted eyes, the object-glass and the eye-glass must be placed a little nearer together, so that the rays of each pencil may not emerge parallel, but may fall diverging upon the eye.

MICROSCOPE, *Reflecting*, is properly that which magnifies by reflection, as the above-mentioned ones do by refraction.

The structure of such a microscope may be conceived thus: near the focus of a concave speculum, AB (*Plate* XIII. *fig.* 3.) place a minute object C, that its image may be formed larger than itself in D; to the speculum join a lens, convex on both sides, E F, so as the image D may be in its focus.

The eye will here see the image inverted, but distinct, and enlarged; consequently, the object will be larger than if viewed through the lens alone.

The inventor of this microscope is the great sir I. Newton; but the objects appear dim in it.

Any telescope is converted into a microscope, by removing the object-glass to a greater distance from the eye-glass. And since the distance of the image is various, according to the distance of the object from the focus; and it is magnified the more, as its distance from the object-glass is greater; the same telescope may be successively converted into microscopes, which magnify the object in different degrees.

The construction of this microscope is more particularly explained in *fig.* 4. in which, instead of the lens d e f, there is placed a small speculum *d e f*; so that the object *a c b* being placed above it, at a little greater distance from the focus *g*, has its image A C B, formed by reflection, as in the other case it was by refraction, through the lens d f. Now if we suppose the focal distance of the object speculum *d e f*, and lens d e f the same, the effect of the microscope in other respects will be the same also.

For the distance of the object *a b* above the speculum, will be equal to the distance of the object a b below the lens, in order that the image may be formed at the same distance C *e*. The position of the object will be inverted; for all the rays flowing from the point *a*, will be reflected by the speculum to the point A, in the same manner as if they came by refraction through the lens from the point a. Thus the part *b* in the object will be reflected to the focus B in the image, which, therefore, is inverted. The power of magnifying will also be the same in this and in the reflecting telescope of a similar construction. For since the image A B and the object *a b* are seen under equal angles from the vertex *e* of the speculum, the triangles *a e b*, and A *e* B will be similar, and therefore A B : *a b* :: C *e* : *c e*; but in the other it is A B : a b :: C e : c e. But the latter ratio of these analogies is the same in both, and consequently the first is so too. This microscope is not so easy to manage as the common sort. For vision by reflection, as it is much more perfect, so it is far more difficult than that by refraction. Nor is this microscope so useful for any but very small or transparent objects. For the object, being between the speculum and image, would, if it were large and opaque, prevent a due reflection.

In Dr. Smith's reflecting microscope there are two reflecting mirrors, one concave and the other convex, and the image is viewed by a lens. To explain it, let A D (*fig.* 5.) be a large concave speculum, and *a d* a small convex one, each perforated in the middle with the holes B C, *b c*. Both these are segments of the same sphere, or ground on tools of an equal radius, *viz.* of two inches, that so the focal distance of each speculum may be just one inch.

These two speculums are placed at the distance of about 1½ inch from each other, that so an object O P Q, being placed a little below the smaller speculum, might be between the focus F and centre E of the larger speculum. Things thus circumstanced, the rays P A, P D, which flow from the point P in the object, on the speculum A D, will be reflected towards a focus *p*, where an image *o p q* would be formed, if the rays were not intercepted by the convex speculum *a d*; and the point *p* being nearer than its focus *f*, the rays A *a*, D *d*, which tend or converge towards it, will be reflected to a focus *P*, where the last image, *O P Q*, will be formed, to be viewed through the eye-glass G, by the eye at I.

This microscope, though far from being executed in the best manner, performed, Dr. Smith says, nearly as well as the very best refracting microscopes; so that he did not doubt, but that it would have excelled them, if it had been executed properly. Dr. Smith's own account of this instrument may be seen in his Optics, Remarks, p. 94.

MICROSCOPE, *Solar*, called also the *camera obscura* microscope, was invented by Mr. Lieberkuhn in 1738 or 1739, and is composed of a tube, a looking-glass, a convex lens, and a Wilson's microscope. The tube *c* (*fig.* 6.) is brass near two inches in diameter, fixed in a circular collar of mahogany, with a groove on its periphery on the outside, denoted by 2, 3, and connected by a cat-gut to the pulley 4 on the upper part; which turning round at pleasure, by the pin 5 within, in a square frame, may be adjusted easily to a hole in the shutter of a window, by the screws 1, 1, in such a manner that no light can pass into the room, but through the aforesaid tube *c*. Fastened to the frame by hinges, on the side that goes without the window, is a looking-glass G, which, by means of a jointed brass-wire, 6, 7, and the screw H 8, coming through the frame, may be moved either vertically or horizontally, to throw the sun's rays through the brass tube into the darkened room. The end of the brass tube without the shutter has a convex lens, 5, to collect the rays, thrown on it by the glass G, and bring them to a focus in the other part, where D is a tube sliding in and out, to adjust the object to a due distance from the focus; and to the end G of another tube F, is screwed one of Wilson's simple pocket microscopes, containing the object to be magnified in a slider; and by the tube F, sliding on the small end E of the other tube D, it is brought to a true focal distance.

The solar microscope has been introduced into the small and portable, as well as the large camera obscura; and if the image be received upon a piece of half-ground glass, shaded from the light of the sun, it will be sufficiently visible. M. Lieberkuhn made considerable improvements in his solar microscope, particularly in adapting it to the view of opaque objects; and M. Æpinus, Nov. Com. Petrop. vol. ix. p. 326, has contrived, by throwing the light upon the foreside of any object, before it is transmitted through the

the object lens, to represent with equal advantage all kinds of objects by it. In this improvement, the body of the common solar microscope is retained, and only an addition made of two brass plates, C A and B A (*fig.* 7.) joined by a hinge, and kept at a proper distance by a screw. A section of these plates, and of all the necessary parts of the instrument, may be seen in *fig.* 8, where *c*, *a*, represent rays of the sun converging from the illuminating lens, and falling upon the mirror *d b*, which is fixed to the nearer of the brass plates. From this they are thrown upon the object at *e f*, and thence are transmitted through the object lens at K, and a perforation in the farther plate, upon a screen, as usual. The use of the screw *n* is to vary the distance of the two plates, and thereby to adjust the mirror to the object with the greatest exactness. A very considerable improvement may be made in the solar microscope, by substituting Ramsden's achromatic eye-piece instead of the convex object-lens. For M. Euler's method of introducing vision by reflected light into this microscope, see MAGIC *lantern*.

An improved *solar* microscope, as used with the improved single microscope, with teeth and pinions, is exhibited in *Plate* XV. *figs.* 1, 2, and 3. The former figure represents the whole form of the single microscope; the parts of which are as follows: A B C D the external tube; G H I K the internal moveable one; Q M part of another tube within the last, at one end of which is fixed a plate of brass hollowed in the middle, for receiving the glass tubes: there is also a moveable flat plate, between which, and the fixed end of the second tube, the ivory sliders are to be placed. L, a part of the microscope, containing a wire spiral spring, keeping the tube Q M with its plates firm against the fixed part I K of the second tube.

E F is the small rack-work of teeth and pinion, by which the tube I G is moved gradually to or from the end A B, for adjusting the objects exactly to the focus of different lengths. N O is a brass slider, with six magnifiers; any one of which may easily be placed before the object. It is known when either of the glasses is in the centre of the eye-hole, by a small spring falling into a notch in the side of the slider, made against each of the glasses. Those parts of the apparatus before described, *viz.* iron-sliders, with holder, glass tubes, forceps, Lieberkhuns, buttons, &c. &c. are made use of to this microscope. G H is a brass cell, which holds an illuminating glass for converging the sun's beams, or the light of a candle strongly upon the objects. The aperture of the glass is made greater or less, by two circular pieces of brass, with holes of different sizes, that are screwed separately over the said lens. But at times, objects appear best, when the microscope is held up to the common light only, without this glass. It is also taken away when the microscope is applied to the apparatus now to be described.

Fig. 2. represents the apparatus, with the single microscope screwed to it, which constitutes the *solar* microscope. A B is the inner moveable tube, to which the single microscope is screwed. C D is the external tube, containing a condensing convex glass at the end D, and is screwed into the plate E F, which is cut with teeth at its circumference, and moved by the pinion I, that is fixed with the plate G H. This plate is screwed fast against the window-shutter, or board fitted to a convenient window of a darkened room, when the instrument is used. K L is a long frame, fixed to the circular plate E F; containing a looking-glass or mirror for reflecting the solar rays through the lens in the body of the tube D. O is a brass milled head, fastened to a worm or endless screw; which on the outside turns a small wheel, by which the reflecting mirror M is moved upwards or downwards.

In using this microscope, the square frame G H is first to be screwed to the window-shutter, and the room well darkened: which is best done by cutting a round hole of the size of the moveable plate E F, that carries the reflector, in the window-shutter or board; and by means of two brass nuts *a*, *a*, let into the shutter to receive the screws P, P, when placed through the holes in the square frame G H, at the two holes Q, Q; which will firmly fasten the microscope to the shutter, and is easily taken away by only unscrewing the screws P, P.

A white paper screen, or white cloth to receive the images, is to be placed several feet distant from the window: which will make the representations the larger in proportion to the distance. The usual distances are from six to 16 feet.

The frame K L, with its mirror M, is to be moved by turning the pinion I, one way or the other, till the beams of the sun's light come through the hole into the room: then, by turning of the worm at O, the mirror must be raised or depressed, till the rays become perfectly horizontal, and go straight across the room to the screen. The tube C D, with its lens at D, is now to be screwed into the hole of the circular plate E F: by this glass the rays will be converged to a focus; and from thence proceed diverging to the screen, and there make a large circle of light. The single microscope, (*fig.* 1.) is to be screwed on to the end A B (*fig.* 2.) of the inner tube; and the slider N O, with either of the lenses marked 1, 2, 3, 4, 5, or 6, in the centre of the hole at the end A B. This will occasion a circle of light upon the screen much larger than before. The slider or glass tube, with the objects to be viewed, is to be placed between the plates at I K against the small magnifier, and moved at pleasure. By shifting the tube A B in or out, you may place the object in such a part of the condensed rays as shall be sufficient to illuminate it, and not scorch or burn it; which will generally require the glass to be about one inch distant from the focus. It now remains only to adjust the object, or to bring it so near to the magnifier that its image formed upon the screen shall be the most distinct or perfect: and it is effected by gently turning the pinion F, (*fig.* 1.) a small matter one way or the other. If the object be rather large in size, the least magnifiers are generally used, and *vice versâ*.

N° 1. is the greatest magnifier, and N° 6. the least, in the brass slider N O. But, if desired, single lenses of greater magnifying powers are made: and they are applied, by being screwed to the end A B, (*fig.* 1.) and the brass slider N O is then taken away.

The same object may be variously magnified, by the lenses severally applied to it; and the degree of magnifying power is easily known by this rule: *As the distance of the object is to that of its image from the magnifier; so is the length or breadth of the object to that of the image.*

Instead of the brass sliders with the lenses N, O, there is sometimes screwed a lens of a large size, and longer focal distance: the instrument is then converted into a *megalascope*; and is adapted for viewing the larger kind of objects contained in larger sliders, such as is represented at R (*fig.* 3.) And, in the same manner, small objects of entertainment, painted upon glass like the sliders of a magic lanthorn, are much magnified, and represented upon the same screen.

The *lucernal* microscope of Mr. Adams, as mounted to view opaque objects, is represented in *fig.* 4. A B C D is a large mahogany pyramidal box, which forms the body of the microscope; it is supported firmly on the brass pillar F G, F G, by means of the ſocket H and the curved piece I K.

L M N is a guide for the eye, in order to direct it in the axis of the lenſes; it conſiſts of two braſs tubes, one ſliding within the other, and a vertical flat piece, at the top of which is the hole for the eye. The outer tube is ſeen at M N, the vertical piece is repreſented at L M. The inner tube may be pulled out or puſhed in, to adjuſt it to the focus of the glaſſes. The vertical piece may be raiſed or depreſſed, that the hole, through which the object is to be viewed, may coincide with the centre of the field of view; it is fixed by a milled ſcrew at M, which could not be ſhewn in this figure.

At N is a dove-tailed piece of braſs, made to receive the dove-tail at the end of the tubes M, N, by which it is affixed to the wooden box A B C D E. The tubes M, N, may be removed from this box occaſionally, for the convenience of packing it up in a leſs compaſs.

O P, a ſmall tube which carries the magnifiers.

O, one of the magnifiers; it is ſcrewed into the end of a tube, which ſlides within the tube P; the tube P may be unſcrewed occaſionally from the wooden body.

Q R S T V X, a long ſquare bar, which paſſes through the ſockets Y, Z, and carries the ſtage or frame that holds the objects; this bar may be moved backward or forward, in order to adjuſt it to the focus by means of the pinion which is at *a*.

b, a handle furniſhed with an univerſal joint, for more conveniently turning the pinion. When the handle is removed, the nut (*fig.* 5.) may be uſed in its ſtead.

d e, a braſs bar, to ſupport the curved piece K I, and keep the body A B firm and ſteady.

f g h i, the ſtage for opaque objects: it fits upon the bar Q R S T by means of the ſocket *h i*, and is brought nearer to or removed farther from the magnifying lens by turning the pinion *a*: the objects are placed in the front ſide of the ſtage (which cannot be ſeen in this figure) between four ſmall braſs plates: the edges of two of theſe are ſeen at *k l*. The two upper pieces of braſs are moveable; they are fixed to a plate, which is acted on by a ſpiral ſpring, that preſſes them down, and confines the ſlider with the objects: this plate, and the two upper pieces of braſs, are lifted up by the ſmall nut *m*.

At the lower part of the ſtage, there is a ſemicircular lump of glaſs *n*, which is deſigned to receive the light from the lamp (*fig.* 29.), and to collect and throw it on the concave mirror *o*, whence it is to be reflected on the object.

The upper part *f g r s* (*fig.* 4.) of the opaque ſtage takes out, that the ſtage for tranſparent objects may be inſerted in its place.

Fig. 6. repreſents the ſtage for tranſparent objects; the two legs 5 and 6 fit into the top of the under part *r s h i* of the ſtage for opaque objects; 7 is the part which confines or holds the ſliders, and through which they are to be moved; 9 and 10 a braſs tube, which contains the lenſes for condenſing the light, and throwing it upon the object: there is a ſecond tube within that, marked 9 and 10, which may be placed at different diſtances from the object by the pin 11.

When this ſtage is uſed as a ſingle microſcope, without any reference to the lucernal, the magnifiers, or object lenſes, are to be ſcrewed into the hole 12, and to be adjuſted to a proper focus by the nut 13.

N. B. At the end A B (*fig.* 4.) of the wooden body there is a ſlider, which is repreſented as partly drawn out at A; when quite taken out, three grooves will be perceived; one of which contains a board that forms the end of the box; the next contains a frame with a greyed glaſs; and the third, or that fartheſt from the end A B, two large convex lenſes.

In the uſe of this microſcope for examining opaque objects, take out the wooden ſlider A (*fig.* 4.), then lift out the cover and the grey glaſs from their reſpective grooves under the ſlider A.

Put the end N of the guide for the eye L M N into its place, ſo that it may ſtand in the poſition which is repreſented in this figure.

Place the ſocket, which is at the bottom of the opaque ſtage, on the bar Q X T, ſo that the concave mirror *o* may be next the end D E of the wooden body.

Screw the tubes P, O, into the end D E. The magnifier you intend to uſe is to be ſcrewed on the end O of theſe tubes.

The handle G *b*, or the milled nut (*fig.* 5.), muſt be placed on the ſquare end of the pinion *a*.

Place the lamp lighted before the glaſs lump *n*, and the object you intend to examine between the ſpring-plates of the ſtage; and the inſtrument is ready for uſe.

In all microſcopes there are two circumſtances, which muſt be particularly attended to: firſt, the modification of the light, or the proper quantity to illuminate the object; ſecondly, the adjuſtment of the inſtrument to the focus of the glaſſes and eye of the obſerver. In the uſe of the lucernal microſcope there is a third circumſtance, which is, the regulation of the guide for the eye.

1. To throw the light upon the object. The flame of the lamp is to be placed rather below the centre of the glaſs lump *n*, and as near it as poſſible; the concave mirror *o* muſt be ſo inclined and turned as to receive the light from the glaſs lump, and reflect it thence upon the object: the beſt ſituation of the concave mirror and the flame of the lamp depends on a combination of circumſtances, which a little practice will diſcover.

2. To regulate the guide for the eye, or to place the centre of the eye-piece L ſo that it may coincide with the focal point of the lenſes and the axis of viſion: Lengthen and ſhorten the tubes M, N, by drawing out or puſhing in the inner tube, and raiſing or depreſſing the eye-piece M L, till you find the large lens (which is placed at the end A B of the wooden body) filled by an uniform field of light, without any priſmatic colours round the edge; for till this piece is properly fixed, the circle of light will be very ſmall, and only occupy a part of the lens: the eye muſt be kept at the centre of the eye-piece L, during the whole of the operation; which may be rendered ſomewhat eaſier to the obſerver, on the firſt uſe of the inſtrument, if he hold a piece of white paper parallel to the large lens, removing it from or bringing it nearer to them till he find the place, where a lucid circle, which he will perceive on the paper, is brighteſt and moſt diſtinct; then he is to fix the centre of the eye-piece to coincide with that ſpot; after which a very ſmall adjuſtment will ſet it perfectly right.

3. To adjuſt the lenſes to their focal diſtance. This is effected by turning the pinion *a*, the eye being at the ſame time at the eye-piece L. The grey glaſs is often placed before the large lenſes, while regulating the guide for the eye, and adjuſting for the focal diſtance.

If the obſerver in the proceſs of his examination of an object, advance rapidly from a ſhallow to a deep magnifier, he will ſave himſelf ſome labour by pulling out the internal tube at O.

The upper part *f g r s* of the ſtage is to be raiſed or lowered occaſionally, in order to make the centre of the object coincide with the centre of the lens at O.

To

To delineate objects, the grey glass must be placed before the large lenses; the picture of the object will be formed on this glass, and the outline may be accurately taken by going over the picture with a pencil.

The opaque part may be used in the day-time without a lamp, provided the large lenses at A B are screened from the light.

To use the Lucernal Microscope in the Examination of transparent Objects.—The instrument is to remain as before: the upper part *f g s* of the opaque stage must be removed, and the stage for transparent objects, represented at *fig.* 6, put in its place; the end 9 10 to be next the lamp.

Place the greyed glass in its groove at the end A B, and the objects in the slider-holder at the front of the stage; then transmit as strong a light as you are able on the object, which you will easily do by raising or lowering the lamp.

The object will be beautifully depicted on the grey glass: it must be regulated to the focus of the magnifier, by turning the pinion *a*.

The object may be viewed either with or without the guide for the eye. A single observer will see an object to the greatest advantage by using this guide, which is to be adjusted, as we have described above. If two or three wish to examine the object at the same time, the guide for the eye must be laid aside.

Take the large lens out of the groove, and receive the image on the grey glass; in this case, the guide for the eye is of no use: if the grey glass be taken away, the image of the object may be received on a paper screen.

Take out the grey glass, replace the large lenses, and use the guide for the eye; attend to the foregoing directions, and adjust the object to its proper focus. You will then see the object in a blaze of light almost too great for the eye, a circumstance that will be found very useful in the examination of particular objects. The edges of the object in this mode will be somewhat coloured: but as it is only used in this full light for occasional purposes, it has been thought better to leave this small imperfection, than, by remedying it, to sacrifice greater advantages; the more so, as this fault is easily corrected, and a new and interesting view of the object is obtained, by turning the instrument out of the direct rays of light, and permitting them to pass through only in an oblique direction, by which the upper surface is in some degree illuminated, and the object is seen partly as opaque, partly as transparent. It has been already observed, that the transparent objects might be placed between the slider-holders of the stage for opaque objects, and then be examined as if opaque.

Some transparent objects appear to the greatest advantage when the lens at 9 10 is taken away; as, by giving too great a quantity of light, it renders the edges less sharp.

The variety of views which may be taken of every object, by means of the improved lucernal microscope, will be found to be of great use to an accurate observer: it will give him an opportunity of correcting or confirming his discoveries, and investigating those parts in one mode which are invisible in another.

To throw the Image of transparent Objects on a Screen, as in the Solar Microscope.—It has been long a microscopical desideratum, to have an instrument by which the image of transparent objects might be thrown on a screen, as in the common solar microscope: and this not only because the sun is so uncertain in this climate, and the use of the solar microscope requires confinement in the finest part of the day, when time seldom hangs heavy on the mind; but as it also affords an increase of pleasure, by displaying its wonders to several persons at the same instant, without the least fatigue to the eye. This purpose is now effectually answered, by affixing the transparent stage of the lucernal to a lanthorn, with one of Argand's lamps.—The lamp is placed within the lanthorn, and the end 9 10 of the transparent stage is screwed into a female screw, which is rivetted in the sliding part of the front of the lanthorn; the magnifying lenses are to be screwed into the hole represented at 12, and they are adjusted by turning the milled nut. The quantity of light is to be regulated by raising and lowering the sliding plate or the lamp.

Apparatus which usually accompanies the improved Lucernal Microscope.—The stage for opaque objects, with its semicircular lump of glass, and concave mirror. The stage for transparent objects, which fits on the upper part of the foregoing stage. The sliding tube, to which the magnifiers are to be affixed: one end of these is to be screwed on the end D of the wooden body; the magnifier in use is to be screwed to the other end of the inner tube. There are eight magnifying lenses, so constructed, that they may be combined together, and thus produce a very great variety of magnifying powers. A fish-pan, such as is represented at *Plate* XIV. *fig.* 8. A steel wire, with a pair of nippers at one end, and a small cylinder of ivory at the other. (*Plate* XIV. *fig.* 7.) A slider of brass, containing a flat glass slider, and a brass slider, into which are fitted some small concave glasses. A pair of forceps. Six large, and six small ivory sliders, with transparent objects. Fourteen wooden sliders, with four opaque objects in each slider; and two spare sliders. Some capillary tubes for viewing small animalcula. One of the improved Argand lamps, which are the most suitable for microscopic purposes, either with this or any other instrument, on account of the clearness, intensity, and steadiness of the light. A description of its structure will be found under the article LAMP.

The Microscope for opaque objects was also invented by M. Lieberkuhn about the same time with the former, and remedies the inconvenience of having the dark side of an object next the eye; for by means of a concave speculum of silver, highly polished, in whose centre a magnifying lens is placed, the object is so strongly illuminated, that it may be examined with ease. A convenient apparatus of this kind, with four different speculums and magnifiers of different powers, was brought to perfection by Mr. Cuff. Phil. Trans. N° 458. § 9.

The several parts of this instrument, made either of brass or silver, are as follows:

Through the first side A (*Plate* XV. *fig.* 7.) passes a fine screw B, the other end of which is fastened to the moveable side C.—D is a nut adapted to the said screw, by the turning of which the two sides A, C, are gradually brought together.—E is a spring of steel, that separates the said two sides when the nut is unscrewed.—F, a piece of brass turning round in a socket, whence proceeds a small spring tube moving upon a rivet, through which tube there runs a steel wire, one end of which terminates in a sharp point G, and the other hath a pair of plyers, H, fastened to it.—The point and plyers are to thrust into or take up and hold any insect or object: and either of them may be turned upwards, as suits your purpose best.—I, a ring of brass with a female screw within it, mounted on an upright piece of the same metal, which turns round on a rivet, that it may be set at a due distance when the least magnifiers are employed.—This ring receives the screws of all the magnifiers.—K, a concave speculum of silver, polished as bright as possible, in the centre of which a double convex lens is placed, with a proper aperture to look through it. On the back of this speculum a male screw,

ſcrew, L, is made fit to the braſs ring I to ſcrew into the ſaid ring at pleaſure.

There are four of theſe concave ſpecula, of different depths, adapted to four glaſſes of different magnifying powers, to be uſed as objects to be examined may require. The greateſt magnifiers are known by having the leaſt apertures. M, a round object-plate, one ſide white and the other black, intended to render objects the more viſible, by placing them, if black upon the white, and if white on the black ſide. A ſteel ſpring N turns down on each ſide to make any object faſt; and iſſuing from the object-plate is a hollow pipe, to ſcrew it on the needle's point G.—O, a ſmall box of braſs, with a glaſs on each ſide, contrived to confine any living object, in order to examine it: this alſo has a pipe to ſcrew upon the end of the needle G.—P, a turned handle of wood, to ſcrew into the inſtrument when it is made uſe of.—A pair of braſs plyers accompanies this inſtrument to take up any object, or manage it with conveniency: and a ſoft hair bruſh, to clean the glaſſes or ſpecula, or apply a drop of any liquid to the iſinglaſs of the box O, in order to view the animalcules.—Alſo, a ſmall ivory box for iſinglaſſes, to be placed, when wanted, in the ſmall braſs box O.

When you would view any object, ſcrew the ſpeculum, with the magnifier you think beſt to uſe, into the braſs ring I. Place your object either on the needle G, in the plyers H, on the object-plate M, or in the braſs hollow box O, as may be moſt convenient, according to the nature and condition of it: then holding up your inſtrument by the handle P, look againſt the light, through the magnifying lens, and by means of the nut D, together with the motion of the needle, by managing its lower end the object may be turned about, raiſed, or depreſſed, brought nearer the glaſs, or put farther from it, till you hit the true focal diſtance, and the light be ſeen reflected from the ſpeculum ſtrongly upon the object: by which means it will be ſhewn in a manner ſurpriſingly diſtinct and clear. And for this purpoſe the light of the ſky, or of a candle, will anſwer to your ſatiſfaction.

This microſcope is principally intended for opaque objects, but tranſparent ones may alſo be viewed by it: obſerving only, that when ſuch come under examination, it will not always be proper to throw on them the light reflected from the ſpeculum: for the light tranſmitted through them, meeting the reflected light, may, together, produce too great a glare. A little practice will teach how to regulate both theſe lights to good advantage. For an account of microſcopes attached to aſtronomical inſtruments, and deſigned for aſſiſting the obſerver to read off minute diviſions; ſee CIRCLE.

MICROSCOPIC OBJECTS. All things too minute to be viewed diſtinctly by the naked eye, are proper objects for the microſcope. Dr. Hooke has diſtinguiſhed them to be exceeding ſmall bodies, exceeding ſmall pores, or exceeding ſmall motions.

Exceeding ſmall bodies muſt either be the parts of larger bodies, or things, the whole of which is exceedingly minute, ſuch as ſmall ſeeds, inſects, ſalts, ſands, &c.

Exceeding ſmall pores are the interſtices between the ſolid parts of bodies, as in ſtones, minerals, ſhells, &c. or the mouths of minute veſſels in vegetables, or the pores in the ſkin, bones, and other parts of animals.

Exceeding ſmall motions are the movements of the ſeveral parts or members of minute animals, or the motion of the fluids, contained in either animal or vegetable bodies. Under one or other of theſe three heads, almoſt every thing about us affords us matter of obſervation, and may conduce both to our amuſement and inſtruction.

An examination of theſe objects, however, ſo as to diſcover truth, requires a great deal of attention, care, and patience, with ſome ſkill and dexterity, to be acquired chiefly by practice, in the preparing, managing, and applying them to the microſcope.

Whatever object offers itſelf as the ſubject of our examination, the ſize, contexture, and nature of it, are firſt to be conſidered, in order to apply it to ſuch glaſſes, and in ſuch a manner as may ſhew it beſt. The firſt ſtep ſhould always be to view the whole together, with ſuch a magnifier as can take it in all at once, and after this the ſeveral parts of it may the more fitly be examined, whether remaining on the object, or ſeparated from it. The ſmaller the parts are which are to be examined, the more powerful ſhould be the magnifiers employed; the tranſparency or opacity of the object muſt alſo be conſidered, and the glaſſes employed accordingly ſuited to it; for a tranſparent object will bear a much greater magnifier than one which is opaque, ſince the nearneſs that a glaſs muſt be placed at, unavoidably darkens an object if in its own nature opaque, and renders it very difficult to be ſeen, unleſs by the help of the apparatus contrived for that purpoſe, which has a ſilver ſpeculum. Moſt objects, however, become tranſparent by being divided into extremely thin parts.

The nature of the object alſo, whether it be alive or dead, a ſolid or a fluid, an animal, a vegetable, or a mineral ſubſtance, muſt likewiſe be conſidered, and all the circumſtances of it attended to, that we may apply it in the moſt advantageous manner. If it be a living object, care muſt be taken not to ſqueeze or injure it, that we may ſee it in its natural ſtate and full perfection. If it be a fluid, and that too thick, it muſt be diluted with water; and if too thin, we ſhould let ſome of its watery parts evaporate. Some ſubſtances are fitteſt for obſervation when dry, others when moiſtened; ſome when freſh, and others after they have been kept ſome time.

Light is the next thing to be taken care of; for on this the truth of all our obſervations depends; and a very little obſervation will ſhew how very different objects appear in one degree of it to what they do in another: ſo that every new object ſhould be viewed in all degrees of light, from the greateſt glare of brightneſs to perfect obſcurity, and that in all poſitions to each degree, till we hit upon the certain form and figure of it. In many objects it is very difficult to diſtinguiſh between a prominency and a depreſſion, a black ſhadow, and a black ſtain, and in colour between a bright reflection and whiteneſs. The eye of a fly, in one kind of light, appears like a lattice drilled full of holes; in the ſunſhine like a ſolid ſubſtance, covered with golden nails; in one poſition like a ſurface covered with pyramids, in another with cones, and in others with ſtill different ſhapes.

The degree of light muſt always be ſuited to the object; if that be dark, it muſt be ſeen in a full and ſtrong light, but if tranſparent, the light ſhould be proportionably weak: for which reaſon there is a contrivance both in the ſingle and double microſcope to cut off abundance of the rays, when ſuch tranſparent objects are to be examined by the largeſt magnifiers. The light of a candle for many objects; and eſpecially for ſuch as are very bright and tranſparent, and very minute, is preferable to day-light; for others a ſerene day-light is beſt; but ſun-ſhine is the worſt light of all, for it is reflected from objects with ſo much glare, and exhibits ſuch gaudy colours, that nothing can be determined from it with any certainty. This, however, is not to be extended to the ſolar, or camera obſcura microſcope; for in that nothing but ſun-ſhine can do, and the brighter that is, the better; but in that way we do not ſee the object itſelf on which

which the sun-shine is cast, but only the image or shadow of it exhibited on a screen; and therefore no confusion can arise from the glaring reflection of the sun's rays from the object to the eye, which is the case in other microscopes. But then in that solar way we must rest contented with viewing the true form and shape of an object, without expecting to find its natural colour; since no shadow can possibly wear the colour of the body it represents.

Most objects require also some management, in order to bring them properly before the glasses. If they are flat and transparent, and such as will not be injured by pressure, the best way is to enclose them in sliders between two Muscovy talcs or isinglass. In this way the feathers of butterflies, the scales of fishes, and the farinæ of flowers, may be very conveniently preserved, as also the parts of insects, the whole bodies of minute ones, and a great number of other things. These are to be kept in sliders, each containing three, four, or more holes, and these must not be filled promiscuously; but all the things preserved in one slider should be such as require one and the same magnifying power to view them, that there may not be a necessity of changing the glasses for every object; and the sliders should be marked with the number of the magnifier it is proper to be viewed with. In placing the objects in the sliders, it is always proper to have a small magnifier, of about an inch focus, in your hand, to examine and adjust them by, before they are fixed down with the rings.

Small living objects, such as lice, fleas, bugs, mites, minute spiders, &c. may be placed between these talcs without injuring them, if care be taken to lay on the brass rings without pressing them down, and they will remain alive many weeks in this manner; but if they are too large to be treated thus, they should be either preserved between two concave glasses, or else viewed immediately, by holding them in the pliers, or sticking them on the point at the other end of that instrument.

If fluids come under examination, to discover the animalcules in them, a small drop is to be taken with a hair-pencil; or on the nib of a clean pen, and placed on a plate of glass; and if they are too numerous to be thus seen distinctly, some water warmed, by holding it in the mouth, must be added to the drop, and they will then separate, and be seen distinctly. This is particularly necessary in viewing the animalcules in the *semen masculinum* of all creatures; which, though extremely minute, are always so numerous, that without this caution their true form can seldom be seen. But if we are to see the salts in a fluid, the contrary method must be observed, and the plate of glass must be held gently over the fire, till part of the liquor is evaporated.

The dissection of minute animals, as lice, fleas, &c. requires patience and care; but it may be done very accurately by means of a needle and a fine lancet, placing the creature in a drop of water, for then the parts will readily unfold themselves, and the stomach, guts, &c. be very distinctly seen.

These seem the best ways of preserving transparent objects; but the opaque ones, such as seeds, woods, &c. require a very different treatment, and are best preserved and viewed in the following manner.

Cut cards into small slips about half an inch long, and a tenth of an inch broad; wet these half way of their length in gum-water, and with that fasten on several pieces of the object, and as the spots of cards are of different colours, such should be chosen for every object as are the most different from its own colours. These are very convenient for viewing by the microscope made for opaque objects with the silvered speculum; but they are proper for any microscope that can view opaque bodies.

A small box should be contrived for these slips, with little shallow holes for the reception of each; and this is conveniently done, by cutting pieces of paste-board, such as the covers of books are made of, to the size of the box, so that they will just go into it, and then cutting holes through them with a small chissel, of the shape of the slips of card, these paste-boards having then a paper pasted over their bottom, are cells very proper for the reception of these slips, which may be taken out by means of a pair of plyers, and will always be ready for use.

Great caution is to be used in forming a judgment on what is seen by the microscope, if the objects are extended or contracted by force or dryness.

Nothing can be determined about them, without making the proper allowances; and different lights and positions will often shew the same object as very different from itself. There is no advantage in any greater magnifier than such as is capable of shewing the object in view distinctly; and the less the glass magnifies, the more pleasantly the object is always seen.

The colours of objects are very little to be depended on, as seen by the microscope; for their several component particles being by this means removed to great distances from one another, may give reflections very different from what they would, if seen by the naked eye.

The motions of living creatures also, or of the fluids contained in their bodies, are by no means to be hastily judged of, from what we see by the microscope, without due consideration; for as the moving body, and the space in which it moves, are magnified, the motion must be so too; and therefore that rapidity with which the blood seems to pass through the vessels of small animals must be judged of accordingly. Suppose, for instance, that a horse and a mouse move their limbs exactly at the same time, if the horse runs a mile while the mouse runs fifty yards; though the number of steps are the same in both, the motion of the horse must notwithstanding be allowed the swiftest; and the motion of a mite, as viewed by the naked eye, or through the microscope, is perhaps not less different. Baker's Microscope, p. 52. 62. Adams on the Microscope. See ANIMALCULES and *Plates of* MICROSCOPIC *Objects*.

MICROSTEMMA, in *Botany*, from μικρος, *small*, and στεμμα, *a crown*, alluding to the sort of coronet which accompanies the anthers.—Brown Tr. of the Wern. Soc. v. 1. 25. Prodr. Nov. Holl. v. 1. 459.—Class and order, *Pentandria Digynia*. Nat. Ord. *Contortæ*, Linn. *Apocineæ*, Juss. *Asclepiadeæ*, Brown.

Ess. Ch. Corolla wheel-shaped, five-cleft. Crown of the stamens of one leaf, fleshy, with five lobes, alternate with the anthers, which are without any membranous point. Masses of pollen attached laterally by the middle, lying over the stigma, which is pointless. Follicles slender, smooth. Seeds comose.

1. M. *tuberosum*. Br.—Native of New Holland, within the tropic. A smooth upright perennial herbaceous plant, with a tuberous *root*. *Stem* simple in the lower part, and furnished with minute leaves; branched above. *Leaves* opposite, linear. *Umbels* lateral and terminal, nearly sessile. *Corolla* blackish-purple, bearded at the inside.

MICROTEA, named by Professor Swartz, from μικροτης, *smallness*, on account of the parts of fructification being extremely minute, compared with others of its natural order. —Swartz Prod. 53. Ind. Occ. 542. Schreb. 797. Willd. Sp. Pl. v. 1. 1309. Mart. Mill. Dict. v. 3. Lamarck Illustr.

Illuftr. t. 182. Clafs and order, *Pentandria Digynia.* Nat. Ord. *Holeraceæ*, Linn. *Atriplices*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of five, oblong, permanent leaves. *Cor.* none. *Stam.* Filaments five, thread-fhaped, the length of the calyx, inferted into the receptacle; anthers rather globofe. *Pift.* Germen fuperior, roundifh, echinated; ftyles two, very fhort, divaricated; ftigmas fimple. *Peric.* a dry, leathery, flender drupa, befet with prickles. *Seed*, a roundifh, fmooth nut, with a fingle kernel.

Eff. Ch. Calyx of five leaves, fpreading. Corolla none. Drupa dry and prickly. Seed roundifh, covered with a leathery, echinated bark.

1. M. *debilis.* Willd. n. 1. Swartz Ind. Occ. t. 12.—(Schollera; Rohr Act. Soc. Hafn. v. 2. p. 1. 210.)—A native of feveral of the Weft India iflands.—The whole plant is fmooth, and about a foot in height. *Stem* herbaceous, branched, diffufe, nearly erect, ftriated. *Branches* irregular, diverging, weak, fpreading. *Leaves* alternate, on ftalks, ovato-lanceolate, pointed, entire, nerved, veinlefs, rather fucculent, and of a dark green colour. *Flower-ftalks* terminal or lateral, oppofite to the leaves, each bearing two, flender, rather clofe. *Clufters* of numerous, nearly upright *flowers*, moftly directed one way, on feparate, fhort ftalks, very minute, greenifh-white. Bracteas lanceolate, pellucid. *Drupa* the fize of muftard-feed, with very minute, prickly-edged cells all over the furface. *Nut* black and fhining; or it may be confidered as a *feed* covered with a leathery, prickly, or muricated bark.

Mr. Van Rohr, in the Copenhagen Tranfactions, named this plant which was communicated to him by Jacquin, *Schollera*, in honour of the author of *Flora Barbienfis.*

MICROTIS, fo named by Mr. Brown, from μικρος, *fmall*, and ους, ωτος, *an ear*, alluding to a pair of minute ear-like appendages to the anther. Brown Prodr. Nov. Holl. v. 1. 320.—Clafs and order, *Gynandria Monandria.* Nat. Ord. *Orchideæ.*

Gen. Ch. *Cal.* Perianth three-leaved, ringent; its two fide-leaves feffile, nearly oppofite to the lip. *Cor.* Petals two, much like the calyx, afcending. Nectary a lip proceeding from the lower part of the ftyle, oblong, obtufe, fpreading, callous at the bafe. *Stam.* Anther an hemifpherical, moveable, terminal lid, of two cells, attached to the pofterior edge of the top of the ftyle, permanent, accompanied by a membranous auricle at each fide; maffes of pollen two in each cell, powdery, affixed by their bafe to the ftigma. *Pift.* Germen inferior, obovate, erect, furrowed; ftyle erect, funnel-fhaped; ftigma in front. *Peric.* Capfule of one cell. *Seeds* numerous, minute.

Eff. Ch. Calyx ringent, its fide-leaves nearly oppofite to the lip. Petals afcending. Lip without a fpur, obtufe, callous at the bafe. Anther a lid, terminating the ftyle behind. Pollen powdery.

Five fpecies of this new genus were found by Mr. Brown in New Holland, chiefly in the colder parts, and a fifth is our *Epipactis unifolia.* (See Epipactis.) The *bulbs* are undivided and naked. *Herbage* fmooth. *Leaf* folitary, cylindrical, fiftulous, embracing the ftem with its long fheathing bafe. *Spike* of many fmall, greenifh or white, *flowers*, the *lip* of fome of which is undivided, in others two-lobed. The leaves of the *calyx*, as well as the petals, are more or lefs linear, the former frequently revolute. The *lip* differs greatly in form in the different fpecies, and its margin is in fome even and naked, in others wavy, warty, or tuberculated. The appearance of the whole is obferved by Mr. Brown to be very different from *Epipactis*, and moft like another genus of his own, named *Prafophyllum.*

MICTUS Cruentus. See *Bloody* Urine.

MID, or Middle, in *Philofophy* and *Mathematics.* See Mean and Medium.

MIDA, in *Natural Hiftory*, the name of a worm or maggot, of which is produced the purple fly, found on bean-flowers, and thence called the bean-fly.

MIDAD Alhendi, in the *Materia Medica of the Arabians*, a name given to the common indigo blue.

The exprefs meaning of the words is India ink; but this is an erroneous name, founded on Pliny's mifunderftanding the words of Diofcorides.

MIDAS, in *Fabulous Hiftory* and *Mythology*, was, according to Paufanias, the fon of Gordius and Cybele, and reigned in the Greater Phrygia, as we learn from Strabo. According to the former of the two authors, he built the city of Ancyra, and that of Peffinus, upon mount Agdiftis, famed for the tomb of Atys; but the latter merely fays, that he and Gordius his father fixed their refidence near the river Sangar, in cities, which in his time were mean villages: as he was rich, and a great economift, it was fabled that he turned into gold whatever he touched. It is fuggefted that this fable took its rife from his having been the firft who difcovered gold in the Pactolus. From his infancy it was forefeen, that he would be very rich and very frugal, becaufe the ants, approaching his cradle, had put grains of corn into his mouth. However, his talent for accumulation did not extend to the acquirement of tafte and knowledge in the fine arts; and, perhaps, his dulnefs and inattention to thefe, provoked fome mufical poet to invent the fable of his decifion in favour of Pan againft Apollo.

Pan, who thought he excelled in playing the flute, offered to prove that it was an inftrument fuperior to the lyre of Apollo. The challenge was accepted, and Midas, who was appointed the umpire in this conteft, deciding in favour of Pan, was rewarded by Apollo, according to the poets, with the ears of an afs, for his ftupidity.

The fcholiaft upon Ariftophanes, for explaining the fiction of the affes' ears, which Apollo had prefented to Midas, fays that it was defigned to intimate that he had a very fine ear, like that animal, or becaufe he kept fpies through all his dominions, or becaufe he commonly dwelt in a place named ωτα ονε, the affes' ears. The fable reports, that his power of converting whatever he touched into gold was given him by Bacchus; but the prefent foon became injurious to him; for it is faid, that whilft he was waiting for his dinner, the water in which he wafhed his hands, and alfo the bread, wine, and meat that were ferved up to him, were converted into gold, when he was ready to ftarve amidft all his riches: but applying to Bacchus, with a requeft that he would revoke the grant, Bacchus ordered him to wafh his hands in the Pactolus, by which act he transferred the virtue which he poffeffed to the river, which, from that time, rolled a golden fand. This fable is thus explained. Midas, frugal to avarice, reigned over a very rich country, and made confiderable fums by the fale of his corn, wine, and cattle. His avarice afterwards changed its object, and having learned that the Pactolus furnifhed gold duft, he abandoned the care of the country, and employed his fubjects in gathering the gold of that river, which brought him a new and ample fupply. On account of his attention to religion among the Lydians, he was reckoned, according to Juftin, a fecond Numa.

Midas's *Ear-fhell*, in *Conchology.* See Trumpet-*Fifh.*

MIDDATOOR, in *Geography*, a town of Hindooftan, in Golconda; 15 miles S.E. of Canoul.

MIDDEL-

MIDDELBURG, a sea-port town of Holland, in the state of Zealand, situated in the centre of Walcheren, of which it is the capital. The town-house is a magnificent building; and the fortifications are strong and regular, with eight gates, and twelve bastions for defending the walls and ramparts, besides large and deep ditches filled with water; and such also is its situation, that the inhabitants may lay the country under water whenever they please. The number of inhabitants has been estimated at about 26,000. N. lat. 51° 34'. E. long. 3° 29'.

MIDDING, in *Agriculture*, a provincial term applied to a dunghill.

MIDDLE BANK, in *Geography*, one of the fishing banks of Newfoundland; S.E. of Cape Breton. N. lat. 45°. See FISHERY.

MIDDLE *Cape*, lies to the south-west of cape Anthony, in Staten Land, on the strait Le Maire, and the most westerly point of that island; at the extremity of South America.

MIDDLE *Island*, a small island in the straits of Salayer, near the south coast of Celebes. S. lat. 5° 40. E. long. 120° 52'.—Also, a small island in the East Indian sea, near the south-west coast of Boulton. S. lat. 5° 38'. E. long. 123° 50'.—Also, an island in the straits of Sunda, in the Indian sea. N. lat. 5° 57'. E. long. 104° 53'.—Also, a small island in Upper Canada, east of the Bass islands, and north of Ship island and Cunningham's island, in lake Erie.

MIDDLE *Islands*, a cluster of small islands in lake Huron. N. lat. 45° 1'. W. long. 83° 33'.—Also, a cluster of small islands in the Pacific ocean, near the coast of Mexico. N. lat. 9° 30'.

MIDDLE *Island Creek*, a river of Virginia, which runs into the Ohio, N. lat. 39° 16'. W. long. 81° 22'.

MIDDLE *Lake*, a lake of Canada; 300 miles N. of Quebec. N. lat. 51° 44'. W. long. 69° 35'.

MIDDLE *Latitude*, in *Navigation*, is half the sum of two given latitudes.

MIDDLE *Latitude sailing*, is used for a method of working the several cases in sailing, nearly agreeing with Mercator's way, but without the help of meridional parts. See SAILING.

MIDDLE *Point*, in *Geography*, a cape on the east coast of Labrador. N. lat. 59°. W. long. 63°.

MIDDLE *Region*. See REGION.

MIDDLE *Sister*, in *Geography*, a small island at the west end of lake Erie, in Upper Canada, situated between the East and West Sister.

MIDDLE *States*, one of the grand divisions of the United States of America, comprehending New York, New Jersey, Pennsylvania, Delaware, Ohio, and Indiana.

MIDDLE *Teint*, in *Painting*. See HALF-TEINT.

MIDDLE *Voice*, in the *Greek Language*, holds an intermediate rank between the Active and the Passive, being supposed to have a middle signification between them. Its tenses are formed partly on the model of the Active, and partly on that of the Passive tenses. The tenses peculiar to the middle voice are the two futures, the two aorists, the perfect, and the pluperfect. The two futures and the two aorists borrow the terminations of the Passive, while the two perfect tenses borrow those of the Active voice. For the manner in which these tenses are formed, we refer to the valuable Grammar of the Greek Tongue, on a new and improved plan, by Mr. John Jones. This excellent grammarian also observes, that as the middle voice derives its origin and explanation from the Passive, it is frequently used, like a Passive verb, in a sense purely active, and has after it an accusative noun; and this usage abounds in all writers of prose as well as poetry. It is further observed, that when an accusative noun is not annexed, the personal pronoun, combined with the verb in the oblique case, is the object of the verb. Hence it is that the middle verb expresses a reciprocal or reflex sense. Our author infers from this statement, that the middle verb is in the strictest sense an Active verb; but whether or not it conveys a reflex signification, depends on the circumstance whether an accusative noun be annexed or not. The presence of a noun in the accusative, causes, as it were, the combined pronoun to disappear, and the verb becomes purely active; while its absence gives room for the objective pronoun to display itself, which consequently assigns to the verb the character of "reflex." Although the middle verb contains an objective pronoun in itself, yet it is sometimes distinctly annexed, in order to render the meaning more emphatic or prominent. Sometimes a noun equivalent to the reflex pronoun is annexed to a middle verb. For the illustration of these remarks by apposite examples, we refer to the author himself, *ubi supra*.

MIDDLE *Wales*, in a *Ship*, two or three thick strakes wrought fore and aft, between the lower and middle deck-ports, in three-deck ships.

MIDDLEBOROUGH, in *Geography*, the Namaskett of the ancient Indians, a post-town in Plymouth county, Massachusetts, incorporated in 1669, and containing 4458 inhabitants; 40 miles S. by E. of Boston. This town is remarkable for a large range of ponds, which produce several sorts of fish, and large quantities of iron ore.

MIDDLEBOURG KEY, a small islet, separated from St. Martin's in the West Indies, on the north-east.

MIDDLEBROOK, a post-town of America, in Augusta county, Virginia; 186 miles from Washington.

MIDDLEBURG, a post-town of America, in Lowden county, Virginia; 47 miles from Washington.—Also, a post-town of Nelson county, Kentucky; 603 miles from Washington.

MIDDLEBURG, a town of Flanders, which derived its name from an abbey called "Middleburg," to which it belonged. In this town the free exercise of the Roman Catholic religion is allowed; 7 miles N.E. of Bruges. N. lat. 51° 16'. E. long. 3° 15'.

MIDDLEBURG. See EA-OO-WEE.

MIDDLEBURG, *New*, a town of Dutch Guiana, at the extremity of the colony.

MIDDLEBURG, a small island near the west coast of New Guinea. S. lat. 0° 18'. E. long. 132° 32'.—Also, a small island in the gulf of Manar, near the west coast of Ceylon; 18 miles N. of Manar.

MIDDLEBURY, a post-town of America, in Vermont, capital of Addison county. Here are a brewery on a large scale, three grist mills, four saw mills, a forge, a gun and card manufactory, gaol, court-house, college, and about 400 dwelling-houses. The township lies on the east side of Otter creek, and contains 1263 inhabitants; 511 miles N.E. of Washington.

MIDDLEFAHRT, a town of Denmark, on the west coast of the island of Funen, in the Little Belt, which is here scarcely one mile wide, and called "Middlefahrt sound." Here is a ferry to Snogboy in Jutland; 34 miles W. of Odensee. N. lat. 55° 32'. E. long. 9° 39'.

MIDDLEFIELD, a township of America, in Hampshire county, Massachusetts; 30 miles N.W. of Springfield; incorporated in 1783, and containing 817 inhabitants.—Also, a thriving town in Trumbul county, state of Ohio; 15 miles N. of Warren.

MIDDLEHAM, a small market-town and parish in the wapentake

wapentake of Hang-Weſt, in the North Riding of the county of York, England, is ſituated on the ſouthern bank of the river Ure, 10 miles from Richmond, 44 from York, and 229 from London. Leland ſays, "The toun is ſet on a hille ſide. The greate hil above hit more then a mile of hit is cawllid Penhil, and is countid the hieſt hille of Richemontſhire. Middleham caſtle joynith harde to the toun ſide, and is the faireſt caſtel of Richemontſhire next Bolton, and the caſtel hathe a parke by hit caullid Sonſkne, and another cawllid Weſtpark, and the third caullid Gauneleſſe, half a mile of. Weſtparke and Gaunleſſe be well woddid. There is at the eſt ende of Midlcham a little hoſpital, with a chapel of Jeſus." The pariſh church is a handſome ſtructure. In the year 1476, Richard duke of Glouceſter (afterwards king Richard III.) obtained a licence from his brother, Edward IV., to make it collegiate, with proviſion for a dean, ſix chaplains, four clerks, and ſix choriſters; but the eſtabliſhment was never completed. The miniſter of the pariſh hath yet the title of dean of Middleham, and enjoys ſeveral privileges; but there probably never were any chaplains, clerks, or choriſters. The caſtle, now in ruins, was the birth-place of king Richard III.; and in it Edward IV. was confined, after having been taken priſoner in his camp by Nevill, earl of Warwick. Middleham contained, according to the return in the year 1801, under the population act, 154 houſes, and 728 inhabitants, of whom a conſiderable number are employed in the woollen manufacture. A weekly market is held on Monday, and here are three annual fairs.

MIDDLE-HORNED, in *Agriculture*, a term applied to an uſeful breed of neat cattle. This breed, which are often employed in team labour, is diſtinguiſhed by different characteriſtic marks in the different varieties; which, in the Devonſhire ſort, is by a high red colour without white ſpots, by a light dun ring round the eye, by the muzzle having the ſame colour, by being fine in the bone and clean in the neck, by the medium length of the horns, and their being turned upwards, by being thin-faced, fine in the chops, wide in the hips, with a tolerable barrel, rather flat on the ſides, by the tail being ſmall and ſet on high, by being thin-ſkinned and ſilky in handling, and by the property of fattening at an early age, or arriving quickly at maturity. They are admirably fitted for the purpoſe of draught in hardineſs, quick movement, and the form of the ſhoulder.

The principal varieties of this breed are the Devonſhire, the Suſſex, and the Herefordſhire; all of which are highly uſeful ſorts, and differ in ſome ſlight particulars from each other, as is ſeen under the head *Cattle*, where a full deſcription of each kind is given. See CATTLE.

MIDDLESEX, *Earl of*, in *Biography*. This nobleman is often mentioned in opera annals, from the year 1741, when Handel retired from the Haymarket theatre as manager, or *impreſario;* his lordſhip having taken upon himſelf that perilous and troubleſome office, perſevered in his love of dramatic muſic, and of rule, to his great loſs, till 1748. See OPERA *Hiſtory in England.*

MIDDLESEX, in *Geography*, an inland county of England, is bounded on the north by Hertfordſhire, on the ſouth by the river Thames, which divides it from Surrey, on the weſt by the river Colne, which ſeparates it from Buckinghamſhire, and on the eaſt by the river Lea, which divides it from Eſſex. Its ſhape is extremely irregular, but, on the whole, approaches to that of the quadrangle. The greateſt extent of the ſhire, from eaſt to weſt, meaſures about 20 miles; and its greateſt breadth, from north to ſouth, about 17 miles. The ſuperficial area of the whole county is eſtimated by Mr. Middleton, in his Agricultural Survey, at 280 ſquare miles, or 179,200 acres. Some other writers, however, ſtate its contents at 218,000 acres. According to the parliamentary returns of 1801, it contained 118,083 houſes, inhabited by 818,129 perſons, *viz.* 373,655 males, and 444,474 females, of whom 162,260 were ſtated to be employed in different branches of trade and manufactures, and in agriculture.

This county, before the Roman invaſion, formed part of the territories of the Trinobantes, or Trinovantes, a tribe of Britons, who are ſuppoſed to have derived their name from the peculiar nature of the country they occupied; being a broad valley on the banks of a wide ſpreading river. This tribe poſſeſſed two conſiderable cities, or fortified places; of which the eminence between the Thames and Moorfields, nearly the centre of modern London, was the ſcite of one; the other, and moſt important at that early period, was Camalodunum, now Colcheſter in Eſſex. Being torn by internal diſſentions, the Trinobantes were the firſt who found themſelves compelled to ſubmit to the Roman arms. After the complete ſubjugation of the iſland, their territories, and conſequently Middleſex, were included in the diviſion called Flavia Cæſarienſis; and Londinum or Auguſta, now London, became a principal Roman ſtation, though, from ſome cauſe unknown, it never was dignified with the name of a colony. See an intereſting account of the Roman ſtation and antiquities of London, by J. Moſer, eſq., in European Magazine for September 1812.

After the retreat of thoſe illuſtrious conquerors, and the eſtabliſhment of the Saxon heptarchy, this county appears for ſome time to have conſtituted a kingdom of itſelf; for which, however, its kings were obliged to do homage to thoſe of Kent or Mercia. It was ultimately incorporated with the kingdom of the Eaſt Saxons, and remained in that condition till the diſſolution of their monarchy, by the ſubjugation of the ſeveral kingdoms of the heptarchy to one monarch. Subſequent to this event, the hiſtory of London is intimately connected with the hiſtory of Middleſex. See Turner's Hiſtory of the Anglo-Saxons, 2 vols. 4to.

The ſurface of this county, though moſtly flat, preſents a variety of hills, near its union with Hertfordſhire, many of which riſe almoſt imperceptibly to their ſummits, and are, on that account, admirably adapted for the purpoſes of agriculture; being ſufficiently ſloping to ſecure a proper drainage, and, at the ſame time, free from abrupt elevations. This inequality of ſurface, moreover, contributes in no ſmall degree to health, ornament, and beauty; though only a few ſpots can be conſidered as eminently pictureſque. The ground, for the moſt part, aſcends from the banks of the Thames towards the north; and, within four miles of London, appears a range of gentle eminences, which ſhelters the metropolis from the northern blaſts, and agreeably breaks the uniformity of the horizon. Of theſe heights the chief are Hampſtead, Highgate, and Muſwell Hill; all of which afford many pleaſing and extenſive proſpects. So likewiſe does Harrow Hill, which, from riſing in a ſort of iſolated manner, forms a prominent object for many miles around. This eminence approaches a higher and more extenſive ridge, ſtretching north-eaſtward in interrupted ſwells from Pinner, Stanmore, Elſtree, Totteridge, and Barnet, to the foreſt ſcenery of Enfield Chace. The average elevation of theſe hills is about 400 feet above the ſtream of the Thames. Such land as lies contiguous to that river, and to the Colne and Lea, is in general perfectly level, and exhibits a ſtate of the higheſt cultivation.

The mineralogy of this county affords fewer objects of intereſt than perhaps any other in England. According to Mr.

Mr. Middleton, the diſpoſition of the ſtrata is, "firſt, cultivated ſurface; ſecondly, ſiliceous gravel, from five to ten feet in thickneſs; thirdly, a ſtrong leaden coloured earth, generally called clay, varying from one to three hundred feet in thickneſs; fourthly, marine ſediment, ſometimes cockle ſhells, but principally oyſters, agglutinated together, and hardened into a ſort of ſtony ſtratum, three, four, or five feet deep; fifthly, looſe ſand and gravel, from which the water is found to riſe in ſuch quantity, as to preclude the poſſibility of digging further. No metallic ſtrata have yet been diſcovered in any part of the county; and appearances indicate, that if there really are any ſuch, they lie at too great a depth to be made ſubject to the operations of the miner." A thin ſtratum of fullers' earth, however, was found, in 1802, about a mile from Paddington, on the Edgeware road; and in 1798, a quantity of looſe coal, twelve inches in thickneſs, was diſcovered at Chelſea, nearly fifty feet from the ſurface. Foſſil ſhells, principally bivalves, together with other marine exuviæ, have occurred in different parts.

The ſoils in Middleſex are various, but loam and clay, or ſand and gravel, more or leſs intermixed with loamy clay, are the moſt prevalent. The latter ſort of ſurface predominates on the ſummits of moſt of the hills. Hampſtead Hill conſiſts chiefly of yellow iron-ſtained ſand, with ſome loam and rounded flints placed on a pure white ſand, many feet in depth. A loamy ſand is the prevailing ſoil in that diſtrict of the county which forms its ſouth-weſternmoſt angle, and lies beeween the river Thames, and the road ſtretching from Hounſlow to Colnbrook. From Tottenham to Enfield Waſh the ſuper-ſtratum is of a ſimilar deſcription, and reſts upon the ſame under ſtrata. Weſtward from Hanwell and Hounſlow, the loam exiſting in much greater quantity than the ſand, agriculturiſts diſtinguiſh the ſoil here by the appellation of a ſandy loam. The ſame ſoil is found in the pariſhes of Twickenham, Iſleworth, Ealing, Chiſwick, Kenſington, Fulham, Brompton, and Chelſea, as likewiſe in the ſouth diviſion of the pariſh of Harefield. All the land from Ruiſlip and Ickenham on the weſt, to Gneeford, Apperton, and Harrow on the eaſt, and between Pinner on the north, and Northcote on the ſouth, is compoſed of ſtrong loam; the land about Muns is of the ſame kind, and the level between Iſlington, Hampſtead, and Hornſey, is a ſtrong but very unproductive loam. The loamy clay predominates on the north ſide of a hill between Uxbridge Common and Harefield, to the northweſt of Ruiſlip, and between the river Brent and Hampſtead on the Hendon road. From Nightingale Hall by Colney Hatch to Whetſtone, the ſoil is a loamy clay mixed with pebbles of flint, and alſo from Potters'-Bar for about two miles towards South Mims. The north ſide of Highwood Hill has a thin layer of loamy clay on a ſubſoil of yellow clay, every where abounding with rounded flints. In the Iſle of Dogs, and in all the lands on the flat borders of the rivers Lea and Colne, together with ſome ſpots immediately adjacent to the Brent and the Thames, the ſoil is of that peculiarly rich kind which is formed by the collection of the various ſubſtances that may be waſhed down by the rivers from the high grounds, villages, towns, and cities. The moors extending from Rickmanſworth to Staines conſiſt chiefly of peat on a ſubſoil of ſiliceous gravel, which in various parts ſhews itſelf at the ſurface. Some peat has likewiſe been found in the Iſle of Dogs.

Middleſex, from its ſituation with regard to London, preſents more variety in its agriculture than any county in Great Britain. To give the reader, therefore, a proper idea of this ſubject, it will be neceſſary to enter at greater length into detail than might otherwiſe be requiſite. In general, however, it may be premiſed that the eaſtern diviſion of the county, with the exception of the gardens in the vicinity of the metropolis, are appropriated to meadow, paſture, and potatoe-grounds; and that the weſtern diviſion, excepting Hounſlow Heath, Sunbury, and Ruiſlip commons, and ſome other ſpots, conſiſts chiefly of arable lands.

The greater part of the upland, meadow, and paſture-grounds in this county has, no doubt, been at one time under cultivation, as they ſtill exhibit unequivocal marks of the plough. Theſe grounds are kept in the higheſt ſtate of order, and are plentifully furniſhed with manure, ſo that they afford the moſt luxuriant crops. The manner and period of applying the manure are ſtudied by the farmers with great attention. They obſerve, ſays Mr. Middleton, the ſtate of the atmoſphere, and ſhould it indicate rain after the hay is removed from the ground, they put the dung of neat cattle upon it. Should the barometer, however, not promiſe rain in conſiderable quantities, the decompoſed manure is allowed to remain on the dunghills till the end of September, at which time it is put on while the ground is dry enough to bear the loaded carts without injury. Meadow land in the occupation of cow-keepers is uſually mown two or three times during ſummer, the great number of cows kept by them enabling them to dreſs it every year. As their chief object is to obtain their hay of a ſoft graſſy nature, they cut it young, conceiving it to be better provender for milk cows in that ſtate than after the ſeedling ſtems have riſen.

The paſturage or graſs-lands lie principally, if not entirely, on the banks of the ſeveral rivers with which this county is ſupplied. Thoſe adjoining to the river Lea contain about 2000 acres, of which upwards of 1200 are incloſed, and the remainder divided by land-marks among a great number of proprietors. The ſeveral tracts of graſs-lands on the banks of the Colne include about 2500 acres, and ſuch of them as are incloſed are extremely fertile. By far the greater proportion of them, however, are Lammas Meads; and one of the neceſſary conſequences of this condition is, that the ditches are ſo much neglected as to be grown up. The richeſt graſs-land in the whole county is that of the Iſle of Dogs, which, ſince the formation of the Eaſt India Docks, has been reduced from 1000 to leſs than 500 acres.

Before concluding the ſubject of meadow and graſs-lands, it may not be improper to notice ſhortly the method of haymaking practiſed in this county, the decided ſuperiority of the farmers in that art being acknowledged by all who have any pretenſions to agricultural ſkill. Here it is reduced to a regular ſyſtem, unknown in other parts of the kingdom. When the graſs is about to be mown, the farmer engages a certain number of perſons for that work, according to the extent of his lands. At the ſame time he provides five haymakers to each mower, who are paid by the day. On the firſt day all the graſs mown before nine o'clock is tedded, in which operation great care is taken to ſhake it out well, and ſtrew it evenly over the ground. After this, it is turned once or twice with ſimilar care; and in the courſe of the afternoon is raked into what are called ſingle wind rows, and towards the evening is put into graſs cocks. On the ſecond day the buſineſs commences by tedding all the graſs mown on the firſt day after nine o'clock, and all that has been mown this day before nine o'clock. Next the graſs cocks are well ſhaken out into ſeparate plats, called ſtaddles, of five or ſix yards diameter. The ſtaddles are next turned, and after that is done, the graſs tedded in the morning is turned once or twice in the ſame manner as deſcribed for the firſt day. After dinner the ſtaddles are

are formed into double wind rows; the grafs is next raked into fingle wind rows; then the double wind rows are put into baftard cocks; and laftly, the fingle wind rows are put into grafs cocks. On the third day the grafs mown and not fpread on the fecond day, and alfo that mown in the early part of this day, is firft tedded in the morning, and the grafs cocks are fpread into ftaddles, as before, and the baftard cocks into ftaddles of lefs extent. Thefe leffer ftaddles, though laft fpread, are firft turned, then thofe that were in the grafs cocks, and laftly, the grafs, once or twice; after which, the people go to dinner. Should the weather prove fine, the hay which was in baftard cocks the preceding night, will, this afternoon, be in a proper ftate to be carried, but not fo if the weather has been cloudy and cool. In the latter cafe, the firft operation after dinner is to rake the grafs cocks of the laft night into double wind rows, and the grafs which was this morning fpread from the fwaths into fingle wind rows. Afterwards, the baftard cocks of the laft night are made up into full fized cocks, and care taken to rake the hay up clean, and alfo to put the rakings upon the top of each cock. Next, the double wind rows are put into baftard cocks, and the fingle wind rows into grafs cocks, as on the preceding days. On the fourth day the great cocks are ufually carried before dinner. The other operations of the day are conducted in the fame routine as on thofe already defcribed, and fo on daily till the harveft is finifhed.

The fruit gardens of Middlefex, folely intended for the fupply of the public market, are fuppofed to occupy about 3000 acres. They extend, principally, on each fide of the high road, from Kenfington through the parifhes of Hammerfmith, Brentworth, Ifleworth, and Twickenham. Thefe gardens, on an average, furnifh conftant employment to about ten perfons *per* acre, men, women, and children; but during the fruit feafon, this number is increafed from thirty-five to forty. The annual produce of the labour of thefe individuals collectively is eftimated at 300,000*l.*, about three-fourths of the whole fupply of London. In thefe gardens it is ufual to have two crops, one called an *upper*, and the other an *under* crop. The former confifts of the larger fpecies of fruits, and the latter of the fmaller, fuch as rafpberries, goofeberries, currants, and others which are known to fuffer little injury by exclufion from the influence of the fun. Some gardens are inclofed by very high walls, againft which grow a vaft variety of wall fruits; and artificial banks are alfo frequently formed, by means of which the gardeners are enabled to raife certain crops many weeks earlier than they could otherwife effect.

The nurfery gardens lie moftly in the neighbourhoods of Chelfea, Brompton, Kenfington, Hackney, Dalfton, Bow, and Mile-End, and are computed to comprife upwards of 1500 acres. In thefe gardens are to be found almoft every variety of fruit trees, ornamental fhrubs, and rare plants, known in any quarter of the world. Indeed, fo celebrated are the nurfery-men of Middlefex for the cultivation of exotics, that, in times of peace, a great exportation of thefe articles takes place to France, Spain, Portugal, Italy, Ruffia, and other countries.

The extent of ground fituated in Middlefex appropriated to kitchen gardens for the fupply of the London markets, is eftimated at nearly 3000 acres, or about one-fourth of the whole lands fo employed in the neighbourhood of the metropolis. About a tenth part of thefe gardens is entirely prepared by the fpade, and the remainder partly by the fpade, and partly by the plough. The average produce of thefe gardens, which are kept in a ftate of high fertility by an abundant fupply of manure, is fuppofed to amount to 200*l.* *per* acre annually, the profit upon which may be about 120*l.* Willows for the ufe of the bafket-makers are much cultivated in the iflands and on the banks of the Thames, particularly in the vicinity of Brentford, Twickenham, and Sunbury. The profits arifing from this fpecies of cultivation are faid to be immenfe, but they are carefully concealed from public fcrutiny.

Farms in this county, from the manifold divifion of its landed property, are ufually of fmall extent. The rents vary extremely, according to local and other circumftances, being in fome places averaged fo low as ten fhillings, and in others at above twelve pounds. They are, without exception, paid in money, with the addition, in fome few inftances, of fupplying the landlord's family in town with frefh butter at 8*d.* or 9*d.* *per* pound, of 16 ounces to the pound, and with cream at 6*d.* *per* pint. Tithes, from which only a very few farms are free, are chiefly taken in kind, though in fome cafes an annual compofition is preferred. The wages of labourers in hufbandry here in winter vary from ten to twelve fhillings *per* week, and in fummer from twelve to fifteen. Thofe employed only in hay-time and harveft have from fifteen to eighteen fhillings, with beer occafionally, and fometimes a dinner. A great part of the agricultural bufinefs, however, is done by the piece, the prices varying according to the feafon. Farm-houfes, built within the laft hundred years, are moftly conftructed of brick, and well adapted for the accommodation of a refpectable family. The offices erected within the fame period are likewife laid out upon a good plan. If of older date, however, than the 18th century, both houfes and offices are of wood, lathed and plaiftered, with the roofs thatched; and from the many repairs, additions, and alterations they have undergone, have the appearance of being built by piece-meal, to fuit the immediate wants of the farmers, who may properly be divided into various claffes or defcriptions of perfons. Thofe who rent land in the immediate neighbourhood of the metropolis are chiefly cow-keepers, gardeners, and nurfery-men. The lands lying immediately behind their's are occupied by the villas of wealthy citizens and others; and thefe are fucceeded by farmers, who may be again divided, firft, into perfons with whom farming is but a fecondary occupation; and, fecondly, fuch as, having acquired an eafy fortune by other purfuits, retire to farming, with the idea of uniting profit and amufement in their agricultural labours. The third clafs is lefs numerous than either of the former, and confifts likewife of perfons who have abandoned fome former purfuit entirely, and directed their attention exclufively to farming as a profeffion: this clafs forms the moft intelligent and moft accurate of hufbandmen. The fourth and laft clafs is equal in number nearly to all the other claffes conjoined, and is compofed of perfons who have been originally bred to farming, and have continued to employ themfelves in the fame occupation.

The arable lands in Middlefex are chiefly fpread out in common fields, not above one-fourth of the whole being inclofed. This department of hufbandry is much lefs underftood than thofe divifions of it already noticed. Ploughing is, for the moft part, conducted upon an injurious and expenfive plan. The ploughs, as well as the carts, are much too clumfy, requiring an unneceffary number of cattle to drag them. Fallowing is feldom practifed, becaufe the farmers regard the introduction of green crops, at certain intervals in the rotation of crops, as rendering this mode of recruiting the ground altogether unneceffary; and it muft be confeffed, the idea derives fome confirmation from experience, for in the parifh of Hefton, where the beft wheat in the county is grown, that practice is wholly excluded. The

corn

corn chiefly raised here is wheat and barley, rye and oats being cultivated only in very small quantities. The whole extent of land cropped with wheat in Middlesex is about 10,000 acres, and new grain recently threshed is mostly preferred for seed. About 4000 acres are laid down in barley; 3000 acres are appropriated to beans; and nearly the same amount to peas. The remainder of the arable lands is occupied by a variety of other green crops, as turnips, cabbages, white and red clover, ray-grass, (usually cut green,) and tares for the food of cattle; together with turnips, potatoes, carrots, parsnips, &c. for the use of man. Liquorice and hops are likewise among the saleable commodities cultivated in a few fields in the vicinity of London.

The number of live stock kept in this county is smaller, even in proportion to its extent, than in any other in England, with the exception of the cows appropriated for the supply of London with milk. These cows, which are of a large size, are commonly distinguished by the appellation of the Holderness breed, from a district of that name in Yorkshire; but they have long since ceased to be confined to that particular kind. The total number kept in Middlesex, for the purpose above-mentioned, is stated by Mr. Foot, in his Agricultural Report, at 7200. The mode of treating these cattle is as follows. During the night they are confined to their stalls, and about three o'clock in the morning each is provided with half a bushel of grains. From four to half past six they are milked by the retail dealers, and as soon as that operation is finished, each cow receives a bushel of turnips, and not long afterwards a small portion of soft meadow hay. These several feedings are commonly finished by eight o'clock in the morning, when the cattle are turned into the cow-yard. At twelve, they are again confined to their stalls, and are served with the same quantity of grains which they had in the morning. The milking recommences about half past one, after which follows again the turnips and hay. This mode of feeding continues from the month of September to May. During the other months they are fed with grains, cabbages, tares, and second cut grass, except when the weather is peculiarly fine, and then they are turned out to graze; but even in this case they still receive a portion of grains. One bull is the usual proportion to a stock of thirty cows. The net profit of the cow-keeper, upon every cow, is estimated at 6*l.* annually. Calves are generally disposed of at one, two, or three days old. Many, however, are likewise suckled for eight or ten weeks, when they become fat, and are thought to furnish the best veal.

The Middlesex sheep are not of any particular breed, the farmers either directly or indirectly purchasing their stock from almost every county in England. Such ewes, however, as are kept for the supply of the London markets with house-lambs, are all of the Dorsetshire breed. This last branch of farming is, perhaps, the most profitable of any in the county. Early-lambing ewes, of which those of a large size with white noses are preferred, are sought for with great diligence, the prices varying from forty to fifty shillings. Early grass-lambs are likewise an object of importance with the farmers of Middlesex; and for supplying these, the Dorset ewes are chiefly selected, but the South-down breed is occasionally preferred. The feed both of the ewes and lambs is principally turnips and second crop hay. The lambs are usually sold fat in the months of April, May, and June, at from thirty shillings to two guineas each.

The number of horses kept in this county amounts to between thirty and forty thousand, but very few of them are bred in it. Such as are employed in agricultural operations, as well as those used by the brewers, distillers, and carmen of London, are mostly bred in Leicestershire and the adjoining counties. The coach and saddle-horses are principally brought from Yorkshire. No horses can surpass the draught horses of the brewers, coal-masters, &c. in strength and figure. Hogs are kept in considerable numbers, but chiefly by the malt-distillers, for whom they are purchased lean at a large market held on Finchley Common, to which there are vast numbers brought from Shropshire and other distant counties. The fattened hogs are bought for the hog-butcheries about London; and the bacon cured here is reckoned very little inferior to that of Wiltshire and Yorkshire. A great supply of poultry is reared in Middlesex, chiefly, however, for home consumption. Many pigeons and rabbits are also bred, particularly in the neighbourhood of London, by the poor people and journeymen tradesmen. The only regular warren in the county is that on Uxbridge Common; so that a great proportion of the rabbits sold by the poulterers in London are of the house-breed.

Middlesex, considering the proximity of every part of it to the British metropolis, cannot boast of such good roads as might be expected. For, notwithstanding the immense sums raised to keep them in repair and proper condition, it is a fact, that even the great roads which branch off immediately from the city, as from a centre, are frequently suffered to remain in the most neglected state, especially during the winter months. This arises, in a great measure, from the inappropriate means employed in cleansing them, and from the inadequacy of the materials employed in their construction and repair, to sustain the continued pressure of the immense loads which are constantly drawn along them. It must be confessed, however, that many improvements in this respect have been made within these few years, and that even as they are, they would be accounted excellent in every other part of Europe, except in the neighbourhood of London. The parish highways, as they are denominated, are usually kept in excellent order; but the same remark cannot be applied without considerable limitation to the streets of London, which, in the carriage-ways, are usually paved with Scotch granite. The canals which intersect Middlesex are the Grand Junction canal, and the Paddington canal. The former, striking off from the Thames at Old Brentford, passes the grounds at Sion Hill and Osterley, and running through a rich corn district near Hanwell, Norwood, Harlington, West-Drayton, Cowley, Uxbridge, and Harefield, leaves this county near Rickmansworth. This canal, which is navigable for vessels of sixty or seventy tons burthen, has fourteen locks to Harefield Moor, where the level is 114 feet two inches above that of the river Thames. From its numerous cuts, side branches, and collateral streams, it is, beyond doubt, the most important inland navigation in the kingdom, as it affords a direct water communication to all the various manufacturing towns of Warwickshire, Staffordshire, Lancashire, Derbyshire, and several other counties. The general breadth of this canal is thirty feet, but at the bridges it is contracted to fifteen. The Paddington canal branches off from it near Cranford, and is continued on a level from thence to the dock at Paddington, the sides of which are occupied with yards and warehouses, for the reception and security of merchandise. The advantages derived to the metropolis and the country at large from this canal, are likewise various and important. A third canal, called the Regent's Canal, stretching from the Thames, west of London, to join that river near Limehouse, has been lately projected, and is now carrying into execution. Though there are no streams of any consequence which take their rise in this county, several considerable

derable ones water it in different directions. Of these, the most important, not only in Middlesex, but in England, is the Thames, which serves as the boundary between this county and Surrey, as already mentioned. See THAMES.

The other principal rivers of Middlesex are the Colne, the Brent, and the Lea; all of which discharge their waters into the Thames. The Lea, which joins it at Bow Creek, is navigable as high as Ware and Hertford. All of these waters are covered at different points with mills, and other machinery, employed in the various departments of manufactures and the arts. Besides these streams there are several others, which, though of trivial size, have some claims to attention. Fleet Brook, which is now enclosed from the view in its passage through London, was formerly navigable for barges. It takes its rise among the high grounds at Hampstead Heath and Caen Wood, from whence it proceeds by Kentish Town, Pancras, Bagnigge Wells, Mount Pleasant, and Saffron-hill, crossing Chick-lane, and running under Fleet-market and Bridge-street, where it enters the Thames. The New River is an artificial stream, formed by the collected waters of several small springs issuing from the vicinity of Chad-well, in Hertfordshire. (See NEW RIVER.) Several mineral springs rise in the immediate vicinity of London; and some of them were formerly of much repute, though they are now but seldom used. The Spa fields, north of London, derive their name from the number of chalybeate springs that rise within them, of which that at Islington Spa, called also New Tunbridge Wells, is the principal. At Bagnigge Wells are springs both chalybeate and cathartic. The other springs of note are St. Chad's Wells, near the bottom of Gray's-inn-lane road, Kilburn Wells, Acton Wells, and several more situated at Hampstead, and in the parishes of St. Pancras and Shadwell.

Middlesex, as containing London, is the principal seat of commerce and manufactures in Great Britain. While its traders visit the most distant parts of the known world, its artificers at home produce almost every variety of articles which any district in the country can furnish. The chief portion of these, as may be presumed, is manufactured in London and its suburbs: but many important manufactories are likewise spread over the county; most of them, however, the property of individuals established in the town.

The maintenance of the poor in this county is too important a branch of its civil economy to be passed over unnoticed, even in a general account like the present. According to the returns made to parliament on this subject, in the year 1804, the number of persons maintained in workhouses, from the 20th of April 1802 to the 12th of April 1803, was 15,186; and the number of those relieved out of work-houses, 47,987. The total annual expence, incurred in supporting the former, was 224,048*l.* 2*s.* 1½*d.*; and the expence of relieving the latter, 121,901*l.* 12*s.* 3*d.*; making in all, the sum of 364,034*l.* 0*s.* 10½*d.*, or 5*l.* 15*s.* 3*d.* for each parishioner. Besides these, however, there were 32,506 persons, not parishioners, who had received occasional relief, to the amount of 3250*l.* 12*s.*: so that the whole sum expended for the benefit of the poor, during that year, was 367,284*l.* 12*s.* 10½*d.* The amount of the rates, for the same period, was 490,144*l.* 1*s.* 7¼*d.*; an average of 10*s.* 10½*d.* *per* head on the whole resident population, then computed, as has been seen, at 818,129 persons. Eight persons in the hundred, according to this calculation, were relieved by the poor's rate. Independent of these parochial burthens, there were then 1132 friendly societies, of which 54 were stated to be female societies, and 750 to have been enrolled at the quarter-sessions, pursuant to the acts passed in the 33d and 35th years of his present majesty. The total number of persons belonging to these societies is stated at 72,741, (of whom 3754 were females,) being nine in a hundred of the resident population.

The Romans seem to have had only two stations in this county: Londinum or Augusta, now London; and Sullonicæ or Brockley hills, near Elstree, on the borders of Hertfordshire. Roman remains, however, have been discovered at many other places. The Roman roads appear to have concentrated in London, and to have branched off from that city in different directions, as from a common centre. The Watling-street, running from Dover, is presumed to have entered Southwark at the point now called Dowgate, and, keeping along the present Watling-street, to have quitted the city at Aldersgate. After this, its precise direction cannot be easily determined; but it probably turned westward at the end of Old-street, and continuing along Wilderness-row and Clerkenwell, crossed the Fleet Brook, and ascended the hill at Portpool-lane; thence pursuing a north-westerly direction, it fell into the tract which now forms the high road to St. Alban's, and approaching the station of Sullonicæ, passed on through Elstree to Verulamium. The Ikenild-street, taking an easterly direction up Old-street, and over Bethnal Green, went on by Old Ford to Camalodunum or Colchester. The Ermin-street led northwards through Islington, Stoke Newington, and Hornsey, to Enfield: then turning off near that town, it passed Clay-hill, and entered Hertfordshire. A fourth Roman road led into Surrey and Berkshire, by the towns of Brentford, Hounslow, and Staines, along the course of the present turnpike; and there seems every reason to believe that a fifth took the direction of Essex, through Whitechapel and Stratford-le-Bow. Several camps of British and Roman construction are dispersed throughout the county, but none of them are peculiarly interesting: and in general it may be remarked, that, except in London and Westminster, there are few remains of antiquity in Middlesex, which have any claims to the particular notice of the antiquary.

Middlesex is divided into six hundreds, exclusive of the cities and liberties of London and Westminster, and the Tower Hamlets. The total number of parishes, places, precincts, and extra-parochial places, in the whole county, as returned under the population act, was 234. All of these, with the exception of the city and liberties of Westminster, which are governed by the dean and chapter of Westminster, are included in the diocese of London. It contains nine market-towns, distinct from the metropolis, namely, Barnet, Southall, Finchley, Uxbridge, Brentford, Hounslow, Edgeware, Staines, and Enfield. Uxbridge market is principally for corn; and at Hounslow there is always a very considerable show of fat cattle, for the supply of the London butchers. Beauties of England and Wales, vol. x. by E. W. Brayley. Camden's Britannia, by Gough, fol. vol. ii. Stukeley's Itinerary, fol. Agricultural Survey of Middlesex, by Middleton, 8vo.

MIDDLESEX, a county of America, in Massachusetts, bounded north by the state of New Hampshire, east by Essex county, south by Suffolk, and west by Worcester county. It is nearly of a square form; its greatest length being 52, and its greatest breadth 42 miles. It has 42 townships, containing 46,928 inhabitants, and was made a county in the year 1643. It is watered by five principal rivers, *viz.* Merrimack, Charles, Concord, Nashua, and Mystick, besides some smaller streams. The chief towns are Charlestown, Cambridge, and Concord. The southern and northern sides of the county are hilly, but none of the hills exceed 100 feet in height; and they are either covered with

with wood, or cultivated to the summit. The air is generally serene, and the temperature mild. The soil in some parts is rich black loam, but in others it is light and sandy. It produces the timber, grain, and fruit, which are common throughout the state, either by natural growth or cultivation.—Also, a maritime county of Connecticut, bounded north by Hartford county, south by Long Island sound, east by New London county, and west by New Haven. It is divided into six townships, containing 13,874 inhabitants, of whom 72 are slaves. The chief town is Middleton.—Also, a county of New Jersey, bounded north by Essex, north-west and west by Somerset, south-west by Burlington, south-east by Monmouth, east by Rariton bay, and part of Staten island. It contains 17,890 inhabitants. From the mouth of Rariton river to Brunswick, the land on both sides is generally good, both for pasture and tillage, and produces considerable quantities of every kind of grain, and of hay. The chief town is New Brunswick.—Also, a county of Virginia, on the south side of Rappahannock river, on Chesapeak bay, about 35 miles long, and 7 broad, containing 1687 free inhabitants, and 2516 slaves. The chief town is Urbanna.

Middlesex, one of the three counties into which the island of Jamaica is divided; the two others being Cornwall and Surry. This county is composed of eight parishes, one town, *viz.* St. Jago-de-la-Vega, or Spanish Town, the capital of the island, and thirteen villages.

Middlesex, *Bill of*, in *Law*. See Bill.

MIDDLETON, *Sir* Hugh, in *Biography*, a public-spirited man, was the sixth son of Richard Middleton, esq. governor of Denbigh castle, in the reigns of Edward VI., Mary, and Elizabeth. The subject of this memoir settled in London, as a goldsmith; but in early life he had engaged in mining speculations in his own country, and worked a copper-mine in Cardiganshire, which brought him in a considerable income. During the reigns of Elizabeth and James I., the citizens of London obtained a power to bring a new supply of water to the city, from certain streams or springs in Middlesex or Hertfordshire. Various attempts were made; but they were all abandoned, on account of the difficulty and expences attached to so vast a concern. At length the city made over to Mr. Middleton, and his heirs, all the powers and rights conferred by an act of parliament; and he began the business in the year 1608. Two springs, one rising near Ware, and the other at Amwell, in Hertfordshire, were united for the supply of an artificial river, which was conducted to the metropolis. The expences of the undertaking were so great, that they exhausted the fortune of the projector, who, having in vain applied to the corporation of London for assistance, procured it from the king, to whom a half-share of the concern was made over, in consideration of his taking an equal share in the expences. This great work was completed in 1613; and on Michaelmas day, the water was let into the reservoir of Islington with great solemnity. Mr. Middleton was rewarded with the honour of knighthood; but his profits were so small, that he was under the necessity of engaging in the business of a surveyor, or what is now denominated a civil engineer, and in that capacity rendered essential services to his country, by various schemes of mining, draining, &c. In 1622 he was created a baronet, and he died in the year 1631; since which, the value of the shares in this New River, as it is still called, have advanced so much as to create large fortunes to the heirs of the original holders. A hundred pounds share, some years since, sold as high as fifteen thousand pounds. Of late, however, there have been several acts of parliament passed in favour of other projects, which will be noticed under the article Water-*Works*, and which have reduced the value of the New River shares full one half. It is the fashion now to decry the company as extravagant in their charges for supplies of water; but it should be remembered, that the shares of this corporation, like those of other commercial companies, are perpetually changing their masters; and it is probable that the majority of share-holders, when their value was even at the highest, had paid their full price, so as to gain only a moderate interest upon their purchase money. Biog. Brit.

Middleton, William, a Welsh poet, was born at Gwernsnog in Denbighshire, and died about 1600. He served in the armies of queen Elizabeth, and afterwards commanded a ship of war; and when at sea, turned the book of Psalms into Welsh verse. This work was finished in the West Indies, in 1595. He was also the author of a Grammar, and Art of Poetry, published in 1598.

Middleton, Conyers, a celebrated divine of the church of England, was born in the year 1683 at Richmond, in Yorkshire, where his father was minister. At the grammar-school of that town he was educated, and from a very early period he gave fair promise of future excellence. At the age of seventeen he was sent to Trinity-college, Cambridge; and in 1702 was chosen a scholar upon the foundation, and took his degree of B.A. In a short time afterwards he entered into deacon's orders, and officiated as curate to one of the senior fellows of his college, at Trumpington, a village near Cambridge. In 1706 he was elected fellow of his college, and in the following year he proceeded M.A. Soon after his election to the fellowship, he took an active part in the measures which were concerting in opposition to Dr. Bentley's imperious conduct, as master of the college; and he united in a petition to the bishop of Ely, which charged the doctor with many misdemeanors. For his zeal in this business he was considered by the doctor as his most determined and dangerous enemy. While this discussion was carrying on, Mr. Middleton married a lady of large fortune, and was obliged to vacate his fellowship; but he still resided at Cambridge, till he was inducted to a living in the Isle of Ely. To this he removed, but finding the situation unhealthy, he left it in about a year, and returned to Cambridge, where he was when George I. paid a visit to the university. On this occasion he got his name inserted, with those of several others, in the royal mandate for the degree of doctor of divinity, which he accordingly received from the hands of Dr. Bentley, the regius professor. Dr. Middleton on this occasion resisted the fees, for the ceremony called creation, which led to a controversy, that run out to a considerable extent, and which was carried on with great bitterness. The addition made to the public library at Cambridge, by a present from the king of bishop More's books, which had been purchased at the expence of six thousand pounds, induced the university to pass a decree for erecting a new senate-house, that a suitable place might be provided for the reception of his majesty's donation. This decree was accompanied with a vote for a new office in the university, *viz.* that of principal librarian, which was conferred upon Dr. Middleton. Such a promotion was no more than what was justly due to his literary merit. To shew how well qualified he was for that appointment, he published, in 1723, a little piece, entitled "Bibliothecæ Cantabrigiensis ordinandæ Methodus quædam; quam Domino Procancellario Senatuique considerandam et perficiendam, Officii et Pietatis ergo proponit." Soon after the doctor had completed the arrangement in the new library, his health requiring a change of climate, he applied for leave of absence from the university; and having obtained a

special

ſpecial grace for that purpoſe, though not without difficulty, he ſet out for the continent, in company with lord Coleraine, a nobleman of conſiderable learning, who, upon their arrival at Paris, introduced him to the celebrated Montfaucon. Here Dr. Middleton ſeparated from his lordſhip, and travelled by the direct route for Rome, where he arrived early in the year 1724. After reſiding in this city about twelve months, Dr. Middleton returned through France to England, and arrived at Cambridge in the latter end of the year 1725. Almoſt immediately after his return he publiſhed a tract, entitled "De Medicorum apud Romanos veteres degentium Conditione Diſſertatio; qua contra Viros celeberrimos Jac. Sponium, et Ric. Meadium M.D.D. ſervilem atque ignobilem eam fuiſſe oſtenditur." Dr. Mead had juſt before this publiſhed an oration, in which he had defended the dignity of the medical profeſſion, and endeavoured to vindicate it from the reproach of its having been held in ſuch low eſtimation by the ancient Romans, as to be left in the hands of ſlaves and the meaneſt of the people. In defence of the opinion of the learned phyſician, a work was publiſhed under the title of "Ad Viri Reverendi Con. Middletoni, S.T.P. de Medicorum apud Veteres Romanos degentium Conditione, &c. Diſſertationem Reſponſio." This was publiſhed without any author's name, but it was ſoon found to be the production of profeſſor Ward, who had been engaged by Dr. Mead to write it; and at his expence it was printed and publiſhed. Dr. Middleton replied in a very ſpirited defence both of his character and argument, entitled "Diſſertationis de Medicorum Romæ, &c. Defenſio." With this the doctor finiſhed his part of the debate; and through the whole progreſs of it, he did not fail on every occaſion to expreſs a proper regard for Dr. Mead's real merit: and this literary altercation did not prevent them from living afterwards upon very good terms with each other. While our author was at Rome, he had the advantage of beholding popery in the full pomp and diſplay of its pageantry, which he compared rather to the ſolemn acts of idolatry of old Rome, than to any thing recommended by the plain and ſimple precepts of Chriſtianity. He examined it very accurately; and with the view of tracing the ſimilarity, he made notes and obſervations while he was in Italy; and, after his return home, kept up an epiſtolary correſpondence with his friends and acquaintance there. From theſe materials he drew up, and publiſhed in 1729, "A Letter from Rome, ſhewing an exact Conformity between Popery and Paganiſm; or, the Religion of the preſent Romans derived from that of their heathen Anceſtors." This performance was exceedingly well received by the public, and went through ſeveral editions in a very ſhort ſpace of time. While, however, the author was entitling himſelf to the thanks of the Proteſtant world, by expoſing the corruptions and impoſtures of the Romiſh church, there were ſome, even of the church of England, who took grievous offence at the book, pretending that he had attacked the Popiſh miracles with a gaiety that ſeemed to contemn all miracles, and particularly thoſe of our Saviour, by invalidating the force of certain rules which had been eſtabliſhed by ſome divines as the criterion of true miracles. Our author next made an attack upon Dr. Waterland's, "Vindication of the Scriptures, &c." which had been written in reply to Tindal's famous book, entitled "Chriſtianity as old as the Creation." This drew upon Dr. Middleton the charge of infidelity, and he narrowly and with much difficulty eſcaped academical cenſure. During the conteſt in which he had involved himſelf on this ſubject, he was appointed to the new profeſſorſhip of phyſiology at Cambridge, which had been founded in purſuance of the will of Dr. Woodward. He delivered, in the year 1731, a Latin inaugural oration, at his entrance upon the office, that did credit to the appointment of Dr. Woodward's executors. The duties of this poſt Dr. Middleton diſcharged with fidelity and reputation, till the year 1734, when he reſigned it. In the following year he publiſhed "A Diſſertation concerning the Origin of Printing in England, ſhewing that it was introduced and practiſed by William Caxton, at Weſtminſter, &c" About this time the doctor was introduced to the celebrated lord Harvey, by whoſe advice and encouragement he undertook to write "The Hiſtory of the Life of M. Tullius Cicero." This great work, which was well adapted to his taſte, and for which he was perfectly qualified, employed ſo much of his time and attention, that it was not ready for publication till the year 1741, when it appeared in two volumes, 4to. It was publiſhed by ſubſcription, and the profits enabled him to purchaſe a ſmall eſtate in the neighbourhood of Cambridge, at which he uſually ſpent the ſummer ſeaſon.

While Dr. Middleton was employed on the life of Cicero, a vacancy occurred in the maſterſhip of the Charter-houſe, and he was mentioned for it by ſir Robert Walpole, and came to London with the hope of obtaining it; but was diſappointed in his expectations, and returned to the compoſition of his favourite work. In the progreſs of this work, he engaged with Mr. Tunſtall in a controverſy reſpecting the authenticity of Cicero's letters to Brutus, and of thoſe of Brutus to Cicero. He alſo, about the ſame period, publiſhed "Germana quædam Antiquitatis eruditæ Monumenta, quibus Romanorum veterum Ritus varii tam ſacri, tam profani, tum Græcorum atque Ægyptiorum nonnulli illuſtrantur, Romæ olim maxima ex Parte collecta, ac Diſſertationibus jam ſingulis inſtructa." This work, which conſiſted of the figures of thoſe curious remains of antiquity that he had purchaſed at Rome, and other places, with a diſſertation on each, was followed, in 1747, by "A Treatiſe on the Roman Senate, in two Parts," which terminated Dr. Middleton's labours in profane literature; and he now proceeded to the publication of a treatiſe, which laid the foundation of another fierce controverſy with his clerical brethren. It was publiſhed in 1747, and was "An introductory Diſcourſe on the miraculous Powers ſuppoſed to have ſubſiſted in the Chriſtian Church from the earlieſt Ages, &c." To this numerous anſwers were written, which, however, did not prevent him from proceeding with his plan; and in 1749 he produced the larger work, to which the former was, as it aſſumed to be, only an introduction. This was entitled "A free Inquiry into the miraculous Powers, &c." The main object of the *Inquiry* is to ſhew, that there is no ſufficient reaſon to believe that any miraculous powers did ever actually ſubſiſt in any age of the church, after the times of the apoſtles. The publication of this piece raiſed up againſt him a hoſt of adverſaries, who charged him with the moſt pernicious deſigns. He had, however, the ſatisfaction of knowing that the truth of his argument was generally admitted by almoſt all enlightened and diſintereſted readers. The author ſet about preparing an "Anſwer to all the Objections made againſt the free Inquiry;" which, however, he did not live to publiſh. A few months after his death, the greater part of what he had written was given to the world, under the title of "A Vindication of the free Inquiry, &c." In the ſpring of 1750 he publiſhed "An Examination of the Lord Biſhop of London's Diſcourſes concerning the Uſe and Intent of Prophecy." The deſign of the biſhop's diſcourſes was to ſhew, that there is a manifeſt connection between the prophecies of every age, from the beginning of the world to the commencement of the gospel of Jesus Christ; which chain of prophecies, delivered at different times, and reaching through several thousand years, is yet manifestly subservient to one and the same administration of Providence. Dr. Middleton denied the principle, and laboured to refute the theory of the prelate; maintaining that the authority of the gospel, as far as it is grounded on prophecy, rests on those single and independent predictions, which are delivered occasionally in the law and the prophets, and not on any fanciful scheme of prophecy deduced from Adam and the antediluvian world. Within a few months of the publication of the last-mentioned work, our author's constitution began to give way; and on the 28th of July 1750, he departed this life. His character has been drawn with great accuracy, by the writer of his article in the General Biography, from which we shall extract a few sentences. "That Dr. Middleton was a very learned and ingenious divine, will not be disputed by any one. That he was an ardent lover of truth, as well as steady and disinterested in the pursuit of it, may be fairly concluded from the circumstances of his life above related, the sacrifices which he must have made by adopting and avowing sentiments that at once cut off all his hope of preferment, and the firmness with which he encountered the utmost rage and malice of fierce bigots and hypocritical zealots. That he was a sincere believer in the Christian religion, his own express and repeated declarations sufficiently prove, as well as his concise and admirable exposure of one of its most artful and malignant enemies, in his "Letter to Dr. Waterland," and his devoting many of his learned inquiries to its service. His faith he acknowledges was not of that kind which can easily digest incredibilities, but only a principle grounded on the perception of truth, and claiming no other merit than that of being a slave to his reason, to whose dictates it paid an absolute and unreserved submission. Confined within these just limits, however, it produced the noblest fruits, in a life spent in habits of temperance, study, and the search after truth; and which, in other respects, likewise, was as exemplary and agreeable to the rules of the gospel, as that of the most zealous of all his orthodox opponents." There were found among his papers, after his death, materials for a life of Demosthenes, correspondent to that of Cicero. In 1752, his "Miscellaneous Works" were published in four volumes, 4to. of which a second edition was published in five volumes, 8vo.

MIDDLETON, in *Geography*, an interior township, in Essex county, Massachusetts, incorporated in 1728, and containing 598 inhabitants; 20 miles N. of Boston.—Also, a city, post-town, and port of entry of Middlesex county, pleasantly situated on the western bank of Connecticut river. Its public buildings are a Congregational church, an Episcopalian church, a court-house, and naval office. It contains about 500 houses, and carries on a considerable trade.

MIDDLETON, a post-town of the county of Cork, Ireland, which was a borough before the union, and which, from its proximity to Cork harbour, has some business, chiefly carried on at the village of Ballinacurra, about a mile distant. Here are an endowed school, a barrack, two bolting mills, and a brewery. The parish, from a union made several years ago, is one of the most valuable in Ireland, being above 3000*l. per annum.* Middleton is 121 miles S.W. from Dublin, and 12 miles E. of Cork, on the road to Youghel.

MIDDLETON, a market-town and parish in the hundred of Salford, and county palatine of Lancaster, England, was first constituted a town in the year 1791, since which time it has been gradually increasing in extent and population. The market is held on Friday every week, in a very commodious market-place, laid out by lord Suffield, who is lord of the manor. The government of the police here is confided to two constables, who are chosen annually at the court-leet. In the church, a venerable pile of building, are several monuments of the Assheton family, who for many centuries were resident in this parish. The side aisles of this edifice are embattled; and in the windows appear some stained glass of shields, and other devices. A carved screen of seven compartments divides the chancel from the choir. It is ornamented with a great profusion of armorial bearings of the Asshetons, Radcliffes, Grosvenors, and Stanleys. The living is a rectory. Here is a free grammar school, which was founded by Dr. Alexander Nowel, dean of St. Paul's, and principal of Brasen-nose college, in 1572. This is now a most respectable establishment, and frequently contains between 150 and 200 scholars. Dean Nowel was educated at this place. See Charton's interesting Life of Nowel, 8vo. 1809.

The chief support of this town is derived from its cotton manufacture; but there are likewise a considerable twist manufactory, and some bleaching works. The population here, in 1801, according to the parliamentary returns of that year, amounted to 3265 persons. Beauties of England and Wales, vol. ix. by J. Britton.

MIDDLETOWN, a township of America, in Strafford county, New Hampshire; about 40 miles N. by W. of Portsmouth.—Also, a township of Rutland county, Vermont; 39 miles N. of Bennington.—Also, a township in Delaware county, New York; 40 miles W. of Catskill.—Also, a township in Newport county, Rhode island, containing 931 inhabitants. In the town, situated on the island which gives name to the state, about two miles from Newport, is a large cavity in the rocks, called "Purgatory."—Also, a town of about 60 or 70 houses in Berkley county, Virginia, near the North mountain: it has two churches, one for Presbyterians, and one for Baptists.—Also, a small post-town in Newcastle county, Delaware, on Apaquinimy creek; 21 miles S.S.W. of Wilmington.—Also, a township in Monmouth county, New Jersey, which contains two places of worship, one for Baptists, and one for the Dutch Reformed church, and 3226 inhabitants. The salt-works are in North river, which divides this town from Shrewsbury. Here is an academy of 40 or 50 students. The light-house on the point of Sandy-beach is in this township. The high lands of Navesink, which are on the sea-coast near Sandy-beach, are 600 feet above the level of the water, and are the lands first discovered by mariners in this part of the coast.—Also, a flourishing post-town in Dauphin county, Pennsylvania, on the north-west side of Swatara creek, which discharges itself into the Susquehannah, two miles below: it contains a German church, and more than 100 houses, and carries on a brisk trade with the farmers in the vicinity. It is estimated that 200,000 bushels of wheat are brought down the river annually to the landing-place, two miles from the town; 92 miles W. by N. from Philadelphia. N. lat. 40° 12′. W. long. 76° 44′. There are also two other townships of the same name in this state; one in Delaware county, and the other in that of Cumberland.—Also, a post-town in Frederick county, Maryland; nearly 8 miles W.N.W. of Frederickstown.—Also, a town in Dorchester county, Maryland; 8½ miles N.W. of Cambridge.

MIDDLEWICH, a considerable market-town in the hundred of Northwich, and county of Chester, England, is situated at the conflux of the rivers Croco and Dane, about 6 miles from Northwich, 22 from Chester, and 167 from London. Its name was derived from its centrical situation between the Wiches, or Salt Towns, of which there are three in the county; and its origin has been supposed to be as remote as the time of the Romans; the road to it from Northwich being mentioned by Camden, as raised with gravel to such a height as to be readily known for a work of that people. The church is a spacious structure, and includes two chapels. On the south side is a college, founded by Thomas Savage, archbishop of York. The government of the town is vested in a bailiff and burgesses, annually chosen. Under the population act of 1800, the number of houses was returned as 268, occupied by 1190 persons. Considerable employment is derived to the inhabitants from the manufacture of salt, which has been carried on in this town from a very early period; very valuable brine springs being found in the town and its vicinity. A cotton manufactory has been recently established here. A grammar school was founded at Middlewich about the end of the 17th century: the school-house was given by Ralph Lowndes. Markets are held on Tuesdays and Fridays, and two fairs annually. The parish of Middlewich is very extensive, and comprises 15 townships. One of these, Kinderton, has been decided by Mr. Whitaker to be the Condate of the Romans. Lysons's Magna Britannia, vol. ii. Beauties of England and Wales, vol. ii.

MIDDLING-Teeth, in the *Manege*, are the four teeth of a horse that come out at three years and a half, in the room of other four foal-teeth, seated between the nippers and the corner-teeth; from which situation they derive the title of *middling*. There is one of them above, and one below, on each side of the jaws. See Teeth.

MIDERFELS, in *Geography*, a town and castle of Bavaria; 12 miles N.E. of Straubin.

MID-FEATHER, in the English *Salt-works*, the name given to a sort of partition placed in the middle of the furnace, over which the pan is set for boiling the sea-water or brine into salt.

This partition divides the body of the furnace into two chambers. See Salt.

MID-HEAVEN, *Medium cœli*, in *Astronomy*, is that point of the ecliptic which culminates, or is in the meridian. See Culmination.

MIDHURST, in *Geography*, a market-town in the hundred of Eastbourne and county of Sussex, England, is pleasantly situated on an eminence, surrounded by several small hills, and watered by the river Arun. The petty sessions for the hundred, and a weekly market on Thursdays, are held here. In the town is a free grammar school. The church is in the patronage of lord Montague. According to the parliamentary returns of 1801, this town contained a population of 1073 persons, of whom thirty-one only were engaged in agriculture, and 194 in different departments of trade.

Adjoining to the town is a plot of ground, called the *borough* of Midhurst, which has the privilege of sending two members to parliament; though, like the borough of Old Sarum, not a single house stands within its limits. The situation of the burgage tenures, however, is distinctly marked by large stones set up for that purpose. This place possesses its privileges as a borough by prescription, having been the scite of a town of considerable importance previous to the Norman conquest. The governing officers here are a steward and bailiff, who are chosen annually at the court leet of the manor, and exercise jurisdiction over the town.

Gale and Stukeley regard Midhurst as the Miba of Ravenna, from a tortuous etymology of its name; but Camden considers the opinion of these antiquaries on this subject as wholly devoid of probability, all the MSS. being against them.

In a park, at a short distance from the town, stand the ruins of Cowdray house, which was formerly the seat of the ancient family of Montague. This noble edifice was destroyed by fire in 1793, when most of the furniture and valuable paintings which it contained were consumed. It was an immense building, of a quadrangular form, with a court in the centre, which was ornamented with a fine reservoir of water. An account of this house, with views of it, were published in the Vetusta Monumenta, by the Society of Antiquaries; but it is to be regretted that the history of the town has never been laid before the public. Our chief authority for this article is Hay's History of Chichester, 8vo. 1804, which is very unsatisfactory.

MIDIAH, a town of European Turkey, in Romania, on the Black sea; 69 miles E. of Adrianople.

MIDIAN, *Land of*, or *Midianitis*, in *Ancient Geography*, a country inhabited by the Midianites, who were the descendants of Abraham by Keturah, and who were seated on the N. of the Amalekites; having the Dead sea on the W., the Ishmaelites on the E., and the Moabites and Reubenites on the S.; the river Arnon parting them from this last tribe. Their country was hot, sandy, and in many parts of it quite desert; yet it abounded with cattle, particularly with camels, which were useful beasts of burden for their caravans, with which they traded into Egypt in the time of the patriarch Jacob. The land of Midian was divided into a kind of pentarchy, or five kingdoms, in the time of the Exodus; so that the Israelites, in the war which they waged with the Midianites, are said to have slain its five kings, whose capitals are supposed to have been situated near the Dead sea. They had also a famous metropolis, called after the name of their progenitor, often mentioned in the prophetic books of scripture, as well as by other authors; particularly by Josephus, who places a town of that appellation near the Red sea, not far from the spot where Ptolemy places that of Madiana. (See Madian.) Besides these towns, there were in this country Dibon-Gad, a large town on the river Arnon, and Almon-Diblathaim, not far from it, Beeroth, so called from its many wells, and some others, placed by geographers within the Midianitish territories. As to the city of Midian, it is probable that they rebuilt it, after the havock committed upon them by the Israelites, because Eusebius and St. Jerom, who place it on the river Arnon, eastward of the Dead sea, and south of Ar, or Areopolis, inform us, that in their time some remains of it were visible.

MIDIANITES, in *Ancient History*, derived their origin and name from Midian, the fourth son of Abraham by Keturah. He, as well as the rest of his brethren, having received a portion from their father, were sent into the East country, that they might be at a proper distance from Isaac. The Midianites, in early times, were confounded with the Ishmaelites (see that article); and many ages afterwards they are mentioned in conjunction with the Nabatæans and Kadarenes, the posterity of Nabioth and Kadar, the sons of Ishmael. We also find them so incorporated with the Moabites, that Moses seems to have regarded them as almost one nation. Their religion was the same, and they acted in the strictest concert together against him and the Israelites. They were likewise united by ties of blood with these nations, as on the one side they were descended from Abraham, and on the other from Lot; and, moreover, as they happened to live in the northern and southern parts of their country, they joined either the Moabites or the Ishmaelites. The Midianites were a very numerous race, and

and may be diftinguifhed into two claffes, *viz.* fhepherds and merchants. The fhepherds moved here and there in tents, and drove their cattle before them; even when they went to war. The merchants alfo travelled from place to place in companies or caravans, as the merchants of thofe parts do at this day, and left the care of their cattle to the women. The former had probably no fixed habitations, except fome ftrong holds near their borders; the merchants alfo had few or none but marts or ftations, in places convenient for their trade. Thefe, by exchanging their gold and jewels with their brethren for their cattle, enriched the fhepherds with precious ornaments. Their manners refpectively differed according to their mode of life; but they are in general reprefented as being very fumptuous in their apparel. (See Judg. viii. 26.) From the book of Job (ch. xix. 23, 24.) we learn, that the ufe of writing was known at an early period in thofe parts among the defcendants of Abraham; and the Midianites being of the number, we may reafonably fuppofe, could not have been unacquainted with it. They muft alfo have had fome knowledge of arithmetic, and alfo of fhip-building; fo that we may extend the circle of their fciences beyond writing and arithmetic, and allow them a competent fkill in geography, geometry, and aftronomy. The Midianites varied in religion as much as in their manner of life. In the north of Midian they appear in the days of Mofes to have been addicted to all the abominations of the Moabites; but in the fouth we find that they were attached to a rational and fublime fyftem, long after their brethren had funk into the groffeft corruption. The government of the Midianites is reprefented rather as ariftocratical than monarchical. Their chiefs, however, are ftyled kings. The moft ancient account of this nation that occurs, after what we have already ftated, is that of their war with Hadad the Horite, when Midian was fmitten by him in the field of Moab. The next is that of their purchafing Jofeph from his brethern for twenty pieces of filver, and carrying him away with them into Egypt. See the article Joseph.

Many years after this event there lived in Midian, near the Red fea, a prieft or prince of the fouthern Midianites, called Jethro; whofe daughters were molefted by fome fhepherds, and prevented from procuring water for their father's flocks. On this occafion Mofes, who in his flight from Pharaoh had arrived in Midian, interpofed on behalf of thefe females, and caufed the fhepherds to retire. In confequence of this feafonable act of kindnefs, Mofes was invited to the houfe of Jethro, who gave him one of his daughters in marriage, and kept his fon-in-law with him forty years. (See the article Moses.) When Mofes overcame Sihon the Amorite, the Midianites were at enmity with Ifrael; at leaft thofe who bordered upon the Moabites; and they feem about this time to have been very active in feducing the Ifraelites from the worfhip of God to idolatry. The Jewifh lawgiver, however, made preparation for invading their country, and they fortified their caftles and combined all their ftrength in order to refift the enemy. Their efforts were unavailing; as they were defeated with great flaughter, and all their cities and caftles were laid in afhes, and their country plundered and defolated. About 150 years after this flaughter of the Midianites, two kings, named Zebah and Zalmunna, appeared as their conductors in a war againft the Ifraelites; and they were joined by the Amalekites and Arabians. The deftruction occafioned by thefe combined forces continued for feven years; and the Ifraelites were compelled by the ravages of the plains and by want of fuftenance, to retire to the mountains, and fhelter themfelves in caves and fortreffes. Gideon, however, exerted himfelf for the refcue of his country; and his efforts were fo fuccefsful, that the Midianites never afterwards prefumed to contend with Ifrael. They were, however, a powerful nation many ages after this event, as well as famous for their induftry, riches, and the magnificence of their tents; but in the firft century of the Chriftian era their name funk into difufe, and was fwallowed up by that of the more powerful people of Arabia. Between 3 and 400 years ago there was a ruined city, which bore the ancient name, in the neighbourhood of which they pretend to fhew the place where Mofes watered his father-in-law's cattle. Abulfeda calls it Medyan, and Mofes's father-in-law, Shoaib; and the place is ftill one of the ftations in the pilgrimage from Egypt to Mecca, under the name of Shoaib's cave. Anc. Un. Hift. vol. ii.

MIDNAPOUR, in *Geography*, a river of Hindooftan, fituated partly in Bengal, and partly in Oriffa; bounded N. by Burdwan and Pachete, E. by Biffunpour and Hoogly, S. by Mohurbunge, and W. by Allahabad, about 110 miles long, and from 30 to 40 broad. The capital of the fame name is a town of Bengal; 60 miles W. of Calcutta. N. lat. 22° 28′. E. long. 87° 27′.

MIDNIGUNGE, a town of Hindooftan, in Oude; 25 miles N. of Allahabad.

MIDNOI. See Copper *Ifland.*

MIDNYPOUR, a town of Hindooftan; 35 miles N.E. of Benares.

MIDONNO, a town of Japan, in the ifland of Niphon; 85 miles N.N.W. of Jedo.

MIDRIFF, in *Anatomy*. See Diaphragm.

MIDSAMA, in *Geography*, a town of Japan, in Niphon; 12 miles N.E. of Tomu.

MIDSHIP, is a term of diftinction, applied by fhipwrights to feveral pieces of timber which lie in the broadeft part of the veffel, called the *midfhips*, although it is not in the middle of her length with regard to the breadth; it is a fuppofed line from the ftem to the ftern-poft.

Midship-*Beam*, is the beam upon which the extreme breadth of the fhip is formed, and which is fituated in the midfhip frame, nearly in the middle of her length, ferving as a ftandard from whence the dimenfions and proportion of the maft and yards are to be taken. See Beam.

Midship-*Frame*, is a name given to that timber, or combination of pieces, formed into one timber, which determines the extreme breadth of the fhip, as well as the figure and dimenfion of all the inferior timbers.

Midship-*Men*, are officers on board a fhip of war, whofe ftation, when they are on duty, is, fome on the quarter-deck, others on the poop, &c.

Their bufinefs is, to mind the braces, to look out, and to give about the word of command from the captain, and other fuperior officers. They all affift, on occafion, both in failing the fhip, and in ftowing and rummaging the hold; and in performing the neceffary bufinefs of the veffel, either aboard or afhore. The number of midfhip-men, like that of all other officers, is always in proportion to the fize of the fhip to which they belong. Thus a firft-rate man of war has twenty-four, and the inferior rates a fuitable number in proportion. No perfon can be appointed a lieutenant, without having previoufly ferved two years in the royal navy in this capacity, or in that of mate, befides having been at leaft four years in actual fervice at fea, either in merchant fhips, or in the royal navy.

MIDSUMMER-Day, is the feftival of St. John the Baptift, held on the 24th of June. See Quarter-*Day*.

MIDWAY, in *Geography*, a town, or rather a village, of America, in Liberty county, Georgia, 10 miles N.W. of Sunbury.

Sunbury. Its inhabitants are descendants of emigrants from Dorchester, near Boston, who migrated in 1700.—Also, a township of Rutland county, Vermont; E. of and adjoining Rutland.

MIDWIFE, a woman employed in assisting women in child-birth. Johnson supposes it to be derived from a Saxon word, meaning mead, or reward. As the practice of midwifery was entirely confined to women, until very lately, we have no term by which to denominate a male practitioner, but the barbarous compounded one, man-midwife. Had a more significant term been found for the women, we might have used it as we have the word author, from which we have made authoress, a female writer; though we think Johnson neither admits that word, nor the word man-midwife into his dictionary. The Romans, entertaining, perhaps, a more favourable opinion of the capacities of women, have the word autrix, a female writer, from auctor, which seems to justify us in the use of the word authoress. The French, more fortunate, call a midwife an accoucheuse, from the verb accoucher, to put to bed, and the male practitioners, accoucheurs; a term which we have now pretty generally adopted.

MIDWIFERY is the art of delivering women of their young. It must be nearly coeval, as a practice, with the creation. At first it was very simple, and consisted solely in the knowledge of the method of dividing the navel-string. Animals usually bite it asunder with their teeth. Women, probably, first made use of the sharp edge of a stone, or of a shell, for the purpose, which is the mode still practised in barbarous countries. As difficulties would occasionally occur, either in the exclusion of the fœtus, or of the placenta, or after birth, some female friend, or relative, would be called upon to give assistance. If the placenta happened to be detained beyond the usual time, which is one of the most ordinary accidents in labours, the assistant would naturally attempt to draw it away by the funis, which she would find hanging from the pudenda. If a leg or arm of the fœtus presented, instead of the head, she would, doubtless, take hold of the presenting part, and endeavour by that means to draw the child from its confinement. In these attempts, if it should be one of the lower limbs that presented, her exertions would generally be crowned with success; but as the obstacle making assistance necessary, supposes a relative disproportion between the birth and the passage through which it is to pass, the child would usually be dead born. On the other hand, if an arm presented, the same success would attend the exertions of the midwife in a few cases only; as in premature birth, or where the child happened to be remarkably small. It would more commonly happen, that all attempts to bring the child in that posture would fail; but the uterus persisting to exert itself, or, in other words, the labour-pains continuing, they would sometimes thrust down the feet, or the breech of the child, the head and shoulders gradually receding, and rising upwards, and it would at length be forced into the world in that position. In these cases, though the child would be dead, the woman would frequently recover. It would more often happen, that this evolution would not take place, and that the woman, exhausted by long continued and fruitless exertions, bruised and injured by the pressure of the fœtus, and tormented by the distention of her bladder, no egress being allowed to the urine, would fall a sacrifice to the pressure of so many accumulated evils.

Some of the earliest means made use of in tedious and difficult labours, appear to have been, anointing the pudenda with oils, and putting the woman into warm baths, as we find it recommended by Hippocrates, Avicenna, and other ancient writers; by these means they hoped to relax the parts, and render them more easy of distention, and thence to procure a freer passage for the fœtus. This continued to be the practice for many ages.

From examining the little that has been written by the ancients on the subject, it is evident they had no knowledge of that species of obstacle to the birth of the child, which is occasioned by the mal-conformation of the bones of the pelvis of the woman. They attributed the whole of the difficulty to a rigidity of the muscles, or of the ligaments connecting the bones of the pelvis together, which they hoped by these means to loosen.

Hieronymus Mercurialis, who flourished about the middle of the sixteenth century, tells us, it was not unusual to put women on a course of bathing and anointing several weeks before they attained to the period of parturition. Speaking of what is to be done, prior to the labour, he says, "Utatur balneis aquæ dulcis, in quibus herbæ laxantes et emollientes coquantur. Inungatur etiam eodem tempore, dorsum, et pecten, similiter loca muliebria iis linimentis, quæ possunt emollire, et lenire." (De Morb. Mul. lib. ii.) Another custom which was probably only practised among the common people, was placing the parturient women in an erect posture, that they might profit by the weight of the fœtus, and shaking them strongly; thinking, probably, that the child would drop down, as fruit falls from the tree.

"Alii," Moschiou says, (Harm. Gynæc. p. 11.) "ad scalas ligabant, et sic pendere jubebant; alii infinitum deambulare et salire cogebant; alii scalas ascendere; alii autem, manibus sub axillis missis, a terra sublevabant, et diutius exagitabant." Hippocrates had long before, and probably with the same view, recommended in cases where the head of the child presented, but on account of the straightness of the passage was detained above the brim of the pelvis, to anoint the parts, and to put the woman into a bath of warm water. These methods failing, the head of the child was to be opened with a scalpel, and then to be extracted with a strong iron pincers, or hooks. "Caput gladiolo dissectum. Instrumento quod constringat comminuto, et ossicula per ossium volsella extrahito, aut unco attractorio ad claviculam uti firmiter adhæreat immisso, non confestim, sed paulatius remittendo, et rursus adurgendo, extrahito." (Hip. Oper. Om. Fœsio. p. 618.) Celsus recommends a similar practice, (lib. vii. cap. 29. De Medicina.) Avicenna mentions a kind of fillet that was used in these cases. (See the article **Fillet.**) This contrivance, although it had a few favourers, was never in general use; the more common method in tedious and difficult births was to diminish the bulk of the child, or of the part nearest to the external surface, with scalpels, or other cutting instruments, and then to draw it away with iron hooks, pincers, or forceps, armed with teeth. Those who wish to see the forms of these instruments, or a more particular account of the methods of applying or using them, may consult Albucasis's Methodus Medendi, lib. ii. and Ruett, De Conceptione et Gen. Hominis, in which many of them are particularly delineated and described.

As cases of such difficulty as to render the use of instruments necessary are rare, not occurring oftener than once in five or six hundred labours, and as the practice of midwifery was for many ages, indeed so late as to the end of the sixteenth century, almost exclusively in the hands of women, it is not to be wondered at, that little improvement was made in the method of assisting women in the only cases that would come under the care of the surgeon, until a very late period. Hippocrates having learned that in ordinary births the child presented with its head to the orifice of the womb, thought that in all cases, when it offered in a different posture,

posture, it ought to be pushed back, in order to bring down the head. This he attempted to do even when the breech or the feet came first. If an olive, he says, comes into the neck of a bottle across, and you attempt to bring it through in that posture, you will either crush the olive, or break the glass; but as it is of little consequence which of the ends of the olive comes first, he should have seen, that it is nearly equally immaterial which end of the child comes first. This, however, does not seem to have occurred to him, and as his name was of great authority in every thing relating to medicine, his rules continued to be followed until the middle of the sixteenth century. Ambrose Parey, who flourished about that time, first recommended turning the child and bringing it by the feet in all cross presentations. This may be considered as the first material improvement that had been made in the practice of midwifery. The rule was further explained and extended by his pupil Guillemeau, and afterwards by Mauriceau, Le Motte, Peu, Puzos, and other French writers, and it has long since been adopted by the practitioners in the art in every part of Europe, not only in cross-births, but in all cases of flooding, in whatever posture the child may present, also when the funis umbilicaris comes down before the head of the child, and by some surgeons, as we shall see by and by, in cases where the forceps or lever are now ordinarily used.

A few years before Ambrose Parey's book appeared, Eucharius Rhodion, a physician of Frankfort, published the first popular work that we are acquainted with on the subject. As it was intended for the instruction of the midwives, it was printed at first in the German language. In 1532, it was translated into Latin, under the title of "De partu hominis," and in a few years after, into French, English, and other modern languages. The practical rules recommended by him, are such as he had learned from Hippocrates, Avicenna, and other ancient writers. In cross presentations, the midwife was to endeavour to bring down the head; when this could not be effected, if the breech, or feet, were next the uterine orifice, the child was to be allowed to come into the world in that posture, taking, however, especial care, he says, that the hands should be brought down, and placed one on each side of the body of the child, a rule which could not possibly be followed, and which shews that the writer had never practised the art. The same censure may be passed upon almost every regulation, that had been hitherto promulgated on the subject. Nearly all of them tending rather to mislead, than to inform the practitioner, and to increase rather than diminish the pain, difficulty, and danger of the labour.

We have two translations of Rhodion's book into our language. The first by Richard Jones, who dedicated it to Katherine, queen to king Henry VIII. It was printed in the year 1540, and is decorated or illustrated with some indifferent engravings on copper, which, however, are esteemed, as being the first specimens of the kind executed in this country. In 1545, Thomas Raynold, physician, published a second translation. This has passed through several editions, under the title of "The Birth of Mankind," and was nearly the only manual used by the midwives until the year 1672, when Dr. Hugh Chamberlen gave a translation of Mauriceau's "Treatise on the Art of Midwifery," in which the first dawning of a rational practice of the art appears. In the preface to the translation, Dr. Chamberlen announces an invention, "known only," he says, "to his father, brothers, and himself, with which they were enabled to terminate the most difficult labours, without injuring either the mothers or the children." Though he gives no intimation by which it could be discovered what were the means used for the purpose, yet it was in time found out to be the forceps. The merit of the invention consisted in making the blades of the instrument separable, and capable of being locked, or united together, after being introduced into the vagina, and placed one on each side of the head of the child. (See the article FORCEPS, in *Midwifery.*) A most invaluable discovery, and which has deservedly immortalized the inventor. (See CHAMBERLEN, HUGH.) But he at first very much overrated their power, imagining that they were applicable in all cases, where the head of the child was "enclavée," or fixed in the pelvis, not having met with a case, we may suppose, where the bones forming that cavity were considerably distorted. Accordingly he undertook to deliver a woman whose pelvis was so contracted and narrow, as to render it impossible that the head of a full grown fœtus should pass through it undiminished. The operation, or trial, which was performed at Paris, where he went with the view of selling his secret, failed. Mortified at the check he received, he left the country, and went to Amsterdam, where he is said to have sold the secret to Roonhuysen, a surgeon in great practice in that city, who has the credit of having invented the lever which bears his name. See that article.

About the same time Deventer, an eminent surgeon of a town in Holland of that name, acquired considerable fame by his practice in the obstetric art. As the form, as well as the manner of using the forceps and lever were kept secret by the proprietors of those inventions, or only disclosed to persons who would pay a large sum of money for them, Deventer declaimed violently against the use of instruments, affirming he could terminate the most difficult labours with his hand alone. He contended that the greatest obstacle to the birth of the child arose from the oblique position of the uterus, its fundus falling too much forward, or to one side of the abdomen of the mother. The head of the child was therefore forced by the pains, ether against the sacrum, or against one of the sides of the pelvis, instead of being directed into the centre of that cavity. In all cases of difficulty, if the head of the child was not forced down so low as to render it impracticable, he passed his hand into the uterus, turned the child, and delivered it by its feet. When that could not be done, he introduced his left hand into the back part of the vagina, and gradually pushed back the bones of the coccyx, so as to give space sufficient for the head of the child to pass. In cases where the pelvis was distorted, he must necessarily have failed in his attempt, for the same reason that Chamberlen failed with his forceps, but as such cases would only occur once in five or six hundred labours, that small number of exceptions would give little check to his fame, which was continued to his name for many years after his death. This doctrine and practice, which have long since been exploded, were patronized in this country by Mowbray, sir Richard Manningham, and Eaton, who were all averse to the use of instruments.

The construction and use of the forceps being at length made public by Mr. Butter in the third volume of the Medical Essays in 1732, and more fully by Chapman in 1734, and that of the lever by M. Preville, in his translation of Smellie's Midwifery into French, published at Paris, in 1754, the teachers of the art were careful in instructing their pupils in the method of employing those instruments, which have entirely superseded the rude practice of Deventer. The *perforator* and *crotchet* (see those articles) came into use about this time, and continue to be employed in the few cases that require such assistance, in the place of the scalpel, and the forceps with teeth.

Practitioners in the art being now possessed of such powerful

erful affiftants, it was to be feared they might be induced to have recourfe to them for the purpofe of accelerating the labour, in cafes where there were only fuch obftacles as in a moderate fpace of time would be overcome by the pains. Cautions againft this fafcinating practice are found in all the late treatifes on the art. Smellie, who had a larger fhare of practice, and who inftructed a greater number of pupils than any other profeffor in his time, is frequent in his admonitions againft ufing art, other than in aid of nature, where fhe is abfolutely and decidedly incompetent to the completion of the labour. How feldom alfo this happens, he is careful to inform them. He very much fimplified the form of the forceps, and that they might not be ufed before the head of the child had defcended fufficiently low in the pelvis, he confiderably reduced them in length; he alfo contrived a method of locking them, much more convenient than had been before ufed. Before he retired from the practice, in which he introduced feveral valuable improvements, he publifhed, in 1752, "A Treatife on the Theory and Practice of Midwifery," which contained the fubftance of every thing that was ufeful, that had been printed on the fubject, as well as the refult of his own extenfive practice. This was followed by a fet of plates, in large folio, correctly drawn and well engraved, illuftrating his practice. Soon after he publifhed two volumes of cafes, arranged in claffes, referring to his treatife, and fhewing the efficacy of the rules he had there inculcated.

While Smellie was making large ftrides toward improving every part of the practice of midwifery, and bringing it to perfection, Levret, and various other writers on the continent, were exerting themfelves in a fimilar manner, and with perhaps equal felicity. In the mean while, hofpitals and other inftitutions were formed, for the reception of parturient women. As the management and care of thefe were under the immediate direction of the phyficians and furgeons, and the opportunity which for fo many ages had been wanting, of acquiring an exact knowledge of the procefs of a natural labour, and of the obftacles that occafionally obftructed its progrefs and completion, was now obtained. To this alfo, the change that had been taking place, within fomething more than a century, in the opinions and manners of the public had contributed. Several phyficians and furgeons had, in the courfe of that time, applied themfelves to the practice of midwifery. Hence we find, Mauriceau, Deventer, Ruyfch, Roonhuyfen, our countryman Dr. Chamberlen, and others, enjoying a confiderable portion of practice in the art.

The cuftom of employing men in the place of women, originated among the ladies of the higheft rank in France, and gradually defcended to the middling and lower claffes of the people. The advantages derived from the change, both in the manner of conducting the labour, and in the management of the woman and child after the labour, became fo obvious, that the practice has by degrees fpread over all Europe. That the poor who could not, and a few who from prejudice ftill refufed to employ men, might reap the benefit of the improvements that have been made in the practice of the art, no women are now allowed to engage in the bufinefs, who have not been previoufly inftructed by fome public teacher, and who do not obtain from him certificates of their qualifications. The confequence of thefe arrangements has been, that every part of the art has been inveftigated with the greateft care, and fuch has been the zeal of the profeffors, or perfons engaged in the practice, that the works on the fubject of midwifery, which have been publifhed within lefs than a century, are fufficiently numerous to form of themfelves no inconfiderable library. Thus this art, which was fo late in being cultivated, has already attained a degree of perfection, that puts it on an equality, at leaft, with any other branch of medicine. Of this great mafs of publications, many of them excellent, it may be fufficient to mention, among foreign productions, Puzo's "Traitè des Accouchmens," Baudelocque's "Art des Accouches," Crant's "De Re Inftrumentaria," and the "Opufcula" of Roederer, and of Plenk, which embrace the whole circle of the art. Among our own writers, White "On the Management of Pregnant and Lying-in Women," and Rigby "On Uterine Hemorrhage," have each in their way given directions that are calculated to abide the teft of time. "Obfervations on human and comparative Parturition," publifhed in 1794, may be added, as containing a number of curious and ufeful facts not generally known or attended to. The late Dr. William Hunter's fplendid plates of the human gravid uterus, and not more fplendid than correct, places before our eyes the fœtus at different periods of its exiftence, fhews the pofture in which it lies in the uterus, and the manner in which it is connected with that vifcus; and laftly, Dr. Denman's "Introduction to the Practice of Midwifery," which has already paffed through feveral editions. For comprehenfivenefs and exactnefs, it holds the fame rank now that Smellie's Treatife did at the time when it was publifhed, embracing and explaining, in a luminous and judicious manner, every thing, we believe, that is known on the fubject.

MIEDNIKI, in *Geography*. See MEDNIKI.

MIEDZIAL, a town of Lithuania, in the palatinate of Wilna; 52 miles S. of Breflaw.

MIEDZINECZE, a town of Poland, in the palatinate of Brzefk; 25 miles W. of Brzefk.

MIEDZIRZECZKA, a town of Poland, in the palatinate of Volhynia; 52 miles N.N.W. of Zytomiers.

MIEDZYRZECZ, a town of Lithuania, in the palatinate of Novogrodek; 44 miles W.S.W. of Novogrodek.

MIEDZYRZYCZ, a town of Ruffian Poland, in the palatinate of Kiev; 32 miles W.S.W. of Czyrkafy.

MIEGIA, in *Botany*, appears to have been named by Schreber in honour of two Swifs anatomifts and botanifts, who flourifhed in the beginning and middle of the laft century. Moft probably they were father and fon, but we are not fufficiently acquainted with their hiftory pofitively to affert this. John Rodolph Mieg publifhed his inaugural Differtation on *Chamæmelum leucanthemum* at Bafil, in 1721, which was reprinted two years afterwards. Achilles Mieg publifhed a work in 1751, at the fame place, which he calls *Specimen obfervationum anatomicarum atque botanicarum*, and in this are defcribed fome rare graffes, as well as the genus *Montia*. Schreb. 786. Willd. Sp. Pl. v. 1. 311. Mart. Mill. Dict. v. 3. (Remirea; Aubl. Guian. 44. Juff. 34. Lamarck Illuftr. t. 37.)—Clafs and order, *Triandria Monogynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume fingle-flowered, of two, ovate, concave, ribbed valves; the upper fhorter and obtufe; the lower fomewhat longer and rather acute. *Cor.* of two, fwelling, ribbed valves; the outer ovate, obtufe, within the lower calyx-valve, and longer than it; the inner oblong, compreffed at the top, rather acute, with folded margins, longer than the outer, within the upper calyx-valve. Nectary of one leaf, ovate, gibbous at the back, flightly compreffed, acute, fmooth, thick, corky, thinner at the tip and margins, fhorter than the corolla, oppofite to its inner valve, enclofing the germen. *Stam.* Filaments three, capillary, longer than the corolla; anthers oblong, acute. (Aubl.) *Pift.* Germen oblong, nearly triangular, within the nectary; ftyle fimple, capillary, longer than the corolla; ftigmas two, capillary. *Peric.* none. *Seed* folitary, oblong, triangular, approaching

approaching to globose, wrapped up in the nectary, and inclosed by the permanent calyx and corolla.

Eff. Ch. Calyx of two opposite valves, single-flowered. Corolla of two valves. Nectary of one leaf, enveloping the germen.

Obs. The above generic character was made by Schreber, from the parts of fructification as they were found by him in a dried specimen. The nectary he observes is remarkable. Aublet's character of *Remirea* is very different from that of Schreber's *Miegia*.

1. M. *maritima*. Willd. n. 1. (Remirea maritima; Aubl. Guian. t. 16.)—A native of the sea shores of Cayenne and Guiana, flowering and bearing seed at various times of the year.—*Root* perennial, creeping, long, branched, knobbed, solid. *Stems* about six inches high, branched at their summits, leafy and scaly below. *Leaves* oblong, narrow, rigid, striated, acute, rough at the margin, sheathing at the base. *Flowers* crowded together into a nearly sessile, terminal, short and thick panicle. The *roots*, when bruised or masticated, afford a grateful, aromatic smell, shewing an affinity to the genus *Cyperus*, from which indeed this plant seems to differ chiefly in its solitary florets, and corky nectary.

MJEIBOW, in *Geography*, a town of Lithuania, in the palatinate of Novogrodek; 58 miles W.S.W. of Novogrodek.

MIEKOW, a town of Austrian Poland, in the palatinate of Cracow; said to have been built after the model of Jerusalem by Gripsius Jaxa, after his return from a pilgrimage to that city; 12 miles N. of Cracow.

MIEL, Jan, in *Biography*, a painter, known in Italy by the name of Giovanni della Vite, probably because he chose to disregard the grand style of art in which at first he practised with Andrea Sacchi, and paint common nature and living objects.

He was born in Flanders in 1599, and first learnt to paint under Gerard Segers; but he soon left him, and went to Italy, where he studied the antique and the works of the best masters with great success, and was employed to paint pictures as large as the life for several of the churches in Rome. He had the honour to study in the academy of Andrea Sacchi, then in great repute, and was invited by him to assist in a large picture he was then engaged upon; but they soon disagreed, and Miel left his master in disgust, piqued with a satiric expression of Sacchi concerning his talent for painting *bambocciate*, or scenes of merriment, drolls, &c. his imagination principally leading to such subjects.

In consequence, he set himself afresh and with increased diligence to study the grand style, and rival Sacchi; but after a time gave it up almost altogether, and painted those subjects for which nature appears to have designed him, with a portion of talent nearly equal to Bamboccio himself. His success was fully equal to his skill, and he filled the cabinets of the nobility of Rome, Florence, and other places, with his ingenious performances.

The lustre of his fame induced Charles Emanuel, duke of Savoy, to invite him to Turin, where he arrived in 1659, and was received by his highness with great respect, and engaged to paint for him several pictures relative to the chase, in which he introduced an immense number of small figures of persons of all ranks, horses, dogs, different species of game, &c. all which he finished so much to the satisfaction of the duke, that he honoured Miel with knighthood, and besides paying him handsomely for his pictures, presented him with a cross ornamented with diamonds of great value.

He remained at Turin six years, during which time he painted a great number of pictures, and at the end of it died of a slow fever, or rather consumption, brought on, Baldinucci asserts, by his uneasiness at not obtaining his patron's permission to revisit Rome.

MIELAN, in *Geography*, a town of France, in the department of the Gers, and chief place of a canton, in the district of Mirande; 6 miles S.S.W. of Mirande. The place contains 1403, and the canton 10,221 inhabitants, on a territory of 272½ kiliometres, in 29 communes. N. lat. 43° 25'. E. long. 0° 23'.

MIELEC, a town of Poland, in the palatinate of Sandomirz; 56 miles S.W. of Sandomirz.

MIELNICK, a town of Poland, in the palatinate of Bielsk; 44 miles S.W. of Bielsk.

MIEN, a town of China, of the second rank, in Setchuen; 56 miles W. of Pao-king. N. lat. 51° 28'. E. long. 104° 29'.

MIEN-TAM-KEOU-TOUKA, a town of Chinese Tartary. N. lat. 41° 1'. E. long. 119° 42'.

MIEN-YANG, a town of China, of the second rank, in Hou-quang. N. lat. 30° 12'. E. long. 112° 49'.

MIER-CHAS-KUN, a town of Persia, in the province of Farsistan, containing about 400 houses and several bazars, the ruins of Persepolis; 40 miles N. of Schiras.

MIERIS, Francis, in *Biography*, a most admirable painter of the Flemish school, who was born at Leyden in 1635. He acquired the principles of the art under Gerard Dow, who honoured him with the title of prince of his disciples, and this praise he justly merited, for he more nearly approached the purity and delicacy of Dow than any other man has ever done: indeed, in some respects he became viceroy over that king of high and minute finishing, being more agreeable in his designs, and having more correctness in drawing.

He painted portraits with great delicacy, but his general subjects were conversations, persons performing on musical instruments, doctors with their patients, and such like: these he treated with great ingenuity in composition and execution; painting his draperies with so much minuteness, that all the peculiarities of their different textures are visible. Silk, velvet, stuff, carpets, &c. all were not only marked with their general characteristic appearances, but the threads of their texture were made as visible as in nature, and rendered completely deceptive. It is this attention to minutia, united to breadth and truth, which give so much value to his works; which are very rare, and very costly of course. His own valuation of his time was a ducat an hour: and for one picture of a lady fainting, with a physician attending her, and applying remedies, he was paid at that ratio, so large a sum as fifteen hundred florins. The grand duke of Tuscany is said to have offered 3000 for it, but was refused. One of the most beautiful of the works of Francis Mieris, in this country, where they are not very common, is in the possession of Mr. P. H. Hope, and is known by the appellation of the "Shrimp Man." He died in 1681, and is called by connoisseurs the Old Mieris, to distinguish him from his son,

Mieris, William, who of course is called the Young. He was born at the same place as his father, and learned from him the art of painting, till he arrived at the age of 19; when, his father dying, he was left to follow the dictates of his own mind, which happily led him to study nature, and in that study he made a considerable progress towards obtaining an equal reputation with his father.

At first he painted the same subjects as his father, but afterwards, ambitious of a nobler fame, he attempted higher subjects, but not being prepared with proper studies, he did not succeed so happily as his adventurous spirit deserved. He sometimes painted landscapes and animals, and also modelled his figures with very considerable skill. Probably this

this divifion of his time and ftudies operated to prevent his arriving at the fame degree of excellence in minute finifhing as his father: certain it is, that his works will not bear the comparifon, being poor and thin, and wrought by a lefs full, and more timid pencil. He died in 1747, aged 85, and left a fon, Francis Mieris, born at Leyden in 1689, who not having the talent of originality, employed himfelf in copying the works of his father and grandfather; and it is moft likely, that nine out of ten of the works diftributed at fales under the name of Mieris, are the fecond-hand productions of this, the younger Francis.

MIES, or MIZA, in *Geography*, a town of Bohemia, in the circle of Pilfen; 14 miles W. of Pilfen. N. lat. 49° 43'. E. long. 13° 6'.

MIETOU, a town of Sweden, in the government of Abo; 14 miles N.W. of Abo,

MIEZA, a town of Spain, in the province of Leon; 42 miles W. of Salamanca.

MIFFLIN, a county of Pennfylvania, in America, furrounded by Lycoming, Franklin, Cumberland, Northumberland, Dauphin, and Huntingdon counties; containing 1851 fquare miles, 1,184,960 acres, and divided into eight townfhips. The mountains of this county abound with iron ore, and feveral forges have been erected for working it. It is well watered by the Juniatta and other ftreams; it has feveral mineral fprings, and abundance of lime-ftone. This county and Center contain 13,609 people. The chief town is Lewiftown.—Alfo, a fmall town in the above county, on the E. fide of the Juniatta; 12 miles E. of Lewiftown.—Alfo, a fort on a fmall ifland, at the mouth of Schuylkill river; about fix miles S. of Philadelphia.

MIFFLINBURG, a poft-town of Northumberland county, Pennfylvania; 218 miles from Wafhington.

MIGLERE, LA, a town of Italy, in the department of the Po, on the Stura; 24 miles N.N.W. of Turin.

MIGLIAJO, in *Commerce*, a weight and meafure by which oil is fold at Venice: the weight = 40 miri, each being 25lb.: the meafure = 1210lb., or 40 miri, each = $30\frac{1}{4}$lb.: fo that fuch a miri correfponds to about $4\frac{1}{4}$ Englifh gallons.

MIGLIANICA, in *Geography*, a town of Naples, in Abruzzo Citra; 7 miles E. of Civita di Chieti.

MIGLIANO, a town of Naples, in Principato Ultra; 15 miles N.N.E. of Conza.—Alfo, a town of Italy, in the department of the Lower Po; 15 miles E. of Ferrara.

MIGLIAVACCA, GIOVANNI AMBROSIO, in *Biography*, counfellor of legation, and opera poet to the elector of Saxony, king of Poland, author of an opera intitled "Solimano," and of many cantatas performed at Vienna and Drefden. This poet endeavoured to imitate the elegant and natural ftyle of the amiable Metaftafio.

MIGLIONICO, in *Geography*, a town of Naples, in Bafilicata; 9 miles S.W. of Matera.

MIGNANO, a town of Naples, in Lavora; 11 miles N. of Sezza.

MIGNARD, PETER, in *Biography*, an hiftorical and portrait painter, born at Troyes, in Champagne, in 1610. He was the difciple of Vouet, but quitted his fchool at an early period of his life, and went to Rome, anxious to fee and ftudy the works of Raphael, Michael Angelo, and the Caracci. He there lived with Du Frefnoy, and they ftudied together the noble works of art which that city prefented to them; they alfo travelled together to Florence and Venice, that they might leave no fource of improvement unfought which the extraordinary talents of their great predeceffors had prepared and left for their ftudy and imitation.

The refidence of Mignard at Rome, which he prolonged for 22 years, and the ftyle he acquired of compofition and drawing by the imitation of the Roman mafters, together, obtained for him the appellation of the Roman; but to judge candidly, one would imagine that the former was the principal caufe of that denomination; for his ftyle of defign favours too much of the flutter of the French fchool, inftead of the chafte fimplicity of Raphael and the beft of the Romans.

Mignard enjoyed a full fhare of favour and fortune during his life. He painted portraits of the popes Urban VIII. and Alexander VII., together with thofe of many of the nobility of Rome.

Louis XIV., hearing of his fame and abilities, fent for him to Paris, and is faid to have fat to him for his portrait ten times. Almoft all the illuftrious nobles of the French court followed the example of their fovereign, and were painted by Mignard. His ftyle of execution in thefe portraits is wrought up with all the falfe tafte and pompous parade which diftinguifhed that vicious period of the French nation; when parade paffed current for true fplendour; what was only fpecious or fubtle, was received as ufeful and learned; and bombaft affumed the ftation due only to true dignified fimplicity. His pictures are all flutter; every thing feems in motion; even when the fcene is laid in a clofe room, the draperies are flying about as in a high wind. The actions of his figures are in affumed airs, like pompous, and not unfrequently bad actors, and the colouring of his pictures, though frefh and vigorous, is not true, but teinted, and reminds the obferver of the pallette. With thefe defective points in his character as an artift, Mignard is not unworthy of regard. His drawing is correct: his arrangement of parts is ingenious: and his invention fertile. He contrived to make his pictures ornamental, and is the beft portrait painter of the French fchool.

His patron, Louis, ennobled him; and, after Le Brun's death, appointed him his principal painter, and the director of the manufactories of Seve and the Gobelins. He lived to the age of 85, dying in 1695. He had an elder brother, whofe name was Nicholas, a fkilful painter, but who never rofe to equality with him.

MIGNATRICE, LA, *Ital.*, a miniature paintrefs in 1770, the late Mrs. Corri, whofe family name was Bicchelli, then a young and beautiful woman, a profeffed miniature paintrefs, and a brilliant and very pleafing finger at the Academie, or private concert of the nobility and gentry at Rome, where no females are allowed to appear on the ftage, was beft known by the title of La Mignatrice. After her marriage with her finging-mafter, Corri, fhe came with him to Edinburgh in 1772, to fing at the concerts in that city, where he was engaged to direct the concerts, and give inftructions in mufic. They remained at Edinburgh till about the year 1787, when they removed to London, where Mrs. Corri, mother of the accomplifhed Mad. Duffec, died in 1802, much lamented by her family, friends, and all who had heard her fing in the early part of her life.

MIGNONETTE, in *Botany*. See RESEDA.

MIGNOT, STEPHEN, in *Biography*, a learned French ecclefiaftic, a native of Paris, was born in the year 1698. He was brought up to the church, and was admitted to the degree of doctor by the faculty of the Sorbonne, and rendered himfelf eminent for his acquaintance with the facred fcriptures, the fathers, ecclefiaftical hiftory, and canon law. When upwards of fixty years of age, he was elected a member of the Royal Academy of Infcriptions and Belles Lettres. He died in the year 1771, leaving behind him numerous works, of which the following feem moft worthy of notice: *viz.* "A Treatife on Commercial Loans," in four volumes; "The Rights of the State and of the Prince, with Reference to the Eftates of the Clergy," in fix volumes; "The

"The History of the Contest between Henry II., and St. Thomas of Canterbury;" "The Reception of the Council of Trent, in Catholic Countries;" "A Paraphrase on the New Testament," in four volumes; "A Memoir relating to the Liberties of the Gallican Church."

MIGRATION, or TRANSMIGRATION, the passage or removal of any thing out of one state or place into another; particularly of colonies of people, birds, &c. into other countries.

The migration of the souls of men into other animals after death, is the great doctrine of the Pythagoreans, called the *metempsychosis*.

The migration of birds, as the swallow, quail, stork, crane, field-fare, woodcock, nightingale, and other birds of passage, is a very curious article in natural history, and furnishes a notable instance of the powerful instinct impressed by the Creator. Dr. Derham observes two things remarkable in this subject; the first, that these untaught, unthinking creatures, should know the proper times for their passage, when to come, and when to go; as also, that some should come when others go? No doubt, the temperature of the air, as to cold and heat, and their natural propensity to breed their young, are the great incentives to those creatures to change their habitation. But why should they at all change their habitations? and why is not some certain place to be found, in all the terraqueous globe, affording them convenient food and habitation all the year round?

The second, that they should know what way to steer their course, and whither to go. What instinct is it that moves a poor foolish bird to venture over vast tracts of land and sea? If it be said, that, by their high ascents up into the air, they can see across the seas; yet what should teach or persuade them, that another land is more proper for the purpose than this? that Britain, for instance, should afford them better accommodation than Egypt? than the Canaries? than Spain? or any other of the intermediate countries? Physico-Theol. p. 349.

Lud. de Beaufort remarks, that birds, in their migration, observe a wonderful order and polity: they fly in troops, and steer their course through vast unknown regions, without the compass. (Cosmol. Divin.) It is to be added, that the birds of passage are all peculiarly accommodated, by the structure of their parts, for long flights.

Naturalists are divided as to the places whither birds of passage retire when they leave us. Mr. Willughby thinks the swallows fly into Egypt and Ethiopia.

Olaus Magnus says, they lurk in holes, or under water; which is confirmed by Etmuller, who assures us, that he saw a bushel of them taken out of a frozen fish-pond, all hanging together, head to head, feet to feet, &c. in one cluster. (Dissert. ii. c. 10.) Olaus adds, that this is a common thing in the northern countries; and that such a cluster being carried accidentally by some boys into a stove, the swallows, after thawing, began to fly about, but weakly, and only for a little time.

A farther confirmation of this account was given by Dr. Colas, a person very curious in such things, to the Royal Society. Speaking of the way of fishing in the northern parts, by breaking holes, and drawing their nets under the ice, he related, that he saw sixteen swallows so drawn out of the lake of Samrodt, and about thirty out of the king's great pond at Rosineilen; and that at Schlebitten, near a house of the earl of Dohna, he saw two swallows just come out of the waters that could scarcely stand, being very wet and weak, with their wings hanging on the ground. He added, that he had often observed the swallows to be weak, for some days after their first appearance.

Some of our own countrymen have given credit to the submersion of swallows; and Klein patronises this doctrine in his Hist. Av. 205, 206. But they assign no reason, why these birds are capable of enduring so long a submersion without being suffocated, or without decaying in an element so unnatural to them; when we know that the otter, the cormorant, and the grebes soon perish if caught under ice, or entangled in nets; and it is well known, that these animals will continue much longer under water than any others to whom nature hath denied that particular structure of heart, necessary for a long residence beneath that element? Mr. John Hunter, having dissected many swallows, found nothing in them different from other birds as to the organs of respiration; whereas all those animals which he had dissected, of the class that sleep during winter, such as lizards, frogs, &c. had a very different conformation in those organs. He farther adds his opinion, that these animals breathe in their torpid state; and, as far as his experience reaches, he knows they do; and he, therefore, esteems it a very wild opinion, that terrestrial animals can remain any long time under water without drowning.

There is another more probable opinion, with respect to the disappearance of swallows, which has high antiquity to support it. Aristotle and Pliny assert, that these birds do not remove very far from their summer habitation, but winter in the hollows of rocks, and during that time lose their feathers. We have had many instances of some species of swallows having been discovered in a torpid state, on the cliffs of the Rhine, in old dry walls and sand-hills in Scotland, in the chalky cliffs of Sussex, in hollow trees, and lead mines, &c. These several places are supposed to be the lurking habitations of later hatches, or of those young birds that are incapable of distant migrations; where they generally continue insensible and rigid, though, like flies, they may sometimes be re-animated by an unseasonable hot day in the midst of winter. From these facts, it is reasonable to conclude, that, though one part of the swallow tribe migrates, others may have their winter-quarters nearer home. If it should be asked, why swallows alone are found in a torpid state, and not the many other species of soft-billed birds, which likewise disappear about the same time? the following reason, says Mr. Pennant, may be assigned. No birds are so much on the wing as swallows; none fly with so much rapidity and swiftness; none are obliged to such sudden and various evolutions in their flight; none are at such pains to take their prey: and none exert their voice more incessantly; whence they suffer a great expence of strength and spirits, and acquire such a texture of blood, as other animals do not experience; and become thus disposed to a more lasting repose than other birds. But notwithstanding this concession, it is most probable that swallows in general, as well as other birds, migrate from colder into warmer climates, in search of proper food, a sure asylum from man during the time of courtship, incubation, and nutrition, and a temperature of air suiting their constitutions.

The generality of birds that remain the winter with us have strong bills, or are enabled to feed on what they can find at that season; those which leave us have usually very slender bills, and their food is the insects of the fly kind; which disappearing towards the approach of winter, compel them to seek them in regions where they may be found; and the length of the wings of the generality of these birds, enables them to prey flying, if there be food for them

them in their way, and to continue a long time on the wing without reft.

The various conjectures about the places to which they retire, are owing to want of ocular teftimony; but if we confider the vaft tracts of land yet unknown to us, we cannot doubt but there may be many places for them, in which we can have had no opportunities of finding them. But the moft probable conjecture feems, that the places to which they retire lie probably in the fame latitude in the fouthern hemifphere, as the places from whence they depart; where, the feafons reverting, they may enjoy the like agreeable temperature of the air. And, if thefe places are fuppofed to be divided from them by too large feas, why may not fome other parts of the fouthern hemifphere, which are lefs diftant, ferve their turn?

This, certainly, feems much more reafonable than that they fhould remain on our fide of the northern tropic, within a few degrees of which, at the winter folftice, it is fo cold as frequently to produce fnow; which, by difperfing fuch infects as birds that feed upon the wing fubfift on, muft make them perifh, were they not to remove to thofe warmer climates where they may ftill find food. The fwallows, as they cannot fubfift fo long in cold feafons as fome other birds of paffage, which feed, after the difappearance of flies in the air, on what infects they find in their receffes, vifit us later, and depart from us fooner, than the reft. The nightingales, and fome other birds, which leave us for the winter, are feen, fometimes, a month after the fwallows; and from the whole it feems natural to infer, that the fwallows pafs the tropic of Cancer, though it is not yet known to what place they at length retire.

The manner of the birds of paffage journeying to their fouthern abode may vary, according to the different ftructure of their bodies, and their power of fupporting themfelves in the air. Thofe birds with fhort wings, fuch as the redftart, blackcap, &c. though they are incapable of fuch long flights as the fwallow, or of flying with fo much celerity, yet may pafs to lefs diftant places, and by flower movements. Swallows and cuckoos may perform their paffage in a very fhort time; but there is for them no neceffity for fpeed, fince every day's paffage affords them an increafe of warmth, and a continuance of food.

Providence, which has guided the defencelefs animals in many other inftances to the fafeft methods of performing their neceffary works, may have inftructed many of thefe birds which have fhorter paffages to make, or places to ftop at by the way, to fly only in the night, that they may be fecure from the birds of prey; and Mr. Catefby gives a proof that fome fpecies do fo, from his own obfervation; for, lying on the deck of a floop on the north fide of Cuba, himfelf and the whole company heard fucceffively, for three nights, flights of rice birds, which are eafily diftinguifhed from all other birds by their notes, and which were paffing over their heads northerly; which is their direct way from Cuba, and the fouthern continent of America, from whence they get to Carolina, annually, about the time that rice begins to ripen, and from whence they return fouthward again, when it is gathered, and they are become fat.

That this is the cafe alfo with fome fpecies of fwallows, has been proved beyond contradiction by M. Adanfon, Hift. de Senegal, p. 67. We often obferve them collected in innumerable flocks on churches, on rocks, and on trees, previous to their departure hence; and Mr. Collinfon proves their return here, perhaps, in equal numbers, by two curious relations of undoubted credit; the one communicated to him by Mr. Wright, mafter of a fhip, and the other by the late fir Charles Wager; who both defcribed to the fame purpofe what happened to each of them in their voyages. "Returning home," fays fir Charles, "in the fpring of the year, as I came into foundings in our channel, a great flock of fwallows came and fettled upon my rigging: every rope was covered; they hung on one another like a fwarm of bees; the decks and carving were filled with them. They feemed almoft famifhed and fpent, and were only feathers and bones; but being recruited with a night's reft, took their flight in the morning." This apparent fatigue proves that they muft have had a long journey, confidering the amazing fwiftnefs of thefe birds; fo that in all probability they had croffed the Atlantic ocean, and were returning from the fhores of Senegal, or other parts of Africa.

The fhort-winged birds are fuppofed little qualified for long flights, particularly the quail, which is a bird never feen long together on the wing, or making any long flights; its not doing this frequently is, however, no proof that it is not able to do it; nor does the ftructure of its body at all befpeak its inability; and Bellonius affirms, that he faw them in great flights paffing over, and repaffing, the Mediterranean fea, at the very feafons when they leave us, and they return again. The fame inftinct that directs thefe birds to depart to diftant countries, doubtlefs alfo directs them to the fhorteft way, and fends them to the narroweft cuts, not the wider feas, to crofs.

Among the birds of paffage, we have fome alfo which come to us in the autumn, at the time when the fummer birds are leaving us; and go from us again in the fpring at the times when thefe return: thefe, however, are only four kinds; the field-fare, the redwing, the woodcock, and the fnipe; and of thefe the two laft often continue with us through the fummer, and breed; fo that the two firft feem the only kinds that certainly leave us at the approach of fpring, retiring to more northern parts of the continent, where they live the fummer, and breed; and, at the return of winter, are driven foutherly from thofe frigid climes, in fearch of food, which there the ice and fnow muft deprive them of. There are many others alfo, particularly of the duck, or wading kind, that breed and make their fummer abode in the defolate fenny parts of our ifland; and when the feverity of our winters deprives them of their food, neceffity forces them to retire towards the fea in numerous flights; where they find water unfrozen, and where they remain till the return of fummer; but thofe cannot properly be called birds of paffage.

It feems pretty evident from the whole, that the fummer birds of paffage leave us only in fearch of a more warm climate, and a greater plenty of food; both which advantages they procure to themfelves by their alternate change of climate; but the migration of the winter birds of paffage is not fo eafily accounted for, fince there is no fuch apparent neceffity for their leaving us, either on the fcore of food or climate. The place of the fummer retirement of thefe birds is Sweden, and fome other countries in that latitude; but as they would find thofe places too cold and deftitute of provifion, were they to haften immediately to them on their departure from us, they journey along gradually, and prolong their paffage through the more moderate countries of Germany and Poland; by which means they do not arrive at their northern habitations, where they are to pafs their fummer, and where they breed, till the feverity of the cold is fo far abated as to render it pleafing to them, and there is proper food for them; and when they revifit us the following

following winter, their journey is performed in the same leisurely manner.

Sweden and the other countries whence they come to us, seem the proper home of these birds; since there they were bred; and the journey they take to us being only for a warmer climate, and plenty of food, it is no wonder that, when these benefits are to be expected again in their native place, they return to it.

The principal food of these birds, while with us, is the fruit of the white-thorn, or haws, which hang on our hedges in winter in prodigious plenty; but where they breed, and seem to live most at ease, as in Sweden, &c. there are no haws, nor, indeed, in many of the countries through which they journey in their way; so that it is evident they change their food in their passage. And upon the whole it appears, that Providence has created birds, &c. with constitutions and inclinations adapted to their different degrees of heat and cold; which, to them, are most agreeable, and to which they will travel from places which to other animals might seem more agreeable: by this means no part of the globe is without its inhabitants. Phil. Trans. vol. xliv. p. 435, &c. vol. li. p. 459, &c. Pennant's British Zoology, vol. i. p. 406, &c. vol. ii. p. 709, &c.

MIGREEVO, in *Geography*, a town of Russia, in the government of Novgorod; 36 miles S. of Tcherepovetz.

MIGU, a town of Arabia, in the province of Oman; 140 miles S.W. of Julfar.

MIGUEL-ESTEVAN, a town of Spain, in New Castile; 40 miles S. of Huete.

MIGUEL-*Turria*, a town of Spain, in New Castile; 4 miles S.E. of Civdad Real.

MIGUEL, *St.*, a town of Mexico, in the province of Guatimala; 50 miles E. of Cuzcatlan.—Also, a town of S. America, in the kingdom of Grenada; 85 miles E. of Santa Fé de Bogota.—Also, a town of Spain, in the province of Seville, between the rivers Guadiana and Odier, near the coast of the Atlantic.—Also, a town of S. America, in Popayan; 90 miles E.S.E. of Pasto.—Also, a town of Paraguay; 360 miles E. of Assumption.—Also, a town of Mexico, in the province of Nicaragua, on the N.W. coast of Amapalla bay; 100 miles S.E. of Leon. N. lat. 13° 35'. W. long. 88° 56'.—Also, a town of Mexico, in the province of Mechoacan; 80 miles N. of Mechoacan. N. lat. 21° 20'. W. long. 102° 26'.—Also, a town of S. America, in the province of Chiquitos.—Also, a town of S. America, in the province of Quito; 50 miles S.W. of Quito.—Also, a town of S. America, in the audience of Quito; 15 miles N.W. of St. Josef de Huales.—Also, a mission of Spanish monks in New Albion, near the coast of the Pacific ocean. N. lat. 31° 58'. E. long. 243° 42'.—Also, a small island in the N. Pacific ocean, called also "St. Bernardo," the most westerly of the range which forms the western boundary of the canal of St. Barbara. N. lat. 34°. E. long. 240° 3'.—Also, a river of Brasil, which runs into the Atlantic, S. lat. 10° 8'.—Also, a town of Brasil, in the government of St. Paul; 15 miles E. of St. Paul.—Also, a town of Congo, and capital of the province of Ovando; 150 miles S.S.E. of St. Salvador. S. lat. 7° 45'.—Also, a town of Mexico, in the province of Culiacan, on the Ciguatlan; 30 miles S.E. of Culiacan. N. lat. 24° 6'. W. long. 107° 52'.—Also, a town of New Mexico, in the province of Cinaloa; 70 miles W.N.W. of Cinaloa.—Also, a town of New Mexico; 60 miles S. of Santa Fé.

MIGUEL, *St.* See MADEIRA.

MIGUEL *Archangel, St.*, an island in the Pacific ocean, discovered by Quiros in the year 1606.

MIGUEL *d'Ibarra, St.*, a town of South America, and capital of a jurisdiction of the same name, in the audience of Quito, containing about 10,000 inhabitants. The houses are built of stone, and tiled. The suburbs are inhabited by Indians, in mean cottages. The parish church is a large, elegant, and well-ornamented building. Here are convents of Franciscans, Dominicans, and Fathers of Mercy, a college, and a nunnery of the order of the Conception; 45 miles N.N.E. of Quito. N. lat. 0° 25'. W. long. 77° 40'.—Also, a jurisdiction of S. America, in the government of New Grenada, and audience of Quito. The temperature of the air is different in all the villages of this jurisdiction, but generally warm, on account of their low situations. Most of the farms have plantations of sugar-canes, and mills for extracting the juice, of which they make large quantities of white sugar. Some farms are planted with fruits, common in a hot climate, and in others they only cultivate cotton, which is obtained in the greatest perfection. In those farms that are situated in a less hot part of this jurisdiction are sown maize, wheat, and barley. Here are also large multitudes of goats, but not many sheep. The Indians weave a considerable quantity of cloth and cotton. This jurisdiction has several mines of salt, which supply the countries that lie to the north of it. Near a village, called Mira, there is a great number of wild asses.

MIGUEL *de Piura, St.* See PIURA.

MIGUEL *de Ribera, St.*, a town of Peru, in the diocese of Arequipa; 62 miles W.S.W. of Arequipa.

MIGUEL *de Tucuman, St.*, a town of S. America, in the province of Tucuman; the see of a bishop, containing several monasteries. Its situation is elevated and agreeable, and in its vicinity are fertile fields, and several silver mines: some mules are bred; but the chief traffic is in a kind of cars, or covered waggons, which pass to Buenos Ayres and Jujuy, and which the inhabitants are enabled to build by their abundance of wood; 200 miles E. of Copiapo. S. lat. 27° 25'. W. long. 66° 30'.

MIGUEL *Bay, St.*, a bay on the E. coast of the island of Luçon. N. lat. 14° 12'. E. long. 123° 40'.

MIHALY, a town of Hungary; 10 miles N. of Zutmar.

MIHAU, a small island in the English Channel, near the coast of France; 15 miles W. from the island of Bas. N. lat. 48° 47'. W. long. 3° 30'.

MIHEL, a district of the archduchy of Austria, between the Danube and Bohemia.

MIHIEL, ST., a town of France, in the department of the Meuse, and chief place of a canton, in the district of Commercy, situated on the Meuse, in a valley surrounded with mountains. It has six gates and three fauxbourgs. The place contains 5022, and the canton 14,010 inhabitants, on a territory of 255 kiliometres, in 28 communes. N. lat. 48° 54'. E. long. 5° 37'.

MIHIRA, a name, in the Sanscrit, for the sun. See SURYA.

MIHLACK, in *Geography*, a town of Austria; 18 miles S.W. of Freystadt.

MIJARISIMA, one of the small Japanese islands. N. lat. 34° 10'. E. long. 139° 45'.

MIJAS, a town of Spain, in the province of Grenada; 10 miles N.E. of Marbella.

MIJASKA, a river of Russia, which runs into the Iser, in the government of Tobolsk.

MIJAVARA, a town of Japan, in the island of Niphon; 12 miles S. of Awasi.—Also, a town of Japan, in the island of Ximo; 28 miles S.E. of Ikua.

MIJO, a town of Peru, in the diocese of La Plata; 70 miles E.S.E. of Lipes.

MIIT Demsis, a town of Egypt, on the east branch of the Nile; 35 miles N. of Cairo.

Miit *Gera*, a town of Egypt, on the east branch of the Nile; 12 miles S. of Mansora.

Miit *Harun*, a town of Egypt, on the east branch of the Nile; 2 miles N.W. of Miit Demsis.

Miit *el Koli*, a town of Egypt, on the east branch of the Nile; 10 miles N.N.E. of Mensora.

Miit *Lassi*, a town of Egypt, on the east branch of the Nile, opposite to Miit Demsis.

Miit *Naser*, a town of Egypt, on the east branch of the Nile; 3 miles S. of Semennud.

Miit *Kamer*, or *Miet Ghamer*, called by Savary *Mit Khamr*, a town of Egypt, on the east branch of the Nile; 24 miles N. of Cairo. This town, though small, is populous and commercial. The market places are narrow, and badly lighted; the streets are crooked and dirty. Here is a mosque, with a square tower, which seems to have served as a church for the Christians, before the Arabian conquest. Through all Egypt there is not a similar minaret; all being round, narrow, and lofty.

MIKALIDI, or Maarlich, a town of Asiatic Turkey, in the province of Natolia, situated on a river, the ancient Rhyndus, which runs into the sea of Marmora. It has a port about two miles from the town, whence they send silk, wool, grain, and fruit to Smyrna, Constantinople, &c.; 35 miles W. of Bursa. N. lat. 40° 10'. E. long. 28° 22'

MIKANIA, in *Botany*, a genus separated by Willdenow from the Cacalia and Eupatorium of Linnæus; see those articles; and named by him in honour of professor Joseph Mikan of Prague, of whose botanical performances we find nothing mentioned, except a mere catalogue of plants, an epitome of the 13th edition of the Linnæan *Systema Vegetabilium*, with some new species of Jacquin superadded, published at Prague in 1776; an octavo of 403 pages.—Willd. Sp. Pl. v. 3. 1742.—Class and order, *Syngenesia Polygamia-æqualis*. Nat. Ord. *Compositæ discoideæ*, Linn. *Corymbiferæ*, Juss.

Gen. Ch. *Common Calyx* oblong, simple, of from four to six erect, equal, oblong, channelled, unarmed, permanent scales. *Cor.* compound, uniform, discoid; florets mostly equal in number to the scales of the calyx, all uniform, perfect, fertile, monopetalous, funnel-shaped, with a regular, four or five-cleft, spreading border. *Stam.* Filaments five, capillary, short; anthers united into a cylindrical tube. *Pist.* Germen minute; style thread-shaped, mostly rather longer than the corolla, deeply divided; stigmas slender, spreading. *Peric.* none, except the permanent, somewhat expanded calyx. *Seeds* solitary to each floret, oblong, angular; down sessile, simple, longer than the calyx. *Receptacle* small, naked.

Ess. Ch. Receptacle naked. Calyx of from four to six equal leaves, containing as many florets. Seed-down simple, sessile.

Section 1. *Stem climbing.*

1. M. *Houstonis*. Willd. n. 1. (Eupatorium Houstonis; Linn. Sp. Pl. 1172. Swartz. Obs. 300.)—Stem twining. Leaves ovate, entire. Flowers spiked.—Native of bushy places at Vera Cruz. *Houston.* In Jamaica, but rare. *Swartz.* The *stem* is twining, shrubby, round, smooth, with widely spreading branches. *Leaves* opposite, stalked, ovate, pointed, entire, ribbed, shining. *Spikes* opposite, spreading almost horizontally, many-flowered. *Flowers* minute, white, inodorous. *Calyx* of four scales. *Florets* four.

2. M. *hastata*. Willd. n. 2. (Eupatorium hastatum; Linn. Sp. Pl. 1172. Swartz. Obs. 299. Kleinia? scandens; Browne Jam. 316. t. 34. f. 3.)—Stem twining. Leaves hastate, somewhat heart-shaped, acute, slightly toothed, smooth. Flowers spiked.—Native of thickets on the hills of Jamaica. *Stem* shrubby, climbing, round, striated, purplish, slightly downy. *Leaves* opposite, hastate, acutely pointed at each lobe, from one to near three inches long, three-ribbed, smooth, except a slight downiness on the ribs or veins; heart-shaped at the base; obscurely toothed or serrated at the margin. *Footstalks* about as long as the leaves, sometimes much shorter, slender. *Spikes* axillary and terminal, about the ends of the branches, downy, bracteated, near two inches long, obscurely whorled. *Flowers* usually four in a whorl, white, smelling like *Cacalia suaveolens*. The whole plant has a bitter taste. *Sw.*

3. M. *scandens*. Willd. n. 3. (Eupatorium scandens; Linn. Sp. Pl. 1171. Jacq. Ic. Rar. v. 1. t. 169. Conyza scandens, solani folio angulofo; Plum. Ic. 86. t. 99?)—Stem twining. Leaves heart-shaped, taper-pointed, wavy and toothed; lobes spreading. *Flowers* corymbose.—Native of Virginia, in a watery soil. This was introduced into the English gardens about 100 years ago, and is a hardy perennial, flowering in August and September, but of no remarkable beauty. The *stem* is rather herbaceous than shrubby, climbing, smooth, or downy. *Leaves* on long stalks, one and a half inch long, roughish, veiny, three-ribbed at the base. *Flowers* white, in axillary, stalked, leafy, more or less compound corymbs. *Seed-down* tawny; not white, as mentioned by Willdenow. *Florets* four.

4. M. *volubilis*. Willd. n. 4. (Eupatorium volubile; Valh. Symb. v. 3. 93. E. cordatum; Burm. Ind. 176. t. 58. f. 2.)—Stem twining. Leaves heart-shaped, crenate, acute, lobes rounded, approximated. Corymbs panicled.—Native of the East Indies. The *stem* in our's is very nearly smooth, much less downy than in the last. Willdenow mentions the reverse. *Leaves* much larger, exactly heart-shaped, acute, nearly smooth, bluntly crenate; occasionally entire, as figured by Burmann. *Corymbs* compound, on long stalks. *Seed-down* blush-coloured, or purplish.

5. M. *denticulata*. Willd. n. 5. (Eupatorium denticulatum; Vahl. Symb. v. 3. 93.)—"Stem climbing, angular. Leaves heart-shaped, bluntish, finely toothed, rough. Flowers corymbose."—Native of Surinam. "*Branches* with five prominent angles. *Leaves* two inches long, stalked; paler and slightly downy beneath; sometimes entire. *Florets* and *calyx-scales* four. *Seed-down* purplish." Of this we have seen neither specimen nor figure.

6. M. *tomentosa*. Willd. n. 6. (Eupatorium tomentosum; Lamarck Dict. v. 4. 410.)—Stem twining. Leaves alternate, heart-shaped, finely toothed, somewhat angulated, cottony beneath; the upper ones ovate. Spikes panicled.—Native of the Isle de Bourbon. One of Commerson's specimens was given by Thouin to Linnæus. It is said to have the scent of lilac. The *stem* is very long, slender, twining, round, cottony when young. *Leaves* alternate, stalked; smooth, or slightly cottony, above; clothed with snow-white dense pubescence, like a white poplar, beneath. *Spikes* of flowers numerous, alternate, composing axillary leafy panicles. *Calyx* smooth. *Seed-down* white.

7. M. *amara*. Willd. n. 7. (Eupatorium amarum; Vahl. Symb. v. 3. 93. E. parviflorum; Aubl. Guian. v. 2. 797. t. 315.)—Stem twining, roughish. Leaves ovate, entire; rough beneath. Flowers corymbose. Bracteas spatulate, at the base of the smooth calyx.—Native of the banks of rivers in Guiana, flowering in August. Communicated by E. Rudge, Esq. The *stems* are ten feet long, branched, twining, round, rough with short, dense, rigid pubescence. *Leaves* opposite, stalked, three inches long; nearly smooth above; rough and harsh beneath. *Flowers* in

in corymbose, leafy, axillary panicles, three together sessile at the end of each partial stalk, with two or three short, spatulate, stalked, leafy *bracteas*. *Florets* and *calyx-scales* four. When wounded, the *stem* and *branches* discharge a yellowish, viscid, aromatic fluid.

8. M. *latifolia*.—Stem twining, smooth. Leaves ovate, taper-pointed, nearly entire, smooth. Flowers corymbose. Bracteas lanceolate, at the base of the roughish calyx.—Native of the island of St. Lucia. Very near the last, but differing in the above characters. The *leaves* are dark green above, and very smooth; pale, scarcely roughish to the touch, beneath. *Inflorescence* as in *M. amara*, but the *bracteas* are much smaller, sessile, lanceolate or elliptical, minutely roughish. *Calyx* also roughish. *Florets*, and rufous *down of the seed*, half as long again as the calyx; whereas in the last species they are much shorter, and concealed within it.

9. M. *chenopodifolia*. Willd. n. 8.—"Stem twining. Leaves ovate, somewhat triangular, pointed, wavy, five-ribbed, smooth. Flowers corymbose."—Native of Sierra Leone. *Stem* with smooth striated branches, apparently climbing. *Leaves* opposite, stalked, triangular-ovate, slightly hastate, smooth on both sides. *Corymbs* dense, stalked, terminal. *Calyx* smooth, of four scales, with as many florets. *Down* reddish. *Willd.*

10. M. *auriculata*. Willd. n. 9. (Eupatorium auriculatum; Lamarck Dict. v. 2. 411. E. scandens; Thunb. Prodr. 142?)—Stem twining, angular, smooth. Leaves alternate, triangular, somewhat hastate, toothed, smooth. Stipulas rounded. Flowers corymbose.—Gathered by Sonnerat at the Cape of Good Hope; and Willdenow well conjectures that it is probably the *E. scandens* of Thunberg, with whose short definition it seems to agree. The *stem* has many angles, and is much branched, twining and zigzag. *Leaves* small, with a pair of clasping *stipulas* at the base of their stalk, and sometimes a pair of similar auricles. *Calyx* of five or six scales, with as many florets. *Lamarck.*

11. M. *stipulacea*. Willd. n. 10. (Eupatorium stipulaceum; Vahl. Symb. v. 3. 94.)—Stem twining, round, smooth. Leaves opposite, hastate, acute, somewhat toothed, smooth. Stipulas oblong. Flowers corymbose.—Gathered by Commerson in Brasil. *Stem* twining, slender, finely striated. *Leaves* stalked, much like those of some hastate *Chenopodium*; rather glaucous, and obscurely downy, beneath. *Stipulas* recurved, small, oblong, acute. *Flowers* in many axillary, opposite, stalked, often compound corymbs. *Calyx* roughish at the base, membranous upward, of four scales, with as many florets. *Down* purplish, rough, projecting, with the florets, much beyond the calyx.

12. M. *rubiginosa*. (Cacaliæ cordifoliæ varietas, foliis integris; Linn. Suppl. 352.)—Stem twining, downy. Leaves opposite, heart-shaped, pointed, wavy, finely downy. Panicles axillary, cymose. Bracteas spatulate. Native of South America? Of this we have seen but an imperfect specimen in the Linnæan herbarium, on which there is no mark to indicate its native country. By its resemblance to many of the foregoing species only, can we judge of its being a climber; for we have but an inch and a half of the *stem*, with a pair of opposite stalked *leaves*, each two inches long, with an axillary stalked corymbose *panicle*, accompanied by a pair of small leaves, to each. Every part is clothed with extremely short, dense, soft, rusty, velvet-like pubescence. The surface of the *leaves*, on both sides, sparkles with excessively minute golden resinous dots. *Flowers* not very numerous. *Bracteas* as long as the calyx, spatulate or obovate, obtuse, with or without a small point, and tapering at their base. *Scales* of the calyx very much like them in shape and size, and both are equally downy externally. *Seed-down* reddish, scarcely extending beyond the calyx. This is certainly very distinct from the following, with which the younger Linnæus, who found the specimen here described in his father's herbarium, marked *Eupatorium*, confounded it.

13. M. *cordifolia*. Willd. n. 11. (Cacalia cordifolia; Linn. Suppl. 351.)—Stem twining? angular, roughish. Leaves opposite, heart-shaped, pointed, toothed, rough. Panicles axillary? cymose, leafy. Bracteas ovate, pointed, shorter than the calyx.—Gathered by Mutis in New Spain, South America. By its near agreement with the last species, we judge this also to be a climbing plant. The Linnæan specimen consists of only a large compound corymbose *branch* of flowers, accompanied by small opposite leaves, as usual in this section of the genus, but whether it may have been axillary or terminal, we cannot determine. With it are two separate *leaves*, not unlike those of a *Helianthus*, each three inches long, of a very broad heart-shaped figure, oblique or unequal, minutely but distantly toothed, with a short taper point. They are rough on both sides, with minute harsh pale bristles, their ribs, which are three in the middle, and two at each side, clothed with rusty down. *Footstalks* two inches long, or more, rusty. *Panicle* many-flowered, with roughish angular stalks. *Bracteas* scattered, stalked, gradually smaller upwards, ovate, pointed, entire, bristly at the edges; those which are close to the flowers sessile, shorter than the calyx. *Scales* of the calyx four, elliptic-lanceolate, acute, ribbed, concave; the two outermost roughish, especially upward; the innermost only being smooth as described in the *Supplementum*. *Seed-down* reddish, rough, longer than the calyx, as are also the *florets*.

14. M. *laurifolia*. Willd. n. 12. (Cacalia laurifolia; Linn. Suppl. 351.)—Stem twining? Leaves opposite, elliptic-ovate, triple-ribbed, very smooth and shining. Panicles dense, terminal, downy.—Native of Mexico. *Mutis.* This has all the appearance of a climbing *shrub*, though Willdenow could have no reason, from the Linnæan description, to suspect it. The *branches* are much twisted, forked, round, smooth, leafy at their extremities. *Leaves* one and a half or two inches long, near an inch wide, almost elliptical, obtuse, entire, slightly revolute, rigid, smooth; varnished as it were on the upper side; thickly dotted beneath; their lateral ribs springing from the middle one at a good distance from the base, besides a pair at the very bottom. *Panicle* three inches long, dense obtuse, with hairy corymbose stalks. *Bracteas* small, oblong. *Scales* of the calyx four, linear, hairy, (by no means smooth as in the *Suppl.*), rather dilated and feathery at the tips. *Seeds* furrowed, angular, rough, nearly as long as the calyx. *Florets* and *down* much longer. *Styles* greatly protruding, with long, narrow, purplish stigmas.

Section 2. *Stem erect.*

15. M. *melissæfolia*. Willd. n. 13. (Eupatorium melissæfolium; Lamarck. Dict. v. 2. 411.)—Stem erect. Leaves opposite, ovate, crenate, sessile, downy beneath. Flowers corymbose, terminal.—Gathered by Dombey in Peru. *Stem* about two feet high, round, slightly downy, panicled above. *Leaves* sessile, and even somewhat embracing the stem, oval, coarsely crenate, green, about two inches or more in length, and one inch and a half wide. *Flowers* purplish. *Calyx* of five straight scales. *Florets* five. *Down* rough.

16. M. *satureifolia*. Willd. n. 14. (Eupatorium satureiæfolium; Lamarck Dict. v. 2. 411.)—Stem erect, branched. Leaves opposite or scattered, linear, obtuse, entire,

entire, downy. Flowers corymbose.—Gathered by Commerson at Monte Video. The *stem* seems scarcely shrubby, round, alternately branched, downy, leafy. *Leaves* mostly scattered, the lower ones only being often opposite, sessile, linear, or linear-lanceolate, obtuse, nearly or quite entire, tapering at the base, thickly dotted, minutely hairy; paler beneath. *Flowers* large, purple, a few together in tufts on terminal, corymbose, downy stalks. *Calyx* downy, but half the length of the florets and rough brownish *seed-down*. *Corolla* five-cleft, slightly hairy.

Commerson gathered at the same place a slender variety, with much smaller *leaves*, and only one or two *flowers* at the top of a few of the branches. We agree with him that, though very different in appearance, the specimen displays no distinctive specific character. Indeed we have an intermediate variety, which leaves the matter without any uncertainty. We make no apology for correcting the barbarous construction of the specific names of this and the foregoing. S.

MIKELSBURG, in *Geography*, a fortressed town of Transylvania, with a depôt of arms for the principality; 6 miles S.E. of Hermanstadt.

MIKLOS, St., a town of Transylvania; 12 miles N.N.W. of Medies.

MIKLOSVAR, a town of Transylvania, on the river Alaut; 16 miles N. of Cronstadt.

MIKOLAIOW, a town of Austrian Poland, in Galicia; 28 miles S.S.W. of Lemberg.—Also, a town of Poland, in Volhynia; 24 miles W. of Lucko.

MIKULINOZE, a town of Poland, in Podolia; 56 miles N.N.W. of Kaminiec.

MILA, a town of Thibet; 222 miles S.W. of Latac.—Also, a town of Tunis; 30 miles S. of Constantina.

MILAGRO, a town of Spain, in the province of Aragon, at the confluence of the Arga and Aragon; 5 miles E. of Calahorra.

MILAN, *Duchy of*, a country of Italy, bounded on the north by the Grisons, on the east by the Venetian states, on the south by the states of Piedmont and Parma, and on the west by Piedmont and Savoy. Its greatest breadth from north to south is upwards of 100 miles, and its greatest length from east to west 108 miles. This fertile duchy is said to contain, on 2432 square miles, a population of 1,116,850 persons; and it has formerly produced to the king of Spain a revenue of above two millions of dollars. According to Mr. Young's statement, the soil is chiefly strong loam, or loamy sand; and the climate has a singular circumstance belonging to it, that the northern mountainous tracts are mild and warm, but the plains are cold. Orange and lemon trees flourish in the open air, on the western sides of the lake of Como, though bounded by the high Alps, which to the north are covered with perpetual snow; while, in the plain of Lombardy, even to the Apennines, these trees require shelter. The Boromean isles also, in the Lago Maggiore, are covered with these delicate trees. The lands in this duchy are mostly enclosed; but its agriculture can never prosper, while the present system continues, which is that of the landlord's paying taxes and repairs, and the tenant's providing cattle, implements, and seed, and then their dividing the produce between them. For the irrigation of the country, they have canals, subsisting as early as the 11th century, some of which are more than 30 miles long, and nearly 52 feet wide. The arable lands produce the usual kinds of grain and fruits, and the pastures are excellent, affording means for breeding cattle in abundance, and for making cheese that has been every where held in estimation. The wine is good, and the mulberry trees, for the culture of silk, are numerous. Its sheep are but few and bad. Its mines have not been much explored: however, there are are some of copper and lead above the lake of Como, and the mountains; and the Boromean isles present flesh-coloured granite, and lapis ollaris is plentiful near Como. In this duchy are manufactures of wool and silk, though its silk is not equal to that of Piedmont; and it has numerous workmen in gold, silver, embroidery, and steel, as well as in crystal, agate, aventurine, and other stones. The trade of the Milanese is considerable; but its imports generally exceed its exports. Its stuffs are mostly consumed at home; its silks, stockings, gloves, and handkerchiefs, are exported.

After the fall of the kingdom of Lombardy, Milan became subject to the emperors of the West. After the contests between the emperors and the popes, it lost its form of a republic, and became subject to the archbishop: in 1277, Otto Visconti, the archbishop, was declared lord of Milan. His family long possessed this rich principality. After two or three changes it was seized, in 1535, by Charles V., as a fief of the empire, and he gave it to his son Philip; whose successors, as kings of Spain, retained the Milanese till the year 1706, when it became an appanage of Austria, though a considerable part of it had been transferred to the house of Sardinia. Its revenues have been lately estimated at about 300,000*l.* When the Cisalpine republic was formed, the Milanese was divided into four departments, *viz.* Olona, Verbano, Lario, and Delle Montagna. Milan was appointed the capital of the whole republic; and the same establishment still respects the kingdom of Italy.

Milan, a city, and capital of the lately established kingdom of Italy, and, before the revolution in France, the capital of the duchy above described. Including its gardens, it is said to be ten miles in circumference, and it is chiefly defended by a wall and rampart, together with a citadel having six bastions at some distance, so that it has been reputed a strong place. It has some straight and broad streets, among many that are narrow and crooked; but its paper windows, or those of glass and paper intermixed, give it a mean appearance. It has 12 gates, 230 churches, 90 convents, 100 religious fraternities, 120 schools, and about 120,000 inhabitants. It is the see of an archbishop, and its nobles are numerous. Its cathedral is a large but irregular building, constructed of marble, and ornamented with marble statues: its treasury, among other valuable articles, contains an invaluable coffin of rock-crystal, in which are deposited the remains of St. Charles Boromeo, cardinal and archbishop of Milan. The chief church for antiquities is that of St. Ambrose; and the Ambrosian college, in the centre of the town, was founded by Frederic Boromeo, and has sixteen professors, who communicate their instructions gratis. The fine library which he began was finished by cardinal Gelbert Boromeo, and is said to contain more than 40,000 printed volumes, and some thousands of MSS. In this college are also an academy of painting, and a museum. The seminary for sciences, where students are both taught and maintained, and the college of the nobles, are stately buildings, but inferior to the Helvetian college, founded for a number of Swiss. Here is also a mathematical academy. The great hospital is a fine building, and liberally endowed by duke Francis Sforza IV.; and its income is said to be between 90 and 100,000 rix-dollars. This hospital, which has several others dependent upon it, admits not only sick persons, but also foundlings and lunatics. The large lazaretto is only used in time of contagion. Among the civil buildings is the old and spacious regency-house, and the new and stately town-house, where is an equestrian statue of Philip II.

This city was founded by the Gauls about 584 years B.C.; but has undergone many sieges, and particularly that by the emperor Frederic I. in 1162, who, after a siege of seven months, destroyed the gates, ramparts, and edifices, leaving only a few churches, and sowed salt on the ruins. However, it recovered from these disasters; and it still maintains many manufacturers and artisans; and by means of several rivers and canals, carries on a considerable trade. In 1800 it was taken by Bonaparte; and when the Cisalpine republic was established, it became the capital of the department of Olona and of the whole republic, and it maintains the same rank in the kingdom of Italy; 132 miles W. of Venice, 65 N. of Genoa. N. lat. 45° 26′. E. long. 9° 11′.

MILAPOUR, a town of Hindoostan, in Mysore; 22 miles E. of Colar.

MILASA, or MARMARA, a town of Asiatic Turkey, in Natolia; anciently called Mylassa. In this place are the remains of three temples, and of a column, called Meander's pillar; 16 miles S.W. of Mogla. N. lat. 37°. E. long. 27° 50′.

MILATIA, a town of Poland, in Volhynia; 44 miles S.W. of Lucko.

MILAVERAM, a town of Hindoostan, in the circar of Condapilly; 14 miles N. of Condapilly.

MILAY, a town of Bohemia, in the circle of Leitmeritz; 16 miles S. of Leitmeritz.

MILAZZO, CAPE, a cape of Spain, on the W. coast of Galicia. N. lat. 38° 20′. E. long. 15° 23′.

MILBANK'S SOUND, an inlet in the North Pacific ocean, between Point Day and Cape Swaine.

MILBORNE-PORT, a borough-town and parish in the hundred of Honethorne, and county of Somerset, England. The former stands on one of the branches of the river Parret, at the distance of ten miles from Ilchester, and two from Sherborne, in Dorsetshire. This place is of great antiquity, having been a borough of considerable importance prior to the Conquest; after which event it lost much of its consequence, though it retained all its former privileges till the reign of Edward III., by whom it was deprived of the right of sending members to parliament. In the reign of Charles I., however, that franchise was restored; and it now returns two representatives, who are chosen by the inhabitants paying scot and lot. The government of this town is vested in the owners of nine bailiwicks, who are lords thereof, assisted by two deputy bailiffs, two constables, and several other inferior officers. Besides these there is likewise an association within the borough, consisting of nine persons, two stewards, and seven assistants, who are privileged to hold property in their corporate capacity, for the benefit of the poor.

The buildings of Milborne-Port are chiefly disposed in four streets, the principal one of which, called High Street, is of considerable width, but extremely irregular. In this street stands the guild-hall, an ancient edifice, having a door-case partly of Saxon and partly of Norman architecture. The old market-house is now converted into warehouses, and there is no regular market now held. The church, an ancient structure, built in the form of a cross, is surmounted by a very massive quadrangular tower, supported by two pointed and two semi-circular arches. In the north aisle are several handsome monuments, in honour of the Medlycot family. On opening a plot of ground near the church-yard, for the purpose of building, sixty bodies of men and women were discovered, arranged in regular rows, which, from the want of coffins, are supposed to have been buried at the time of the great plague.

Besides the borough, the parish of Milborne-Port contains two considerable villages, called Kingsburg-Regis and Milborne-Wyke. The former has land-tax and parochial assessments peculiar to itself; and there is held here an annual court-baron, wherein the lords' rents are paid, presentments made, and a constable, tything-man, and hayward appointed. The lands in this vicinity are mostly arable, and in a high state of cultivation and fertility.

According to the parliamentary returns of 1801, the total population of this parish amounted to 953 persons, 440 males and 513 females; of which number 577 were engaged in different branches of trade, and 200 in agriculture. Collinson's History and Antiquities of Somersetshire, vol. ii. 3 vols. 4to. Maton's Western Counties, vol. ii. 8vo.

MILBOURN, LUKE, in *Biography*, an English divine, was the son of Mr. Luke Milbourn, a nonconformist minister, who was ejected from the living of Wroxhall, in Warwickshire, in 1662, and died at Newington in 1667. His son received a good education, became master of arts, and obtained the rectory of St. Ethelburg in London. He published sermons and theological tracts, 2 vols. 8vo.; a poetical version of the Psalms; and several poems, for which Pope gives him a place in the Dunciad. He died in 1720.

MILCE, in *Geography*, a town of Poland, in Volhynia; 34 miles N.N.W. of Lucko.

MILDEN. See MOUDON.

MILDENHALL, a market-town and parish in the hundred of Lackford, and county of Suffolk, England, is situated on the river Lark, at the distance of 12 miles from Bury, and 70 from London. The parish is of great extent, from the dispersed arrangement of its streets, which in fact form a series of little villages. That part of the town called the Borough, or High-town Mildenhall, is its principal division, and contains both the church and the manor-house. The former is a very large and handsome structure, and has a rich roof of carved work, and a lofty tower, and contains a variety of monuments in honour of the family of the Norths. This church is supposed to be of very ancient foundation, and is much admired for its architecture. The manor-house, likewise an old edifice, but greatly altered and repaired of late years, constitutes the family residence of sir Thomas Charles Bunbury, bart., who was one of the representatives for the county in the last parliament. The ancient mansion of the Norths here has a gallery in front, extending the whole length of the house. This town was much injured by a fire, which broke out on the 17th of May 1507, and in a few hours consumed 37 dwelling houses, besides barns, stables, and other appurtenances.

Mildenhall is the chief town of the hundred, and, according to the parliamentary returns of 1801, contained a population of 2283 persons, 1095 males and 1188 females; of which number 390 were returned as engaged in agriculture, and 147 in different branches of trade and manufactures. The petty sessions are held here, as well as a weekly market on Friday. This town has furnished London with two lord mayors, Henry Barton and William Gregory; the former of whom held that honourable office in 1428, and the latter in 1451.

The vicinity of Mildenhall presents to the view a flat, open country, wholly devoid of any interesting features, except a few family-seats, the chief of which are Ickworth, Rushbrook, and Culford. Ickworth is distinguished for its noble park, which is no less than ten miles in circumference. Kirby's Suffolk Traveller, 8vo. 1764. Carlisle's Topographical Dictionary.

MILDEW, in *Agriculture*, a disease frequently destructive to corn, pulse, and other crops.

M. Duhamel ftates, that "it attacks the blades and ftems of corn, which it covers with a powder of the colour of ruft of iron, when at the height of their vegetation. This fubftance does not adhere ftrongly to the blades; for he has feen the hair of white fpaniels full of this powder, after they have run through a field attacked with this difeafe. It is likewife known, that if the infected wheat is wafhed by a plentiful rain, the ruft difappears almoft entirely, and the grain fuffers little from it. The French give it the name of ruft, from the colour of the powder, and it feems to be the fame diftemper, which the Roman writers term *rubigo*. He adds, that the caufe of this diftemper is ufually faid to be dry gloomy weather, happening while the corn is at the height of its vegetation; and in effect, he has many times obferved, that when a hot fun has fucceeded fuch dry hazy weather, corn was rufted within a few days afterwards. It is not common in clear, dry, hot years: but when the fpring is wet, the fineft fields of wheat run great hazard of being deftroyed by it, which generally appears upon the breaking out of the fun in the morning, after clofe and fultry weather, during which there has not been any dew. The rufty powder then gathers upon the blades in fuch quantities as to cover the earth around. M. de Chateauvieux cut off the mildewed blades, and found the trial anfwer: the fame plants produced new blades, and throve much better than thofe on which this operation had not been performed, but this cannot be done, except when the corn is very young. It is very fatal; as the fineft wheat is fuddenly brought almoft to nothing, when it is entirely attacked with it.

"If it attacks the plants while they are young, and before their ftems begin to rife, the mifchief is fometimes not very great, provided there comes on a feafon favourable to their farther growth. In this cafe they are only weakened, as if they had been fed or mowed. They fhoot out anew, and produce ears; though their ftraw is fhorter, and thofe ears are fmaller than they would otherwife have been. But if both blades and ftalks are mildewed at the fame time, the further growth of the plant is ftopt and the grain gets fcarcely any more nourifhment; fo that the crop is exceedingly diminifhed."

It was obferved that, "in the autumns of 1753 and 1754, when the corn was rufted, the fecond crop of hay was fo likewife. The grafs turned from a fine green to the ugly rufty colour of the corn: it was covered with the fame kind of powder, and its quantity diminifhed fenfibly every day; and as the whole of a field of corn is not ufually affected at the fame time, fo this diftemper extended only to fome parts of the meadow."

"The caufe of this diftemper is undoubtedly the fame in corn and in grafs; but its effect is not exactly fimilar. It may deftroy annual plants, fuch as corn, entirely; but in perennials, like grafs, it deftroys only the leaves or blades. May not the prefervation of thefe laft be owing to the taking off thofe leaves or blades, when they are cut for hay? But this is only conjecture; for it is confeffed, that he has not yet made any obfervation on this head.

It may be noticed that thefe caufes are far from being fatisfactory; but it is a difficult enquiry, and one which has lately, efpecially by botanical writers, been confidered in a very different point of view. The facts that have been lately prefented to the public on this fubject, fhew that it is not much influenced by foil, fituation, or the nature of the climate. The anfwers that have been given to different enquiries on this matter, may probably lead to fome ufeful conclufions. On this fubject Mr. Chatterton ftates, in the 44th volume of the Annals of Agriculture, that "1. From what he has feen, and heard from others, it appears that all foils in his neighbourhood, Yorkfhire, have had mildewed crops upon them; but as far as he can judge, the heavy clays, which had a good fallow, have efcaped the beft." But it is afterwards obferved, that though "this was the cafe in fome parifhes about him, yet, for the moft part, in the Eaft Riding they fuffered more feverely than any others, upon whatever foil: the reafon feems to be, that in general they were more luxuriant, and laid fome time before they were ripe. And he alfo underftands that crops on all foils (where thrown down) were the moft affected with the difeafe, if it may be fo called; from which it fhould feem not to arife from any previous caufe, fuch as the feafon of fowing, the difference of feed or manure, &c., but from fome uncommon bad ftate of the atmofphere not long before harveft, which moft affected the ftraw that refted in an horizontal pofition. He has further learned from a perfon, who fays he cut a field of wheat, which was affected with the mildew, while in a green ftate (but not before the grain had arrived at a good degree of folidity), and that it is much better corn than others which were fuffered to ftand till ripe. On the fea fide, there appeared juft before reaping time, but little (in comparifon) damaged in the vicinity of the beach; yet two or three miles from the fea, it feemed as bad as in other places at a greater diftance; and he has known, when all the gardens have been ruined by frofts in the fpring, at a diftance from the fea, while thofe upon the edge of the cliff have not fuffered at all."

And it is afterwards obferved, 2. That "both early and late fown crops have fuffered; but which have fuffered moft is hard to afcertain.

3. "That it is not eafy to fay, what fituations have been moft affected with mildew; it may be faid all are nearly the fame: he has obferved upon the wolds in Yorkfhire a great deal that would not pay for thrafhing; fo bad was it, that hens would prefer fhelling oats for their broods, rather than pick up the wheat that lay about them; and in the low lands at the foot of the wolds, both on ftrong and light foils, much of the ftraw appeared black in many fields.

4. "It is fuppofed, that both thick and thin fown crops have been equally affected.

5. "He imagines, from what he has heard, that old or new feed had no effect.

6. "That this fubject feems to be enveloped in myftery, as feveral perfons in this neighbourhood have had two fields of wheat adjoining each other—fituations and foils alike—management fimilar in every refpect, only not all fown at the fame time—yet both may be faid to have been fown in good feafon: the one field entirely efcaped the mildew, the other fo much damaged, that it was not worth thrafhing. Something might here be advanced on earlier or later fowing; but, perhaps, not any thing that could in the leaft guide the farmer in his future management, as feafons are fo various.

7. "That the crops of both kinds of land have fuffered feverely, and in fome places both have efcaped; without a general furvey, it is hard to decide.

8. "But he has not heard of any difference in crops arifing from difference of manure; he has not, however, inquired much into this matter.

9. "He has not heard of the different kinds of feed being different in regard to mildew."

And the refults of the inquiries of another writer in the fame work are, that in Lincolnfhire the foils moft liable to it, are 1. "In general light, loamy, and rich ones. 2. Late fown crops. 3. That there is very little difference in fituations, but if any, high ones have the advantage. 4. That the quantity of feed has little or no advantage; but drilling the

the feed has, on account of the greater and uniform depth. 5. That he never knew any difference between old and new feed, with regard to the mildew in wheat. 6. That he attributes the fole caufe of the mildew in wheat to mild winters, and to the inflammation of oxygen gas at the eve of harveft. 7 That fallow crops on ftrong clay foils have been leaft affected. 8. That all kinds of manures difpofe wheat to mildew in fuch feafons; lime in fome degree prevents it. 9. That he has no knowledge of the barberry having any effect at all upon wheat. 10. That no kind of wheat that he knows of, is exempted wholly from the mildew. 11. That early cutting from early fowing, has the greateft advantage, but not before the milk in the grain is completely coagulated."

It is alfo ftated, 1. "That in Staffordfhire Dr. Lewis made fome obfervations on the difeafe, and means of preventing it.

2. "That he does not think it of confequence to the queftion, at what time of the feafon wheat is fown, becaufe the period of the approach of the mildew cannot be even conjectured, as it has ever been variable. In this neighbourhood it fo happened, that the wheat which was fown in September and November 1803, fuffered in general more from the mildew, than that of October.

3. "That high and confequently ventilated fituations are doubtlefs more likely to receive a remedy to the difeafe, than low and fheltered ones; but he believes they were all equally affected.

4. "That it has not appeared, that any particular mode of fowing has been a prefervative to the crop. That drilled corn, rather than broad-caft, is more eafily cured, muft be granted, if the drill be wide enough to admit of a perfon to fet his foot between the rows, becaufe with a long pole, which, by means of ftraps, might be fufpended from his fhoulders acrofs his breaft to a proper height, he might brufh off the greater part of the dew, as he walked up and down, to the extent of three yards on each hand: and indeed, in a field of broad-caft, the fame means might economically be purfued, as it would furely anfwer to deftroy a part of the difeafed grain, which if left to itfelf would be good for but little, to fave the remainder. Thofe crops which were ftrong and thick, fuffered, in general, confiderably more than thofe which were thinner. 5. That it does not appear to him, that either new or old feed is of confequence to the queftion. 6. That the caufe exifts in the atmofphere, as he has already faid. He has no doubt, and he thinks, we may fairly conclude its being of that kind, which is termed phlogifticated; that particularly in the fummer it is fo loaded with the putrid effluvia of animal and vegetable fubftances, as to be incapable of attaining the height neceffary to undergo the chemical procefs of purification by the action of the vitriolic, nitric, and muriatic particles with which the air of the higher regions is charged; and that, therefore, it defcends in that undepurated and unwholefome fluid which we term mildew. It has frequently been obferved, that in thofe feafons, which have been preceded by a fevere winter, the air is more pure than when the winter has been mild; but whether the mildew has been more prevalent after a hard or temperate winter, has not yet made a part of his obfervation. Late frofts and fogs are generally reckoned inimical to vegetation, though he never heard it fuggefted, that they are in any degree connected with the fucceeding mildew. That crops on fallows and thofe on layers have fhared an equal fate. 8. Nor has there been any difference in confequence of different kinds of manure. 9. That the barberry tree is of fuch rare growth in this parifh, that if it had any effect upon wheat, it could not but have been afcertained long fince, beyond controverfy; but, when once an idea has gone abroad, every inftance in favour is deemed a proof, while the many in contradiction are never advanced. He hefitates not to pronounce, that it has *no effect* on wheat. Mr. Barker of Congreve had laft year, within 50 yards of his barberry tree, one of the beft crops of wheat in this neighbourhood; while Mr. Keeling, his next neighbour, at 200 yards diftance from the fame tree, and near no other, had a crop as bad as Mr. Barker's was the contrary. He knows not of five barberry trees in this parifh, but there were more than 50 times as many bad crops; which proportion he dare venture to fay, will be found to bear throughout England. How then can it be concluded, that the tree is fo peculiarly pernicious in this inftance? Since writing the above, he has received an acconnt of Mr. Makerell, who lives in the parifh of Brewood, having had a fine piece of wheat, not in the leaft affected by the mildew, though immediately in the vicinity of a hedge almoft entirely compofed of barberry bufhes. 10. He has never either feen or heard of any exception in favour of wheat of the bearded kind, nor indeed of any other; nor yet that any one fort fuffered particularly. 11. That as the mildew totally prevents thofe ears, which it affects, from coming to any perfection, it does not ftrike him, that the period of its being reaped can be of any confequence, and if not it muft be beft to let it ftand till the ftraw has received its full benefit."

And the ftatements of Mr. Lumbert on this fubject are, "1. That no foil is peculiar to the mildew. 2. That late fown crops have generally fuffered moft; but there have been inftances of the reverfe. 3. That low and fheltered fituations have fuffered moft; but this has been, perhaps, attributable to the wheat growing more luxuriantly, from its fituation, than the ftamina of the land could fupport when it was arriving at maturity: to this may be added a want of ventilation. 4. That a huge crop may be confidered a caufe of mildew; for an unkind feafon, or want of ftamina in the land, may check the vegetable mucilage before the corn is completely filled, and thereby produce a predifpofition to mildew. 5. That no difference is obferved in new and old feed, where the fituations have been fimilar. 6. That the firft caufe of mildew is a predifpofition in the wheat. This predifpofition is created by a decreafe of mucilage in the ftraw, which allows the watery particles to infinuate themfelves, and ftill further check the circulation of the juices in the ftem that are neceffary to the perfection of the grain, and had before become languid from the unkindnefs of the feafon, or the feeblenefs of the foil. When the watery particles have infinuated themfelves, the ftraw becomes difcoloured, and he has no doubt but a complete putrefaction would immediately fucceed it, if it were not prevented by a circulation of air. At all times during its growth, barley and oat ftraw appears to have fufficient mucilage in itfelf to refift the effects of the watery particles; but when it is cut it becomes like the ftubble in the fields, and cannot much longer refift it. 7. That fallows and layers have been equally liable. 8. He has obferved, that an over luxuriant growth in the fpring is favourable to the mildew, and has noticed that that luxuriance may be produced by particular manure, fuch as green vetches ploughed in, &c. which feem to caufe a confiderable fermentation in the foil, and produce a rapid vegetation for a fhort time. 9. That early cutting and laying down is moft clearly beneficial; and if the wheat is feverely affected, it is almoft impoffible to cut it too foon."

And farther, the facts collected by profeffor Balfamo in

Sicily,

Sicily, and detailed in the fame work, lead to the fame conclufions. For he ftates it as "evident that the mildew was common to the grain of all Sicily, without exception of kind, of foil, expofition, or other circumftances. It attacked, in different degrees, the barley, oats, and the plants of meadows; almoft all plants, whether fpontaneous or cultivated: and this confideration proves to him that the opinion which attributes the diftemper to fogs and dews, is erroneous; nor is it at all probable, that any meteor fhould, *at one time*, be the caufe, in places which, from the vicinity of mountains, rivers, and a multitude of other circumftances, had a very different climate from each other; and from the obfervations regiftered at the Royal Obfervatory, it appears, that, as every one knows, the fogs were rather heavier and more frequent in April and May 1803, when no mildew enfued, than in the fame months in 1804, when the great mifchief followed. And many cafes have occurred to him of fpots peculiarly given to fogs, and from which the countrymen argued a ruinous mildew, yet bright and clear crops were produced, while fpots more free from fogs have been attacked." The fame reafoning may "be applied to dews; thefe are more frequent and copious in the vicinity of rivers and ftagnant waters, than in other places; and it is true, that in many of thefe laft, and in more than one of the firft, the grain better refifted the mildew. Brucato is a humid diftrict, wafhed by rivers, and chequered by marfhes, which render the air infalubrious; yet it produced this year of mildew a reafonable crop of grain. And he obferved at Margana, that the wheat upon a farm fituated on the banks of a river, and very humid, with a bad air, was generally better than in the neighbouring country of Vicari, notably more dry from its fituation. Grain that is thin upon the ground, is more fubject to mildew than that which from thicknefs retains much more of the dew." It is ftated that the "Abbé Rozier, in his voluminous Dictionary, fays, that the mildew is caufed by the drops of water formed by fogs and dews when diffipated by a hot fun; but in Sicily, the fun in April, and much more in May and June, is always active; and our fogs in May are proverbial." And "in travelling in the beginning of fummer, through the country, it is vifible, that the mildew, in its various degrees, is connected with the foil, and the divers methods of cultivation; but the variety of effects is myfterious and inexplicable, on the fuppofition that the caufe is external to the plant."

After fome remarks on the nature of the difeafe, Mr. Marfhall fays, that a certain prevention of it would be a difcovery worth millions to the country. "Until this be made, let the grower of wheat, not only endeavour to fow early; but let him look narrowly to his crop, during the critical time of the filling of the grain; and whenever he may perceive it to be fmitten with the difeafe, let him lofe no time in cutting it: fuffering it to lie on the ftubble, until the ftraw be firm and crifp enough to be fet in fheaves, without adhering in the binding places: allowing it to remain in the field, until the grain fhall have received the nutriment which the ftraw may be able to impart. Where wheat has been grown on 'lammas land,' and the ground obliged to be cleared by the firft of Auguft, crops have been known to be cut, 'as green as grafs,' and to be carried off and fpread upon grafs land to dry. Yet the grain has been found to mature; and always to afford a fine fkinned beautiful fample. Rye-grafs that is cut, even while in bloffom, is well known to mature its feeds, with the fap that is lodged in the ftems. Hence there is nothing to fear, from cutting wheat or corn, before the ftraw be ripe." The opinion of Mr. Young is likewife the fame; he therefore advifes the farmer to be very attentive to his wheat crops in July, as "they are every where liable to this fatal diftemper, which admits but of one cure or check, and that is, reaping it as foon as it is ftruck. The capital managers in Suffolk, know well, that every hour the wheat ftands after the mildew appears, is mifchievous to the crop. It fhould be cut, though quite green, as it is found that the grain fills after it is cut, and ripens in a manner that thofe would not conceive who had not tried the experiment, which he has done many times; reaping fo early, that the labourers pronounced he fhould have nothing but hens'-meat. They were always miftaken, for the fample proved good, while others, who left it longer, fuffered feverely. The fact is now pretty generally admitted."

It is further ftated by the firft of thefe writers, "that the operation of this difeafe is carried on by the fungus tribe, evidently appears, from the ingenious and perfevering labours of botanifts," as lately fhewn by fir Jofeph Banks. (See Blight.) "But fungi, it is equally evident, are an effect, not the caufe of the difeafe. They are the vermin of the more perfect vegetables; and faften on them, whether in a dead, or in a difeafed ftate; but feldom while they are in full health and vigour. Their minute and volatile feeds may be faid to be every where prefent, ready to produce their kind wherever they may find a genial matrix. Such, at leaft, appears to be the nature of the fungus, or fungi, of wheat; for it may be liable to the attack of more than one fpecies. In a dry warm fummer, which is well known to be favourable to the health, vigour, and productivenefs of the wheat crop, the feeds of fungi are harmlefs, fo long as the fine weather continues. On the contrary, in a cold wet feafon, which gives languor and weaknefs to the wheat plants, few crops efcape, entirely, their deftructive effects. A ftanding crop not unfrequently efcapes, while plots that are lodged in the fame field, efpecially in pits and hollow places, become liable to their attack. And, by the facts above ftated, we plainly fee, that even ftrong healthy crops may, in a few days, or perhaps in a few hours, be rendered liable to be affailed; not progreffively, as by an infectious difeafe; but at once, as by a *blaft* or *blight*. In the ftate of the atmofphere we are to look for the caufe of the difeafe, in a *ftanding crop*: and nothing is fo likely to bring on the fatal predifpofition of the plants as a fucceffion of cold rains, while the grain is forming. The coolnefs neceffarily gives a check to the rich faccharine juices which are then rifing towards the ear; and the moifture may, at the fame time, affift the feeds of the fungi to germinate and take root. Thus reafon and facts concur, in pointing out the caufe, and the operation of the difeafe. There appear to be two reafons why corn which happens to be ftruck with this difeafe, in a dry warm fummer, is expofed to exceffive injury; as facts pretty evidently fhew that it is. The habits of the plants render them more fufceptible of injury, their rich juices more liable to be checked; and the feeds of fungi, it is probable, are more widely, if not more plentifully, diftributed, by fuch a ftate of the air; than they are by a cool moift atmofphere. The natural event is too well known: and it is the bufinefs of art to endeavour to prevent it."

Confequently "if by cutting down the crop, as foon as it is found to be difeafed, the operation can be ftopped, as experience, in different inftances, has fhewn it may, the remedy is eafy. It may be afked, in what manner the remedy is thus effected. But to the practical farmer, the fact is all that is required. To him, it is equally indifferent, to know the operation of the remedy, as the operation of the difeafe. Thofe who have profited by the remedy here recom-

recommended, believe, that it 'kills the mildew.' And if it shall appear that the fungus of wheat requires a free supply of air to keep it alive, or in a state of health and vigour, the effect of cutting down the crop will be explained. It will perhaps be found, by experience, that the closer it is allowed to lie upon the ground, and the sooner it is bound up in sheaves (provided the natural ascent of the sap to the ear be not interrupted), the more effectual and complete will be the remedy. Further, on the evidence of attentive observation, if wheat, which has been attacked by this disease, be suffered to remain in the field, with the ears exposed, until it may have received the ameliorating influence of dews, or moderate rain (to soften, relax, and assist the natural rise of the sap), the more productive it will probably become. And it may be still further added, that grain which is cut while under-ripe, is less liable to be injured in the field by moist weather, than that which has stood until it be fully or over-ripe." And a "probable mean of prevention is that of inducing early ripeness (for reasons above offered): either by sowing early; or by forcing manures; or by selecting and establishing early varieties, of wheat most especially; as early varieties of pease, and other esculent plants, are raised by gardeners: a work which only requires ordinary attention; and which, it is hoped, will, without delay, be set about and encouraged by every attentive grower of wheat, and every promoter of rural improvements, in the united kingdom." The method of raising and improving varieties of which will be afterwards noticed. See WHEAT.

MILDEW, in *Gardening*, is a vegetable disease, very hurtful to different kinds of trees and plants. It is supposed to proceed from different causes: some consider it as a kind of thick clammy moisture, which falls on, or rather transpires from, the leaves and blossoms of plants, which, by stopping up the pores, prevents perspiration, and hinders their growth. But the author of "The Philosophy of Gardening" suspects it to be a plant of the fungus kind, which grows without light or change of air, and with its roots penetrates the vessels of the vegetables to which it adheres, which are probably previously diseased, and thus deprives them of their due nourishment. But what is commonly denominated mildew, is an insect which is frequently found in vast numbers feeding upon the effused moisture. In a treatise upon this disease by M. Segar, it is conceived to be of a very sharp corrosive nature, and by its acrimony to hinder the circulation of the nutritious sap, in consequence of which the leaves begin to fade, and the blossoms and fruit to be greatly injured.

It is conceived by the first mentioned author, that the best method of removing it is by admitting more light and air, by proper thinning or pruning, so as to restore the natural vigour of the plants.

It is noticed by Mr. Forsyth, that, "contrary to the common opinion, trees are more liable to mildew on south and west walls, than on an east wall;" and that he has frequently removed such trees from a south or west wall, to a north or east wall, where they have frequently recovered.

It is advised, that "whenever danger is apprehended, to wash or sprinkle the trees well with urine and lime-water mixed; and when the young and tender shoots are much infected, to wash them well with a woollen cloth dipped in the following mixture, so as to clear them of all the glutinous matter, that their respiration and perspiration may not be obstructed.

"Take of tobacco one pound, sulphur two pounds, unslaked lime one peck, and about a pound of elder-buds; pour on them ten gallons of boiling water; cover it close, and let it stand till cold; then add as much cold water as will fill a hogshead. It should stand two or three days to settle, when the scum may be taken off, and it is fit for use.

And "there is a sweet saccharine substance found on the leaves of certain trees, which is generally but erroneously supposed to fall from heaven like dew. It is known by the title of *honey-dew*. There are supposed to be two kinds of it, one of which," Mr. Forsyth thinks, "transpires from the leaves of the trees where it is found; and the other is the excrement of a small insect called a vine-fretter, a species of the aphis. Bees and ants are very fond of both these kinds of honey-dew." As this exudation, "by its viscous quality, closes up the pores, and stops the perspiration of trees, it must of course be very hurtful to them."

This is a vegetable disease, which should, in his opinion, be treated in the same manner as the mildew, by washing at the same times.

The nature of mildew is more fully explained in speaking of it as relating to agriculture. See the preceding article.

MILDMAY, *Sir* WALTER, in *Biography*, the founder of Emanuel college, Cambridge, was surveyor of the court of augmentations in the reign of Henry VII., and privy counsellor, chancellor, and under treasurer of the exchequer in that of Elizabeth. He is celebrated for his uncommon merits in his private and public character. Sir Walter died in 1589.

MILDORFF, in *Geography*, a town of Austria; ten miles W. of Crems.

MILE', FRANCESCO, in *Biography*, born at Antwerp in 1644, was a very ingenious landscape painter, who made the heroic style of Nicolo Poussin his model, and succeeded to a very considerable degree in competition with him. In tones of colour he frequently surpasses him, and more nearly approaches Titian. He fails in the conception of scenery, and the composition of his forms.

He was poisoned, by some envious person, at the early age of 36 Had he been spared for a longer period, we may reasonably expect he would have completely rivalled his great predecessor.

MILE, in *Geography*, a long measure, whereby the English, Italians, and some other nations, use to express the distance between places. See MEASURE.

In which sense mile is used to the same purpose with league, used by the French and other nations.

The mile is of different extent in different countries. The geographical or Italian mile contains a thousand geometrical paces, mille passus, whence the term mile is derived.

The English mile consists of eight furlongs, each furlong of forty poles, and each pole of sixteen feet and a half: so that it is equal to one thousand seven hundred and sixty yards, or five thousand two hundred and eighty feet.

The mile employed by the Romans in Great Britain, and restored by Henry VII., was our present English mile. A degree of the meridian in England, N. lat. 52°, according to the late measurement of colonel Mudge, is 121,640 yards, or 69.114 miles. A geographical or sea-mile is the 60th part of such a degree, *i. e.* 2027⅓ yards; and three sea-miles make a league. A degree of the meridian in N. lat. 45°, as measured in France in 1796, is 57008 toises = 121512 yards = 69.092 English miles.

Casimir has made a curious reduction of the miles, or leagues, of the several countries in Europe into Roman feet, which are equal to the Rhinland feet generally used throughout the north.

The

		Feet.
The mile of Italy	——	50,000
of England	——	5,454
of Scotland	——	6,000
of Sweden	——	30,000
of Mufcovy	——	3,750
of Lithuania	——	18,500
of Poland	——	19,850
of Germany, the fmall		20,000
the middle		22,500

		Feet.
The mile of Germany, the largeft		25,000
of France	——	15,750
of Spain	——	21,270
of Burgundy	——	18,000
of Flanders	——	20,000
of Holland	——	24,000
of Perfia, called alfo parafanga		18,750
of Egypt	——	25,000

The following TABLE fhews the Length of Miles, Leagues, &c. Ancient and Modern, in Englifh Yards.

Ancient Roman mile	1610.348
Olympic ftadium = $\frac{1}{8}$th of an ancient Roman mile	201.2935
Stadium = $\frac{1}{10}$th of an ancient Roman mile	161.0348
Stadium = 1100dth part of a degree	111.2
Jewifh rifin, of which $7\frac{1}{2}$ = an ancient Roman mile	214.713
Gallic leuca = $1\frac{1}{2}$ ancient Roman mile	2415.522
German raft, or common league in France = 2 Gallic leuca	4831.044
Perfian parafang = 2 Gallic leagues	4831.044
Egyptian fchœne = 4 ancient Roman miles	6441.392
German league, or that of Scandinavia = 2 rafts	9662.088
The mile or league of Germany = 200 Rhenifh yards	8239.846
Great Arabian mile, ufed in Paleftine in the time of the crufades, rated at $1\frac{1}{2}$ ancient Roman mile	2415.713
Modern Roman mile	1628.466
Modern Greek mile of 7 Olympic ftadia	1409.0545
Modern French league = 2500 toifes	5328.75
Mile of Turkey, and the common werft of Ruffia, fuppofing it feven Olympic ftadia	1409.0545
League of Spain = 4 ancient Roman miles	6441.392
Large league of Spain = 5 ditto	8051.74

For other meafures of a mile, fee Tables under MEASURE.

MILE-*ftone.* This article is introduced folely for the purpofe of fuggefting an improvement under the title of *Mile-hut.* The comfort and convenience which travellers derive from mile-ftones is well known, and the dilapidations which they are fubject to, are very generally felt as a grievance. Inftead, however, of pointing out remedies for the evil (which might eafily be done), we wifh to fee them entirely fuperfeded by fubftituting mile-huts in the place of them. In every new act of parliament for a turnpike-road, or in any amended act, let it be a ftanding order that a claufe fhall be introduced, obliging the truftees to erect mile-huts on the whole line of road.

They fhould be uniform and cheap; the whole coft not to exift forty pounds: they fhould be lime-whitened in the manner of the buildings in South Wales. The door to be the place of meafurement, over which a painted board, with letters and figures very legible, denoting the place, thus, $\left\{\begin{array}{l}\text{London 5 ☜}\\ \text{Barnet 6 ☞}\end{array}\right\}$, and underneath the name of the cottager, "Jones," in a different character. Each hut fhould be furnifhed with hammers, a faw, a fcrew-wrench, nails, cords, twine, and fundry parts of harnefs to be paid for at low fixed rates by thofe requiring them, and the keepers to be under fimilar regulations for good behaviour as toll collectors. In winter each hut to have a lamp burning all night.

The advantages attending fuch a plan are more than can readily be conceived. It would infure a large fupply of cheap cottages all over the kingdom, and would be particularly convenient for the labourers who repair the roads, who would never be more than half a mile, when at work, from their home. The truftees would be fufficiently remunerated by an abatement in the wages, or an eafy rent to the occupier. Coaches, horfes, and every fort of travellers meeting with accidents, or needing affiftance, would always be within half a mile of help, and a certain knowledge of where it was to be had. But it is needlefs to enlarge, and all we wifh is, that fome member of parliament would endeavour to get the experiment tried upon fome one ftage, and we have no doubt it would foon come into general ufe.

MILECZA, in *Geography,* a town of Lithuania, in the palatinate of Wilna; 76 miles E. of Wilna.

MI-LEI, a town of China, of the fecond rank, in the province of Yun-nan. N. lat. 24° 34′. E. long. 103° 14′.

MILENT, a town of Pruffia, in the province of Pomerelia; 5 miles S.W. of Marienburg.

MILES, a Latin term, which, in its general import, fignifies *foldier.*

In our Englifh laws and cuftoms, miles is peculiarly appropriated to a knight, called alfo *eques.*

MILESARA, in *Geography,* a town of Afiatic Turkey, in the province of Diarbekir; 24 miles W. of Ourfa.

MILESBURY, a poft-town of America, in Mifflin county, Pennfylvania; 262 miles from Wafhington.

MILESIMO, a town of France, in the department of the Stura; 10 miles N.E. of Ceva.

MILETIN, a town of Bohemia, in the circle of Konigingratz; 12 miles N.N.W. of Konigingratz.

MILETO, a town of Naples, in Calabria Ultra, the fee of a bifhop; faid to have been built by the Milefians, after Darius

rius had destroyed their city. It was demolished by an earthquake in the year 1783; 22 miles S.S.W. of Squillace. N. lat. 38° 25'. E. long. 16° 25'.

MILETS, anciently *Miletus*, a town of Asiatic Turkey, on the W. coast of Natolia, once a celebrated city of Asia Minor, in Ionia. It was situated on the southern bank of the gulf into which the Meander discharged itself; but this river gradually accumulated its deposit in this gulf, that the town of Miletus was removed, in process of time, more than a league within the land. The town of Miletus was N. of the Posidæan promontory, S.E. of the promontory Trogilum, and W.S.W. of the town of Myus. This town was one of those which the Greeks conquered on their arrival in Asia. The mouth of the Meander, which was very distant from this town, was in the time of Pausanias under the walls of Miletus. This capital of Ionia was adorned with superb edifices, and was celebrated for its commerce, sciences, and arts. It had a grand temple of Ceres. The tomb of Nelleus, the son of Codrus, king of Athens, by whom the town was founded, might be seen near the walls, upon the way that led to the temple of Apollo Didymæus. This temple was burnt by Xerxes, but rebuilt by the Milesians on so large a scale, that, as Strabo reports, it was equal to a village in extent, whence it remained uncovered, but was surrounded by a thick grove, which was inhabited by the priests who served the temple. The citadel constructed by Tissaphernes, was situated on the isthmus which separated the ancient town from the new. The theatre, though built of stones, was cased with marble, and enriched with sculptures. Of all these superb edifices, there now remain merely mutilated marbles, half buried in the ground. Miletus was the native place of Thales, one of the seven wise men of Greece, and of Aspasia, the wife of Pericles. Venus had a temple at Miletus, and another in its vicinity. This city was anciently called Lelegeis, from the Leleges who inhabited it; afterwards Pitynda, from the quantity of pines which its territory produced; at a later period Anactoria; and last of all, Milesos, and in Latin Miletus. This town became illustrious by the number of colonies which proceeded from it. The Milesians, when free from a foreign yoke, were often reduced to a state of miserable vassalage by domestic tyrants. In the time of Antiochus II., king of Syria, we find that a person named Timarchus reigned in Miletus, and exercised great cruelties on the citizens, till he was driven thence by that prince, who, on that account, was honoured by the Milesians with the surname of Θεος, or God. This town lies at the distance of 64 miles S. of Smyrna. N. lat. 37° 22'. E. long. 27° 13'.

MILFOIL, in *Botany*, and the *Materia Medica*. See Achillea.

MILFORD, or Milford *Haven*, in *Geography*, a sea-port town situated in the parish of Stanton, hundred of Rhôs, and county of Pembroke, South Wales, is of very modern origin, having been founded since the year 1790, and raised to its present importance by the patriotic exertions of the honourable Mr. Greville, nephew to the late sir William Hamilton, on whose property it stands. Happening to be here with his uncle in 1784, the penetrating and scientific eye of Mr. Greville quickly perceived the many natural advantages which this situation offered for a naval and commercial establishment. He accordingly prevailed upon sir William to apply to parliament for an act to enable him to set out legal quays, establish markets, construct docks, and in general to do every thing necessary for insuring the prosperity of the intended town. This object being effected, the conduct of the undertaking was entirely committed to Mr. Greville, who immediately laid out the ground in allotments, according to a regular plan, and began his labours by the erection of a large inn or hotel. Numerous purchasers quickly appeared, so that in less than ten years the town had made considerable progress, and began to assume an air of neatness and consequence. Since that period Milford has continued gradually increasing in extent and importance. Many improvements have been made in the haven for the greater safety and accommodation of the shipping; and a dock-yard has been formed at the suggestion of lord Spencer, where several large vessels of war have been built and others repaired.

The situation of this town is most singularly beautiful, being seated on a small promontory, the sides of which descend gently to the water. The principal haven stretches itself to the south, and presents the appearance of a spacious lake. This harbour is one of the safest and most commodious in the world, and contains sixteen creeks, five bays, and thirteen roads, where upwards of a thousand sail may ride in perfect security. The town at present consists chiefly of three streets, with crossings, running in a direction from east to west, and parallel with the shore of the haven. At the extremity of the lower row of houses stands the church, an handsome edifice, consisting of a nave, chancel, and two side aisles. Several of the windows in this church exhibit escutcheons of painted glass, displaying the arms of Barlow, Hamilton, and Greville. In the chancel stands an ancient vase of red porphyry, brought from Egypt by the learned Dr. Pococke, and intended for the baptismal font, but that idea not coinciding with the religious feelings of a considerable part of the congregation, another of Derbyshire marble was fixed opposite to it for that purpose. Near the vase is placed a trunk of the mainmast of the L'Orient, the French admiral's flag ship, which was blown up at the battle of the Nile. At a short distance eastward from the church stands the old chapel of St. Catharine, formerly dependent upon Stanton, the mother church. It is a very ancient building, having the nave vaulted into a pointed roof; and since the erection of the new chapel has been converted into a powder magazine. The market-house is a very neat structure, as is likewise the custom-house; the collection for which takes in both sides of the haven from Milford town to the harbour's mouth, and round the coast of Bride's bay to St. David's. Two batteries for the defence of the town and haven have been lately erected, each of them mounting seven guns.

Milford is now the regular port for the mails from England to Waterford, for the conveyance of which five packets are stationed here, so that a daily communication is thereby kept up with Ireland. The chief trade of the town is its South sea whale fishery, which is carried on with great success by a colony of Quakers from the island of Nantucket, who were invited to settle here by Mr. Greville. They are, like most of their brethren, an industrious and well-disposed people, and have greatly contributed by their exertions to the progress of the new establishment. There is, likewise, some trade in wood and other stores requisite for the equipment or supply of his majesty's ships, or other vessels which may find it necessary to put in here for repair or safety. There are two quays for the landing of goods, and extensive storehouses for their reception, under the management of established officers. Two markets are held in this town during the week, on Tuesday and Saturday, but there are no fairs. The family of Philips derive from hence the title of baron. For the encouragement of the science of ship-building a boat-race was some years ago established here under the auspices of lord Cawdor and Mr. Greville. The prize for the winning boat of the first class of twenty feet keel, is a

cup

cup given by his lordship of the value of twenty-five or thirty pounds; and there is besides an inferior prize for boats of a second class from sixteen to eighteen feet keel.

The neighbourhood of Milford exhibits a well inclosed and highly cultivated country. Several elegant villas belonging to the merchants of Milford contribute much to its beauty. The old town of Haking stands on the W. side of the influx, call Priory Pill. Near it is an elegant observatory built by Mr. Greville, and, with the mathematical school contiguous to it, were placed under the direction of Mr. Firminger, who was for eight years sole assistant to Dr. Maskelyne. Here are likewise the ruins of the priory from whence the inlet derives its name. This religious establishment owed its foundation to Adam de Rupe, or de la Roche, who appears to have been a man of power and consequence in this district. It was dedicated to St. Mary and St. Buddoch for monks of the order of Tyrone, who in time forsook that strict rule and became Benedictines. A small portion of this edifice only now remains; most of the materials of which it was composed having been carried off within the memory of man, to assist in the erection of other buildings in the neighbourhood. The earl of Richmond, afterwards Henry VII., is said to have landed at this place, in his enterprise against Richard III., on the seventh of August, 1485. On the eastern side of the Pill, or influx, stands Castle Pill, which was formerly a fortification for its protection. In the reign of queen Elizabeth it was reckoned among the castles in Pembrokeshire; and is mentioned, in 1644, as one of the strongest posts which the royalists maintained in this part of the country. From the misconduct of the garrison, however, it was subsequently taken, after a short resistance, by a force apparently inadequate to the undertaking. The village of Stanton, which gives name to the parish in which Milford is situated, lies on the road between that town and Haverford-west. The church here was garrisoned during the civil wars by the troops of the parliament, with the view of interrupting the communication between Haverford-west and the fort already mentioned. According to the parliamentary returns of 1801, the whole population of this parish amounted to 1291 persons, a great proportion of whom resided in Milford. Fenton's Historical Tour through Pembrokeshire, 1 vol. 4to. Carlisle's Topographical Dictionary of Wales, 1 vol. 4to.

Milford, a township of America, in Mifflin county, Pennsylvania.—Also, a small town in Worcester county, Massachusetts, 18 miles from Worcester, containing 907 inhabitants.—Also, a post-town of the state of Delaware, pleasantly situated on the N. side of Maspilion creek, about 12 miles W. of its mouth in Delaware bay; containing more than 100 houses, inhabited by Episcopalians, Quakers, and Methodists.—Also, a town of Northampton county, Pennsylvania, laid out on the N.W. side of the Delaware, in an elevated situation, at Well's Ferry, 120 miles above Philadelphia. A paper-mill has been erected here by a Mr. Biddis, who has discovered the method of making paper and pasteboard by substituting a large proportion of saw-dust in the composition.—Also, a post-town of Connecticut, in Long-island sound, and in New Haven county, 13 miles S.W. of New Haven. The Indians call this town "Æopowage;" and it was settled in 1638. It contains an episcopal church, and two congregational churches.

Milford *Haven*, a deep bay on the coast of Nova Scotia, to the S.W., round the point of the strait of Canso.—Also, a bay on the N. coast of Virginia. N. lat. 37° 26'. W. long. 76° 20'.

MILHAU, a town of France, and principal place of a district, in the department of Aveyron, seated on the Tarn. In 1371, this town was taken by Edward III., king of England; 27 miles S.E. of Rodés. The place contains 6077, and the canton 10,443 inhabitants, on a territory of $297\frac{1}{2}$ kiliometres, in nine communes. N. lat. 44° 6'. E. long. 3° 10'.

MILHAUSEN, a town of the duchy of Stiria; 10 miles E. of Gratz.

MILI, a river of Sicily, which runs into the sea, seven miles S. of Messina.—Also, a town of Thibet; 45 miles N.E. of Tchiatam.

MILIANI, a town of Africa, in the kingdom of Algiers; 22 miles S.E. Shershell.—Also, a river of Africa, in the kingdom of Tunis, which runs into the Mediterranean, about 10 miles S.E. of Tunis.

MILIARENSIS, in *Antiquity*, a silver coin of the empire, substituted by Constantine in the room of the denarius; and so called because he fixed the price of the pound of gold at 1000 pieces of this new silver. But as he divided the pound of gold also into 72 solidi, each solidus really contained $13\frac{8}{9}$ miliarenses, though it passed for 14; which difference between the real and current value of the solidus, in relation to the miliarenses, must have occasioned disputes in the payment of small sums. To remedy this inconvenience, it was thought proper to alter the weight of the silver money, and having fixed the price of the pound of silver at five solidi, to coin sixty pieces out of it, which retained the name miliarenses, though the pound of gold was worth but 864. It does not appear how many miliarenses Constantine coined out of the pound of silver: but if the piece of gold was nearly the same in his reign, as when five solidi were worth a pound of silver, the pound must have been worth $14\frac{2}{5}$ pounds of silver; and 1000 divided by $14\frac{2}{5}$ gives $69\frac{4}{9}$ for the number of miliarenses coined out of the pound. Therefore it is probable, that Constantine's number was either 69 or 70. If the former, each piece should weigh $73\frac{8}{23}$ troy grains; if the latter, $72\frac{3}{16}$. According to the former estimate, the proportion of gold to silver was always $14\frac{1}{2}$ to 1; according to the latter, $14\frac{2}{7}$ to 1. Phil. Trans. vol. lxi. part ii. p. 513. See Follis.

MILIARES Glandulæ, in *Anatomy*, glandular bodies distinguished by their small size; such as the supposed glands of the skin, &c.

MILIARIUM, the name of a tall and narrow vessel, used in the bathing of the ancients, for heating water to any degree, to give warmth to the rest. See Mem. Acad. Inscript. vol. i p. 127.

MILIARY Eruption, in *Medicine*, an eruption of minute vesicles, appearing in persons confined to bed, in hot and close apartments, especially after profuse sweating. The term has been adopted from ancient times, from the resemblance of the vesicles in size and appearance to *millet* seeds.

Miliary *Fever*, a denomination given to fevers of every description, when accompanied by an eruption of miliary vesicles.

This is the light in which the more correct observation of our times has taught us to consider the *miliary fever*. The physicians of the seventeenth and the greater part of the eighteenth century describe the miliary fever, as a distinct eruptive fever, arising, like the small-pox, measles, &c., from a peculiar poison or acrimony, of the proper concoction and expulsion of which from the system the eruption was deemed evidence, according to the doctrines of the humoral pathology. Under this notion, the disease was described, by different observers, with a variety of titles, and no small degree of confusion arose from the misapplication of these titles to other diseases, which bore some resemblance to it. Thus,

Thus, it was called, the miliary disease (Morbus miliaris), the miliary fever, the vesicular fever, or simply *miliaria*, and *milliaris*, and others, confounding the vesicular appearances with the purple spots, or petechiæ of malignant fevers, or supposing them to be of a similar nature, applied the term *Purpura* to it; calling it Purpura alba, Purpura miliaris. Febris purpurata, &c. Again, another mistake, equally gross, was committed in places where the scarlet-fever was epidemic, in confounding the rash of this disease with the vesicular eruption of miliaria. This occurred particularly at Leipsic, where *scarlatina* was extremely prevalent and fatal, in the year 1652, and a history of which was published by Christ. Joan. Langius. (See his Prax. Med. part ii. cap. xiv. § 9.) This fever was extremely contagious, and spread over the greater part of the continent, and was called a miliary fever; it has been even considered by many writers as the prototype of all miliary fevers, and the first example of its appearance in Europe. See Macbride, Method. Introd. to the Theory and Pract. of Physic, part ii. chap. xvii. Hamilton de Febri Miliari. Allioni Tract. de Miliarium Orig. Progress. &c. J. Fordyce Hist. Febris Miliaris, &c.

These errors were corrected by De Haen (De Divis. Febrium, § 4.); and the true nature of the miliary eruption, as always secondary or symptomatic, and as the result of perspiration and of a continued heating regimen, in various febrile diseases (of which, indeed, Sydenham had long before expressed his belief), was satisfactorily shewn by Mr. White (in his Essay on the Management of Lying-in Women), and by Dr. Cullen (Nosol. Method. Gen. xxxii. *note*.) In truth, the occurrence of this eruption, and of the severe and often fatal symptoms of fever, with which it was accompanied, affords a lamentable proof of the mischief resulting from mistaken hypothesis on medical subjects, when carried to the bedside of the sick. For this *miliary fever* has been, at different times and places, not only produced, but actually rendered epidemic, by the mal-practice of individuals. Mr. White asserts, that a midwife at Manchester, who had very extensive practice among all ranks of women, and was tolerably successful in other respects, had a remarkable number of her patients seized with the miliary fever, during their accouchement, which proved fatal to many, particularly to the wives of several of the principal tradesmen. This disease "became so alarming and notorious, both in this neighbourhood and in distant parts of the country, as to acquire the name of the Manchester fever." While at the same time, other practitioners of the place, who pursued a different plan of treatment, met with no such fever. So that the sarcasm of Dr. Shebbeare was but too correct, when he recommended gentle means of supporting the vital heat, "otherwise the miliary eruption may be rather a symptom of the physician than of the disorder, as it is to be feared that some, through mistaken practice, have discovered a way of *making* miliary fevers, and may be called a kind of manufacturers of that disease." (Practice of Physic.) "Quid verò demum generi humano calamitosius," says De Haen, "quam quod et plebe et medicis conspirantibus, tot milleni quotannis ægri, ab ipso principio acutorum, in sudores symptomaticos agitentur, ac veluti fundantur, ut coacta omnino crisis, in plerisque aut letalis, aut periculosa saltem, producatur; interea dum salutaria naturæ molimina turbantur, confunduntur, ac penitus sufflaminantur. Faxit DEUS, ut demum sapiant Phryges!" Fe Febrium Divis. § 4. p. 84.

Hippocrates and the ancients have said little respecting this miliary fever, because they followed too steadily the dictates of nature in their practice to produce it. They do, however, mention a casual appearance of miliary vesicles, in febrile diseases. (See Hippocrates Epidem. lib. i. § 3. ægrot. 2. lib. ii. § 1. & § 3.) In like manner, those practitioners who have been conversant with the treatment of diseases during the last thirty years, have witnessed but casual and slight occurrences of these eruptions, and are totally unacquainted with the formidable miliary fever, described by the physicians of Leipsic, and subsequently very well known in this country.

It has been universally observed that women, during their puerperal confinement, although not exclusively, were the most frequently attacked by the miliary fever. This, no doubt, arose from the peculiar assiduity with which the hot and sweating regimen was enforced with puerperal women, of which Mr. White has given an impressive description. (Loc. cit. p. 6. et seq. 3d edit.) Under the suffocating heat and closeness of the room, in which was a large fire and a crowd of people, and every crevice, even the key-hole, closed; under an additional load of bed-clothes, from which the good woman was not allowed to put out her arm, or even her nose; and constantly supplied with heating liquors from the spout of a tea-pot to keep up the sweating; in such a situation, "a few days after delivery the patient is, perhaps, seized with a shivering fit, and the nurse is surprized, as she protests she has not had the least waft of cold; more clothes are heaped upon her; spirituous liquors and hot spices are given her, to throw off the cold fit, which most certainly increase the succeeding hot one. A warm room, plenty o clothes, and warm drinks are continued, to throw her into a sweat, but have frequently a contrary effect, by increasing and prolonging the burning fit; which at last terminates in a most profuse sweat, continuing many nights and days without giving relief." (Ibid. p. 13.) The tongue becomes dry and warm; the pulse quick, small, and creeping; and the patient complains of great anxiety and oppression about the præcordia, attended with sighings, lowness of spirits, lassitude, and extreme languor and debility. "If the hot regimen be continued," Mr. White proceeds to state, "with vinous spicy caudles, hot alexipharmic medicines, volatile alcalious salts and spirits, opiates, and a close room, so as to keep the patient in a perpetual sweat, vibices or petechiæ appear, or (miliary) eruptions, either of the white or red kind, or both, first upon the neck and breasts, afterwards extending themselves all over the body, one crop succeeding another till the patient is worn out; but they give no relief, are not in any way critical, nor is there indeed any crisis in this disorder, except the looseness." (P. 16.) In the miliary fever, which was epidemic among puerperal women at Leipsic, about the year 1650, many of the most violent symptoms, connected with malignant fever, concurred; such as extreme prostration of strength, restlessness, and delirium, tremors and convulsive motions of the limbs, dimness of sight, hæmorrhagies, &c. (See Gotofr. Welsch, Hist. Med. Nov. Morb. Puerp. qui *der Friesel* dicitur:—in Haller, Disput. Med. tom. v. § clxxiv.) The disease is said to have been called *der Friesel*, from the resemblance of the rough state of the skin, to a sort of cloth called *friess*.

The utmost irregularity seems to have prevailed, in respect to the period at which the miliary vesicles made their appearance. According to Welsch, it appeared as early as the second day after parturition, or within the first week: but other writers have not seen it before the fifth day, and others again on the seventh, eighth, tenth, or eleventh, on the fourteenth, sixteenth, and even twenty-eighth day. This difference would, of course, be expected to happen, in consequence of the different degrees of the hot regimen adopted in in different inſtances, and of the variety of ſeaſon and of individual conſtitution. It ſeems to be agreed, however, notwithſtanding the hypothetical notions of the ſalubrity of ſuch expulſions of ſuppoſed morbific matter from the body, that a favourable termination of the diſeaſe is not more certain from a copious eruption, or from its early appearance; but that, on the contrary, the fuller and earlier the eruption is, the greater is the danger.

The diſtinction that has been made by writers in general, reſpecting the two kinds of miliary veſicles, the *red* and the *white*, is futile; as theſe differences of colour are by no means ſpecific, but depend entirely upon the ſize of the veſicles, their tranſparency, and the degree of inflammation accompanying them: inſomuch that the eruption which is *red* in the beginning, when the veſicles are perfectly diaphanous, becomes *white* in a day or two, when the inflammation of the ſurface is leſs, and the lymph contained in the veſicles becomes of a milky opacity.

Mr. White obſerves, that "the diſeaſes, or rather the ſymptoms, which are ſaid to ſucceed the miliary fever, are hectic heats, loſs of appetite and of ſpirits, and ſwellings of the legs, feet, and thighs; but theſe are nothing more than what follow other putrid fevers. Thoſe who have had this fever are particularly liable to returns of it during their whole lives; owing moſt probably to the ſkin being over relaxed, and its tone deſtroyed, by a too hot and forcing treatment."

Miliary eruptions have been produced in conſequence of feveriſh complaints, which confined patients to bed, and occaſioned a ſweating condition of the ſkin, as well as in the puerperal ſtate. Thus it has ſometimes occurred in perſons who became feveriſh after ſome important ſurgical operation, or remained in bed in conſequence of ſome accident; it has occurred alſo in catarrhal and rheumatic fevers, where the natural tendency to ſweating is conſiderable, and in various other febrile complaints. Hence we may explain the obſervations of ſome writers on the ſubject, who ſpeak of the miliary fever as imitating or being diſguiſed under the character of other febrile diſeaſes; when, in fact, the eruption was ſecondary, and had ſupervened upon the hot and ſweating ſtate of the patient in thoſe other fevers reſpectively; ſuch as tertians, quartans, remittents, &c. (See Memoires de la Soc. Royale de Medecine, par M. Barailon, tom. i. p. 193.) Indeed there is ſcarcely any acute diſeaſe, with which the miliary eruption has not been deſcribed as combined, and with which it might be expected to be combined, while the mode of practice, which gave riſe to it, continued to be purſued: thus it has been conjoined with typhus, gout, pneumonia, meaſles, ſmall-pox, ſcarlet-fever, hooping-cough, the fever of dentition, aſthma, &c. See Allionius Tract. de Miliarium Orig. Progreſſ. Nat. et Curat. The Cure of the Miliary Fever, by a ſubject to Mithridates.

That excellent writer, Dr. Macbride, was miſled, like his leſs intelligent brethren, by the prevalent hypotheſis of the concoction and critical expulſion of morbid acrimony, and conſidered miliary fever as ſomething ſpecific, like the contagious eruptive fevers. He has accordingly deſcribed it, as occurring alone and uncombined, under the term *miliaris ſimplex*, ſeu *benigna*. "The febrile ſymptoms previous to the eruption," he ſays, "are not very high nor diſtreſſing; no great pain, thirſt, or ſickneſs; the pulſe rather depreſſed than hard; they increaſe, however, gradually till the third or fourth day, when the eruption ſtrikes out, chiefly on the neck, back, and breaſt, being preceded by a profuſe ſweat, of a ſouriſh ſmell, and a particular tingling ſenſation in the ſkin, eſpecially in the fingers, and an itching in thoſe places where the miliary puſtules (veſicles) are moſt plentiful. In about thirty hours the eruption is full out, and replete with ſerum, with a ſlight inflammation round the baſis of the little veſicles, occaſioning a fulneſs and tenſion of the ſkin. The febrile ſymptoms now ſubſide, the patient continues to ſweat plentifully, and makes higher-coloured urine, the pulſe gradually becomes full, ſoft, and equable, and by the end of the week the eruption dries up, and the cuticle falls off in ſcales." (Methodical Introd. to Theory and Pract. of Phyſic, part ii. chap. 17.) Sir Richard Blackmore gives a ſimilar account of the progreſs of the miliary eruptions, the drying of which, "in the more kindly ſort, is generally accompliſhed in ſeven days." (Treatiſe on the Plague.) But in the worſe ſorts, he ſays, the time is much protracted; and he avers, that he has ſeen the fever continue, and a ſecond, and even a third crop of the eruptions appear, and go through the ſame courſe. And Dr. Brockleſby mentions a caſe, in which the low pulſe, great proſtration of ſtrength, and other ſevere ſymptoms, continued *forty-ſix days*, in which time *four* ſucceſſive crops of miliary veſicles occurred. See his Paper on Seltzer Water, Med. Obſ. and Inquir. vol. iv. art. ii. p. 31.

Having ſtated theſe facts upon the authority of the beſt writers on the ſubject, it is ſcarcely neceſſary to enter into any detail of the diſcuſſion, relative to the origin of the miliary fever. The ſagacity of Sydenham detected their efficient cauſe in the hot regimen generally practiſed in his time, and long afterwards. "Licet ſua ſponte nonnunquam ingruant, ſæpius tamen *lecti calore* et *cardiacis* extorquentur." (Sched. Mon. de Nov. Febris Ingreſſu.) And his opinion has been ſubſtantiated, and the arguments and hypotheſis of thoſe, who denied its truth, practically refuted by the almoſt total diſappearance of the diſeaſe, even in puerperal women, ſince the rational method of ventilation and regimen, now practiſed, became generally prevalent among medical men.

It is ſcarcely neceſſary, therefore, to ſay any thing reſpecting the method of treatment. In all circumſtances, under which a perſon is confined to bed, the room in which he lies ſhould be as free from any diſagreeable ſmell or cloſeneſs as any other apartment in the houſe; which can be readily effected by the conſtant admiſſion of freſh air and by cleanlineſs: and his bed-clothes, whether he labour under fever or not, ſhould be as light as may be, provided the ſkin is not cooled below the natural ſtandard of temperature, and the patient experiences no actual ſenſation of chillineſs. Theſe rules ſhould be ſtrictly obſerved, even under a ſtate of perſpiration or profuſe ſweating; for, ſo long as no direct current falls upon the patient, coolneſs of the ſurrounding air will moderate, without ſuppreſſing, the cutaneous diſcharge. Even when the miliary eruption has appeared, in conſequence of previous improper management, coolneſs of the apartment and bed of the patient, with a free acceſs of freſh air, will be found the moſt effectual cordial, and will ſupport the ſtrength, and ſubdue the languor of body and mind more powerfully than "gallons of wine." Conſult Mr. White's able treatiſe above quoted, in which references to all the writers on the ſubject are given, and from which, as well as the Eſſay of De Haen, de Diviſione Febrium, the moſt ſatisfactory information will be obtained.

MILICIA, in *Geography*, a river of Sicily, which runs into the ſea; 10 miles E.S.E. of Palermo.

MILIEU HARMONIQUE, in *French Muſic*, is the name ſometimes given to the 3d of a common chord or triad, as being the mean or middle between the key note or fundamental baſe and its 5th.

MILILLO, in *Geography*, a town of Sicily, in the valley of Noto; 8 miles S.S.E. of Lentini.

MILIN, a town of Bohemia, in the circle of Beraun; 4 miles from Przibram.

MILIOLUM, in *Surgery*, a small tumour of the eyelids, so called, from its being of the size of a millet seed.

MILIQUEAN CREEK, in *Geography*, a river of Upper Canada, which, running northerly, discharges itself into lake Simcoe, now called "Holland's river."

MILIS, a town of Sardinia; 12 miles from Oristagni.

MILITANT, a term used of the body of Christians, while here on earth.

The Romanists divide the church into militant, patient, and triumphant: the militant is on earth; the patient, or passive, they place in purgatory; and the triumphant in heaven.

MILITARE ÆRARIUM. See ÆRARIUM.

MILITARIS TOGA. See TOGA.

MILITARIS *Via*. See VIA.

MILITARY, something belonging to the militia, or soldiery. Thus,

MILITARY *Architecture* denotes the art of fortification. See ARCHITECTURE, and FORTIFICATION.

MILITARY *Art*, is the art or science of making or sustaining war to advantage. See WAR.

MILITARY *Column*. See COLUMN.

MILITARY *Court*. See COURT *of Chivalry*.

MILITARY *Discipline*. See DISCIPLINE.

MILITARY *Estate* includes the whole of the soldiery; or such persons as are peculiarly appointed among the rest of the people for the safeguard and defence of the realm. Although the laws and constitution of this kingdom know no such state as that of a perpetual standing soldier bred up to no other profession but that of war, it has for many years past been judged necessary by our legislature, for the safety of the kingdom, the defence of the possessions of the crown, and the preservation of the balance of power, to maintain, even in time of peace, a standing body of troops, under the command of the crown, who are however *ipso facto* disbanded at the expiration of every year, unless continued by parliament; and if from experience past we may judge of future events, the army is now lastingly engrafted into the British constitution; with this singularly fortunate circumstance, that any branch of the legislature may annually put an end to its legal existence by refusing to concur in its continuance. (Bl. Com. b. i.) The military force of the kingdom comprehends regulars, including the royal marines, the militia, and volunteers. See MARINES, MILITIA, SOLDIER, and VOLUNTEERS.

MILITARY *Execution*, the delivery of a city or country up to be ravaged and destroyed by the soldiers, upon its refusing to pay the contribution money imposed upon it. It denotes also the punishment inflicted by the sentence of a court martial. See EXECUTION.

MILITARY *Exercises* are the evolutions or various manners of ranging and exercising soldiers. See BATTALION, EVOLUTION, EXERCISE, and MANUAL *Exercise*.

MILITARY *Feuds*. See FEE and FEUD.

MILITARY *Fever*, a kind of malignant fever frequent in armies, by reason of the ill food, &c. of the soldiers. See FEVER, and TYPHUS.

MILITARY *Government*, is the supreme command and disposal of all the military power of a nation, by land and sea.

MILITARY *Law*. See LAW *of Arms*, and MARTIAL.

MILITARY *Machine*. See MACHINE.

MILITARY *Merit, Order of*, in *Heraldry*, was instituted in France, in the year 1759, by Louis XV. in honour of those officers of his army who were Protestants. The marks of honour are the same as those of the order of St. Louis. The ensign of the order is also of the same form as that of St. Louis, with this difference, that on one side is a sword in pale; within this motto—PRO VIRTUTE BELLICA; and on the reverse is a chaplet of laurel; within this inscription, LUD XV. INSTITUIT 1759.

MILITARY *Music*, before the introduction of fire-arms, served to animate the soldiers in battles and assaults of places, as well as for purposes of signals for the different manœuvres and duties in camp and garrison; and, therefore there is no reason to doubt its having been used in our ancient armies. The common military instruments of music were the trumpet, drum, fife, and horns of different kinds. See an account of each under its proper title. In modern times, kettle-drums and trumpets have been chiefly appropriated to the horse. The dragoons long had the hautbois and side-drum, but about the year 1759 changed these for the trumpet: the infantry had only the drum, till the introduction of fifes. Since the introduction of light infantry, many of these companies have used the bugle-horn.

Of late years, in addition to the drums and fifes, each regiment of infantry has had its band of music. The instruments are chiefly hautbois, clarinets, French horns, bassoons, trumpets, cymbals, and in some the tabor and pipe. The band is usually composed of men borne upon the establishment of the regiment as privates, and allowed some additional pay from the non-effective fund of the field-officers and captains of companies. These officers also defray the charge for instruments, extra-clothing, music, &c. though in many corps the money paid for discharges has been applied to the support of the regimental band. Grose's Mil. Ant. vol. ii.

MILITARY *Order*. See ORDER, and KNIGHTHOOD.

MILITARY *Pyrotechny*. See PYROTECHNY.

MILITARY *Rewards*. See REWARDS.

MILITARY *Tenures*. See TENURE.

MILITARY *Testament*, among the Romans, was what we call a nuncupative will; or a testament made only by word of mouth, in the presence of two witnesses.

This was a privilege peculiar to the soldiery, and to them only when in the field; for at other times they were subject to the common laws in this respect. See SOLDIER.

MILITARY *Townships*, in *Geography*, townships of America, in the state of New York; deriving their appellation from the following circumstance. The legislature of the state granted $1\frac{1}{2}$ million of acres of land as a gratuity to the officers and soldiers of the line of this state. This tract, forming the country of Onondago, is bounded W. by the E. shore of the Seneca lake and the county of Ontario, N. by the part of lake Ontario near Fort Oswego, S. by Tioga county, and E. by Chenango county. This pleasant country is divided into 25 townships of 60,000 acres each, which are again subdivided into 100 convenient farms, of 600 acres, amounting in the whole to 2500 farms, well watered by a multitude of small lakes and rivers.

MILITARY *Ways*, *viæ militares*, are the large Roman roads, which Agrippa procured to be made through the empire, in the time of Augustus, for the more convenient marching of troops, and conveyance of carriages.

N. Bergier has wrote the history of the origin, progress, and amazing extent, of these military roads; which were paved from the gates of Rome to the extreme parts of the empire. See WAY.

MILITELLO, in *Geography*, a town of Sicily, in the valley of Demona, on the N. coast; 16 miles S.W. of Pati.

MILITES CANDIDATI. See CANDIDATI.

MILITIA, a collective term, understood of the body of soldiers, or persons who make profession of arms.

The word comes from the Latin *miles, a soldier;* and *miles* from *mille,* which was anciently wrote *mile.* For in levying soldiers at Rome, as each tribe furnished a thousand, *mille,* or *mile, men;* whoever was of that number, was called *miles.*

MILITIA, in its proper and more restrained sense with us, is used to signify the inhabitants, or, as they have been sometimes called, the *trained-bands,* of a town or county; who are armed on a short warning for their own defence. In which sense militia is opposed to regular stated forces. Soon after the restoration of king Charles II., when the feudal tenures were abolished, it was thought proper to ascertain the power of the militia, to recognize the sole right of the crown to govern and command them, and to put the whole into a more regular method of military subordination; and the order in which the militia now stands by law, is principally built upon the statutes which were then enacted, *viz.* 13 Car. II. cap. 6. 14 Car. II. cap. 3. 15 Car. II. cap. 4.

It is true the two last of them are apparently repealed; but many of their provisions are re-enacted, with the addition of some new regulations, by the present militia laws; the general scheme of which is to discipline a certain number of the inhabitants of every county, chosen by lot, for three years, and officered by the lord-lieutenant, the deputy lieutenants, and other principal land-holders, under a commission from the crown. They are not compellable to march out of their counties, unless in case of invasion or actual rebellion, nor in any case compellable to march out of the kingdom. They are to be exercised at stated times; and their discipline in general is liberal and easy; but when drawn out in actual service, they are subject to the rigour of martial law, as necessary, to keep them in order. This is the constitutional security, which our laws have provided for the public peace, and for protecting the realm against foreign and domestic violence, and which the statutes 2 Geo. III. cap. 20. &c. 9 Geo. III. cap. 42. declare is essentially necessary to the safety and prosperity of the kingdom. Blackst. Com. book i.

By the 2 Geo. III. cap. 20. all former acts relating to the raising of the militia are repealed, except in such cases as are therein specially directed to be subject to the provisions of the former acts, or any of them; particularly with regard to the city of London, the Tower Hamlets, and the Cinque Ports. Several statutes were subsequently enacted, which it is needless to recite; because by the 42 Geo. III. c. 90. the chief former acts relative to the militia are from June 26, 1802, repealed; excepting such as relate to the city of London, Tower Hamlets, the Stannaries, and the Cinque Ports. The militia raised under such acts shall be subject to this act; and all deficiencies under the former militia laws are to be supplied, and the men so raised are to serve according to this act. It is first provided by this act that the king shall appoint lieutenants for the several counties, &c. with full power to call together, arm, array, and cause to be trained and exercised such persons, once in every year; and such lieutenants shall appoint 20 or more persons, duly qualified, to be deputy-lieutenants, and shall also appoint a proper number of colonels, lieutenant-colonels, majors, and other officers, qualified to train, discipline, and command the persons to be armed and arrayed. The names and ranks of all such officers to be certified to his majesty, and subject to his approbation. Every person, appointed to be a deputy-lieutenant, shall be either in law or equity, for his own use and benefit, in possession of a freehold, copyhold, or customary estate for life, or for the life of his wife, she having a freehold, copyhold, or customary estate for her life, or for some greater estate, or of an estate for some long term of years determinable on one or more life or lives, in manors, messuages, lands, tenements, or hereditaments, in England, Wales, or the town of Berwick-upon-Tweed, of the yearly value of 200*l.* or shall be heir apparent of some person in like manner possessed to the yearly value of 400*l.*; a colonel, to the yearly value of 1000*l.* or heir apparent to the yearly value of 2000*l.*; a lieutenant-colonel, to the yearly value of 600*l.* or heir apparent to the yearly value of 1200*l.*; a major, to the yearly value of 400*l.* or heir apparent to the yearly value of 800*l.*; a captain, to the yearly value of 200*l.* or heir apparent to the yearly value of 400*l.* or he shall be a younger son of some person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 600*l.*; a lieutenant, to the yearly value of 50*l.* or personal estate alone to the amount of 1000*l.* or real and personal estate together of the value of 2000*l.* or he shall be son of some person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 100*l.* or of a personal estate alone to the amount of 200*l.* or real and personal estate together to the value of 3000*l.*; an ensign, to the yearly value of 20*l.* or a personal estate alone to the amount of 500*l.* or real and personal estate together of the value of 1000*l.* or he shall be son of some person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 50*l.* or who shall be, or at the time of his death was, possessed of a personal estate alone to the amount of 1000*l.* or of real and personal estate together of the value of 1500*l.*; one moiety of which said estates, excepting of lieutenants and ensigns, shall be situate within the respective counties, ridings, or places, in which they shall be appointed to serve.

Provided, that the immediate reversion or remainder of and in manors, messuages, lands, tenements, or hereditaments, which are leased for one, two, or three lives, or for any term of years determinable on the death of one, two, or three lives, on reserved rents, and which are to the lessees of the clear yearly value of 300*l.* shall be deemed equal to an estate herein before described, of the yearly value of 100*l.* and so in proportion. f. 10.

Also, a person, either at law or equity, for his own use and benefit, in possession of an estate for a term originally granted for 20 years or more, of an annual value (over and above all rents and charges payable in respect of the same) equal to the annual value of such an estate as is required for the qualification of a deputy-lieutenant and commissioned officer respectively, and situate as aforesaid, shall be deemed sufficiently qualified.

In the counties of Cumberland, Huntingdon, Monmouth, Westmorland, and Rutland, and in every county and place in Wales, the qualifications shall be as follow, and of the like estates as before mentioned:

A deputy-lieutenant's shall be of the yearly value of 150*l.* or he shall be heir apparent to an estate of the yearly value of 300*l.*; a colonel's of the yearly value of 600*l.* or he shall be heir apparent to the yearly value of 1200*l.*; a lieutenant-colonel's or major commandant's shall be of the yearly value of 400*l.* or he shall be heir apparent to the yearly value of 800*l.*; a major's shall be of the yearly value of 200*l.* or he shall be heir apparent to the yearly value of 400*l.*; a captain's shall be of the yearly value of 150*l.* or he shall be son of a person who shall be, or at the time of his death was, possessed of a like estate of the yearly value of 300*l.*; a lieutenant's shall be of the yearly value of 30*l.* or a personal estate alone to the amount of 600*l.* or real and personal together

gether of the value of 1200*l.* or he ſhall be the ſon of a perſon who ſhall be, or at the time of his death was, poſſeſſed of a like eſtate of the yearly value of 60*l.* or a perſonal eſtate alone to the amount of 1200*l.* or a real and perſonal eſtate together of the value of 2400*l.*; an enſign's, of the yearly value of 20*l.* or a perſonal eſtate alone to the amount of 300*l.* or real and perſonal together of the value of 600*l.* or he ſhall be the ſon of a perſon who ſhall be, or at the time of his death was, poſſeſſed of a like eſtate of the yearly value of 30*l* or of perſonal eſtate alone to the amount of 600*l.* or real and perſonal together of the value of 1200*l.*; of all which reſpective eſtates (except thoſe for the qualifications of lieutenants and enſigns), one moiety ſhall be within the reſpective counties or places in which ſuch officers ſhall be reſpectively appointed to ſerve.

In the iſle of Ely, a deputy-lieutenant's ſhall be of the yearly value of 150*l.* or he ſhall be heir apparent to the yearly value of 300*l.*; a captain's ſhall be of the yearly value of 100*l.* or he ſhall be heir apparent to the yearly value of 200*l.* or he ſhall be a younger ſon of ſome perſon who ſhall be, or at the time of his death was, poſſeſſed of a like eſtate of the yearly value of 300*l.*; a lieutenant's ſhall be of the yearly value of 30*l.* or perſonal eſtate to the amount of 600*l.* or he ſhall be ſon of ſome perſon who ſhall be, or at the time of his death was, poſſeſſed of a like eſtate of the yearly value of 60*l.* or perſonal eſtate to the amount of 1200*l.*; an enſign's ſhall be of the yearly value of 20*l.* or perſonal eſtate to the amount of 300*l.* or he ſhall be the ſon of ſome perſon who ſhall be, or at the time of his death was, poſſeſſed of a like eſtate of the yearly value of 30*l.* or perſonal eſtate to the amount of 600*l.*; one-half of all which eſtates (except thoſe for the qualifications of lieutenants and enſigns), ſhall be ſituate or ariſing within the ſaid iſle of Ely, or ſome other part of the county of Cambridge.

In all cities or towns which are counties within themſelves, and have heretofore uſed to raiſe and train a ſeparate militia within their reſpective liberties, and which are united with and made part of any county for the purpoſes of raiſing the militia only, the lieutenant thereof, or, where no lieutenant, the chief magiſtrate, ſhall appoint the deputy-lieutenants, and alſo the officers of the militia, whoſe number and rank ſhall be proportionable to the number of men which ſuch city or town ſhall raiſe as their quota towards the militia of the county to which they are united for ſuch purpoſes; and all powers and proviſions made with reſpect to counties at large ſhall take place in the ſaid cities or towns. And the qualification for a deputy-lieutenant ſhall be 150*l.* a-year as aforeſaid, or a perſonal eſtate alone, or real and perſonal eſtate together, to the amount or value of 3000*l.* Field officer 300*l.* or perſonal eſtate alone, or real and perſonal together, to the value of 5000*l.* Captain 150*l.* a-year, or perſonal eſtate alone, or real and perſonal together, to the value of 2500*l.* Lieutenant 30*l.* a-year, or perſonal eſtate of 750*l.* Enſign 20*l.* a-year, or perſonal eſtate of 400*l.* One-half of all which real eſtates (except thoſe for the qualification of lieutenants and enſigns) ſhall be within ſuch city or town, or within the county to which ſuch city or town is united for the purpoſes aforeſaid. ſ. 9.

The whole number of private men to be raiſed, excluſive of certain places that are excepted, is 39,572; in various proportions for the ſeveral counties. Such numbers ſhall continue to be the reſpective quotas, until the 25th day of June, 1805, and from thence until other quotas ſhall be appointed by his majeſty's privy council; and the reſpective quotas that ſhall at or after the expiration of the ſaid firſt mentioned period, and alſo from time to time at or after the expiration of every ſucceſſive ten years after ſuch period, be ſo appointed by the privy council, ſhall from the appointment thereof continue until other quotas ſhall be appointed under this act.

By this act proviſion is made for a "Supplementary Militia;" for in caſe of invaſion, or imminent danger of it, and alſo in caſe of rebellion, the king may (the occaſion being firſt communicated to parliament if ſitting, or declared in council, and notified by proclamation, if there be no parliament ſitting) by his proclamation order and direct, in addition to the number of militia-men aforeſaid required to be raiſed under this act, any number of men not exceeding one-half of the aggregate number of the militia to be raiſed and enrolled. Theſe men ſhall, in purſuance of ſuch proclamation, be raiſed by the lieutenants and deputy-lieutenants. His majeſty may alſo, by proclamation, diſembody the ſupplementary militia; and the privates ſo diſembodied, or thoſe enrolled and not embodied, ſhall remain liable to ſerve and to ſupply all vacancies. The lieutenants and deputy-lieutenants ſhall hold meetings, and iſſue precepts for returning liſts, and ſettling of liſts, for proportioning the numbers in the ſeveral hundreds, &c., and the deputy-lieutenants ſhall cauſe the number appointed to ſerve to be choſen by ballot out of the liſt returned for every pariſh, &c. Pariſhes are allowed to offer volunteers without ballotting.

The perſons exempted from ſerving in the militia, or providing ſubſtitutes, are peers of this realm; commiſſioned officers in his majeſty's other forces, or in any of his caſtles or forts; non-commiſſioned officers and private men ſerving in any of his majeſty's other forces; commiſſioned officers ſerving, or who have ſerved four years in the militia; members of either of the univerſities; clergymen; licenſed teachers of any ſeparate congregations; conſtables, or other ſuch peace officers; articled clerks, apprentices, ſeamen or ſeafaring men; perſons muſtering and doing duty in any of his majeſty's dock-yards; perſons free of the company of watermen of the river Thames; perſons employed and muſtered at the Tower of London, Woolwich Warren, the ſeveral gun-wharfs at Portſmouth, Chatham, Sheerneſs, and Plymouth, or at the powder mills, magazines, or the houſes under the direction of the board of ordnance; and poor men who have more than one child born in wedlock. And by 43 Geo. III. c. 123. a perſon ſerving or having found a ſubſtitute in the army of reſerve; and by 44 Geo. III. c. 54. any effective volunteer. Perſons ballotted, that refuſe to ſerve or provide a ſubſtitute, ſhall forfeit 10*l.* which, by 43 Geo. III. c. 50. is increaſed to 15*l.* and at the expiration of five years, be liable to ſerve again, in perſon or by ſubſtitute. Thoſe who have ſerved are to be returned home in due time, ſo that they may reach the county to which they belong, if abſent from it, by the expiration of their term; unleſs they ſhall conſent to ſerve again. The enliſting of perſons enrolled to ſerve in the militia, for ſervice in his majeſty's other forces, ſhall be deemed null and void. The militia are required to be trained and exerciſed by regiment or battalion, once in a year for twenty-eight days together (43 Geo. III. c. 19.): and the penalty of not appearing, or deſerting, is the immediate payment of 20*l.* or impriſonment for ſix months, or till the money is paid. In caſe of actual invaſion, or immediate danger of it, or rebellion in this kingdom, his majeſty, communicating the occaſion to parliament, if ſitting, or declared in council, and notified by proclamation, if parliament be not ſitting, may order the militia to be embodied, put under the command of general officers, and led to any part of the kingdom, but not to go out of it; and they ſhall be ſubject to the acts againſt mutiny

and

and desertion. And any person not appearing, shall be liable to be apprehended and punished as a deserter; and if any person shall harbour or conceal any such militia man, he shall for every such offence forfeit 100*l.* From the date of his majesty's command for drawing out the militia into actual service, the officers and privates shall be entitled to the same pay as those of other infantry. Officers of the militia, during the time of service, are exempted from the office of sheriff, nor does the acceptance of a commission in the militia vacate the seat of any member returned to serve in parliament (42 Geo. III. c. 90.): and private men from highway duty, from parish offices, and serving in his majesty's other forces by sea or land. Militia men, when sick, are entitled to relief; and their destitute families to a weekly allowance out of the poor rates of the parish, &c. to which they belong. If they are maimed or wounded in actual service, they are entitled to the benefit of Chelsea-hospital: they may set up trades in any part of the kingdom.

As the militia of the city of London are now raised and regulated under and by virtue of the 36 G. 3. c. 92. and 39 G. 3. c. 82: And as the militia of the Tower Hamlets are now raised and regulated by the 37 G. 3. c. 75. and c. 25. and the same are thereby respectively made subject to certain provisions in the 26 G. 3. c. 107. by this act repealed; it is enacted, that, from and after the passing of this act, all and every the clauses, provisions, powers, authorities, punishments, bounties, penalties, forfeitures, matters, and things in this act contained, in relation to any persons, acts, matters, and things as to which the 26 G. 3. c. 107. or any of the clauses or provisions thereof, were in force or applicable as to the said respective militias, shall, from and after the passing of this act, be applied, practised, and put in full force as to all such persons, matters, and things, as far as the same can be applied, and are not contrary to any of the provisions of the said respective acts, or any or either of them: But nothing in this act contained shall be construed to extend to repeal any of the provisions of the said acts, or either of them, other than such as are in and by the said acts made subject to the rules and regulations of the 26 G. 3. c. 107.

Nothing in this act shall extend to the tinners in Devon and Cornwall; but the lord warden of the stannaries for the time being in pursuance of his majesty's commission in that behalf, and such as he shall commissionate and authorize under him, shall use the like powers, and array, assess, arm, muster, and exercise the said tinners as has been heretofore used, and according to the ancient privileges and customs of the stannaries.

The lord warden of the cinque ports, two ancient towns and their members, and in his absence his lieutenant or lieutenants, shall put in execution within the same all the powers and authorities granted by this act, in like manner as his majesty's lieutenants of counties and their deputy-lieutenants may do; and may keep up and continue the usual number of soldiers in the said ports, towns, and members, unless he or they find cause to lessen the same; and the militia of the said ports, towns, and members, shall remain separate from the militia of the several counties within which the said ports, towns, and members are situate; and the said warden, or his lieutenant or lieutenants, shall, in pursuance of orders from his majesty, in the manner prescribed by the 13 and 14 Car. 2. notwithstanding one or more months pay advanced be not reimbursed, raise and draw out the soldiers into actual service, and cause the persons charged as by the said act to provide their soldiers with pay in hand, not exceeding one month's pay, in such manner as if all the pay advanced and provided had been reimbursed; and shall use the like powers, and array, assess, and arm, muster and exercise the said soldiers, and make assessments, and issue warrants for the assessments made or to be made for raising any trophy money, and for defraying the necessary charges of trophies, and other incident expences of the militia of the said ports, towns, and members, as hath been heretofore used, and according to their ancient privileges and customs; any thing in the said act or this act to the contrary notwithstanding.

By 48 Geo. III. c. 111. and subsequent acts, a particular species of force is ordered to be raised under the name of the "Local Militia;" the provisions of which act regulate the mode of raising the same kind of force in the Cinque Ports, Stannaries, and some other privileged places. The number of men ballotted and enrolled under this denomination in any county, division, or part of any county, shall not exceed such number as will, including the effective yeomanry and volunteers then serving in such county, &c. exclusive of supernumeraries above the establishment of such corps, serving without pay, who shall have been enrolled therein after the 1st of April 1808, amount to six times the respective original quota or proportion of militia of such county, &c. under the 42 Geo. III. c. 90. The deficiencies in effective yeomanry and volunteers in any county, &c. shall be supplied from time to time by local militia men; so that the number in the whole of the local militia under this act, and effective yeomanry and volunteers, shall be equal to six times the amount of such quota or proportion. Volunteers are allowed to enter, whether any order be given for supplying deficiencies or not, until the local militia be completed; and such volunteers shall receive two guineas each, payable on their respective enrolment. By 49 Geo. III. c. 40, this is repealed, except as to members of volunteer corps. Volunteers transferring themselves into the local militia, are not liable to serve in the regular militia, in consequence of any former ballot. The men to be raised under the act 48 Geo. III. c. 111. shall be ballotted out of the persons between the ages of 18 and 30 returned in the lists now existing, or hereafter returned, amended or corrected for the raising of the militia; and his majesty may direct the making out of new lists; and no person ballotted to serve in the local militia shall be allowed to find any substitute, or be entitled to any bounty or half bounty. Persons ballotted are to take a prescribed oath, and then to be enrolled to serve in the local militia of such county as a private local militia man for the space of four years. Persons unable to serve from illness or bodily infirmity shall be excused; and persons exempted are licensed teachers of any congregation in holy orders, or pretended holy orders, and not carrying on any other trade, or exercising any other occupation for his livelihood, except that of a school-master; such medical men actually practising as physicians, surgeons, or apothecaries; no person mustered, trained, or doing duty, or employed in his majesty's service in the Tower of London, the royal arsenal at Woolwich, or at any gun wharfs, or at any powder mills, powder magazines, or other storehouses belonging to his majesty, under the direction of the board of ordnance, shall be liable to be ballotted for the local militia, so long as they respectively continue within any of the aforesaid descriptions; and every person who shall have served, or is now serving in person in the additional military force, raised under an act passed in the forty-third year of the reign of his present majesty, or who shall have been ballotted, and have provided any substitute, or shall have paid any fine for not serving or finding a substitute in such additional force, shall be exempt from ballot and service in the local militia, in like manner, and for the same period, as such person was or is exempt from ballot and service in the regular militia

during

during the continuance of the said act of the forty-third year aforesaid; any thing in any act or acts of parliament to the contrary notwithstanding.

No person having served in the regular militia or such additional force, or provided any substitute, or paid any fine for not serving, or finding any substitute in the regular militia or such additional force as aforesaid, shall be entitled to exemption from being ballotted under this act, for any longer period than four years after the expiration of his period of service, if he shall have served in person, or six years from the period of any such substitute being enrolled, or four years after having paid any such fine.

And no articled clerk or apprentice, nor any poor man who has less than three children born in wedlock, nor any person under the height of five feet four inches, who shall be of the height of five feet two inches, or upwards, shall by reason thereof, respectively be exempt under this act, notwithstanding they may, by reason thereof, respectively be exempt from the militia.

Provided that nothing in this act contained shall extend to authorize any apprentice ballotted under this act, to enlist in the army, navy, marines, or regular militia, or to enter as a volunteer in the local militia, without the consent of his master; provided also, that no ballot, enrolment, and service under this act, shall make void or in any manner affect any indenture of apprenticeship or contract of service between any master or servant, notwithstanding any covenant or agreement in any such indenture or contract, and no service under this act of any apprentice or servant shall be deemed to be an absence from service, or a breach of any covenant or agreement as to any service or absence from service in any indenture of apprenticeship or contract of service.

And every person claiming to be exempted from service under this act, upon payment of the fine of twenty pounds, or ten pounds, instead of thirty pounds, shall sign a declaration that the amount of his income does not exceed two hundred pounds or one hundred pounds as aforesaid, as the case may be, and shall deliver the same to the deputy-lieutenants before whom he shall appear to claim such exemption, or produce a certificate to the like effect, allowed by any commissioners under any act relating to the rates and duties arising on property, &c. or to any allowances made on any such rates and duties, within twelve months previous to the production of such certificate. Quakers, or united brethren, on production of certain certificates, shall not be enrolled, and may be adjudged to pay a proportion of the fines on persons ballotted, and not appearing. Persons serving in the local militia are entitled to the same exemptions as volunteers, and having served four years, are not liable to be ballotted for the regular militia for two years. Local militia officers shall not be exempt from serving the office of sheriff.

His majesty may order the local militia to be called out yearly to be trained; but they are not to be trained for more than 28 days in a year, nor to be ordered to march for that purpose further than some adjoining county. In case of invasion, or appearance of an enemy in force upon the coast of any part of the united kingdom, his majesty may order the local militia to be embodied and marched to any part of Great Britain, and continue there, so embodied, for any period not exceeding six weeks after the enemy shall have been prevented or repelled, or driven from the coast, or after any rebellion or insurrection shall have been suppressed. Lord lieutenants, &c. may call out the local militia for the suppression of riots, and those who do not appear are subject to certain penalties; but when so called out, they are not to be kept assembled for more than 14 days in one year. Local militia assembled in time of war are subjected to the mutiny act. Every person enrolled to serve in the local militia shall, upon being assembled for training and exercise, be entitled to receive one guinea for the first year of his service, and 10*s.* 6*d.* for each succeeding year; and a further sum of one guinea in case such person shall be embodied under any order of council or proclamation. The local militia, when not drawn out and embodied, shall be entitled to the same pay, clothing and allowances, as the regular militia are when not embodied; and when drawn out and embodied, shall be entitled to the same pay, clothing, and allowances, for themselves and families, as his majesty's other militia forces when drawn out and embodied. Local militia men may enlist in the army, navy, or marines, or regular militia of the same county; and their vacancies shall be supplied as other vacancies. No person shall enlist a local militia man during the period of training, on penalty of 20*l.* Every county, hundred, or parish, is subject to a fine of 15*l.* for each man deficient at a certain period, but it shall be entitled to a return of part, for every man enrolled within a certain time.

MILITUM CURIA. See CURIA.

MILITUM *Expensis levandis.* See EXPENSIS.

MILIUM, in *Botany*, an ancient name for a sort of corn or grass, remarkable for the abundance of its seeds; hence Festus, against whom we certainly can have no appeal, derives it from *mille*, a thousand. The plant of the Romans however was either a *Holcus*, or the *Panicum miliaceum*, or both; and our Linnæan genus has obtained this appellation from its resemblance in seed to those.—Linn. Gen. 33. Schreb. 47. Willd. Sp. Pl. v. 1. 358. Mart. Mill. Dict. v. 3. Sm. Fl. Brit. 75. Prodr. Fl. Græc. Sibth. v. 1. 44. Ait. Hort. Kew. ed 2. v. 1. 147. Juss. 29. Leers. 18. t. 8. f. 7.—Class and order, *Triandria Digynia.* Nat. Ord. *Gramina.*

Gen. Ch. *Cal.* Glume of two, nearly equal, ovate, tumid, pointed valves, inclosing a single flower. *Cor.* of two ovate valves, less than the calyx, permanent, finally cartilaginous, enfolding the seed; one of them smaller than the other. Nectary of two ovate, obtuse leaflets, tumid at the base. *Stam.* Filaments three, capillary, short; anthers oblong, versatile. *Pist.* Germen roundish; styles two, capillary; stigmas tufted. *Peric.* none, except the hardened and polished corolla, which closely invests the solitary roundish *seed.*

Eff. Ch. Calyx of two valves, single-flowered, tumid. Seed invested with the permanent hardened two-valved corolla.

1. M. *capense.* Cape Millet-grass. Linn. Mant. 185. Willd. n. 1.—"Panicle capillary. Calyx pointed. Corolla with a terminal curved awn."—Native of the Cape of Good Hope. *Stems* four inches high, smooth and slender. *Leaves* narrow, clothed underneath with scattered hairs, and bearded at the top of their sheath. *Panicle* spreading every way; the flower-stalks finer than a hair. *Calyx* of two ovate, slightly swelling, pointed valves, of nearly equal length. *Seed* the length of the calyx. *Awn* terminal, curved, longer than the flower." Such is the description Linnæus gives of this grass, which no botanist has ever been able to ascertain. Nothing in his herbarium bears this name, and yet there can be no doubt of his having described a specimen of his own. In writing the second *Mantissa*, he was often negligent about marking the plants he described. There is found in his genus *Avena*, confounded with the Spanish *A Loeflingiana*, from which it is very distinct, a Cape specimen, which answers precisely to his description of the *Milium* in question, except that the calyx generally contains

tains two florets, each with the twisted awn of an *Avena*. This however is as good a *Milium* as *M. paradoxum*, and we have no scruple in considering it as what Linnæus intended. The hairy sheaths and backs of the *leaves*, as well as the bearded *stipula*, are remarkable. The *corolla* is externally hairy. We cannot refer this grass to any in Thunberg's *Prodromus*.

2. M. *punctatum*. Dotted Millet-grass. Linn. Sp. Pl. 91. Amoen. Acad. v. 5. 392. Swartz. Obs. 37. Brown. Prod. Nov. Holl. v. 1. 188.—Panicle of alternate, linear, simple clusters. Lower flowers in pairs; upper solitary. Flower-stalks jointed. Outer valve of the corolla with a short awn. Native of Jamaica, in moist meadows. *Swartz*. Gathered by Mr. R. Brown near Port Jackson, as well as in the tropical part of New Holland; by Dr. Rottler at Madras. A pale upright grass, with the habit of a *Leersia*, or a *Paspalum*. *Stem* from one to two feet high, simple, round, jointed, smooth, leafy. *Leaves* broadish, striated, slightly roughish, with long smooth sheaths. *Panicle* a span long, erect, close, with hairy stalks. *Flowers* crowded, turned one way, ovate, acute, hairy. *Corolla* included, elliptical; its outer valve tipped, as Dr. Swartz and Mr. Brown observe, with a short rough awn. A purple stain, like a dark dot, under each flower, seems to have given rise to the specific name.

3. M. *lendigerum*. Panick Millet-grass. Linn. Sp. Pl. 91. Schreb. Gram. v. 2. 14. t. 23. f. 3. Engl. Bot. t. 1107. Fl. Græc. Sibth. v. 1. 49. t. 65. (Agrostis australis; Linn. Mant. 30. A. ventricosa; Gouan. Hort. 39. t. 1. f. 2. Knapp. t. 25. Gramen paniceum serotinum, spicâ laxâ pyramidali; Moris. v. 3. 189. n. 12. *Herb. Bobart.*)—Panicle close, somewhat spiked. Corolla awned, fringed.—Native of fields in the south of Europe, where water has stagnated; rather rare in England. Dr. Sibthorp found it on the sandy sea-shore of Asia Minor. It is annual, and flowers in the latter part of summer. The tufted fibrous *roots* produce many *stems*, from ten to twenty inches high. *Leaves* rough, with slightly swelling sheaths, and long, white, torn stipulas. *Panicle* pale, erect, acute, from one to four inches long, of innumerable crowded *flowers*; the base of their *calyx* tumid, smooth and polished. The permanent hardened *corolla*, which invests the seed, makes this species more certainly a *Milium*, than an *Agrostis*.

4. M. *compressum*. Compressed Millet-grass. Swartz. Ind. Occ. 183. Willd. n. 4.—Spikes two or three together, linear, on a very long stalk. Flowers alternate, close-pressed, awnless. Stem compressed, jointed in the middle.—Common in barren, rather alpine pastures in Jamaica; communicated by Dr. Swartz. *Roots* white, thread-shaped, perennial. *Stems* a foot high, or more, smooth, compressed quite flat, with a downy joint about the middle. *Leaves* long, linear, smooth, finely striated, radical; except one from the joint in the middle of the stem, which is broader, with a very long compressed sheath, bearded at its orifice. *Flower-stalks* from four to eight, from the sheath of the stem-leaf, about a foot long, thread-shaped, smooth, each bearing a pair of terminal, erect, linear, slender *spikes*, about two inches long, sometimes accompanied by a third at some distance, all together resembling some of the genus *Panicum*. The *common stalk* of each is zigzag and acutely angular. *Flowers* small, elliptic-oblong. *Calyx* ribbed, brownish, minutely fringed.

5. M. *digitatum*. Fingered Millet-grass. Swartz. Ind. Occ. 181. Willd. n. 5—Spikes finger-like, about four together, nearly sessile. Florets acute, awnless, close-pressed, in pairs, directed one way. Leaves with cartilaginous serratures.—Gathered by Dr. Swartz in barren pastures, in the south of Jamaica. This appears to be still more akin to *Panicum* than the last, having sometimes a minute third valve to its *calyx*. The *stem* is a foot high, simple, slender, upright, smooth. *Leaves* lanceolate, short, striated, with compressed bearded sheaths. *Spikes* terminal, slender, somewhat spreading, two inches long, purplish. *Flowers* in pairs, rather unequal, on serrated stalks.

6. M. *paniceum*. Panick-like Millet-grass. Swartz. Ind. Occ. 179. Willd. n. 6.—Spikes rather finger-like, alternate, spreading, thread shaped. Flowers triangular, awnless, stalked, in pairs, turned one way.—In dry sandy ground, in the southern part of Jamaica. *Swartz*. *Stem* a foot high, simple, slender, erect, roundish, smooth. *Leaves* linear, smooth; their sheaths hairy at the orifice. *Spikes* three or four, slender, alternate, but near together, at the top of a long slender stalk, spreading. *Flowers* minute. *Glumes* of the *calyx* somewhat fringed; the outer one convex; the inner flat. *Corolla* the shape and size of the calyx, smooth, brown and shining, finally blackish, containing the very small seed.

7. M. *effusum*. Spreading Millet-grass. Linn. Sp. Pl. 90. Curt. Lond. fasc. 4. t. 12. Engl. Bot. t. 1106. Knapp. t. 19. Willd. n. 7. (Gramen miliaceum; Ger. em. 6.)—Flowers loosely panicled, awnless. Glumes elliptical, pointless, sheaths of the leaves smooth.—Native of shady groves, where the ground is rather moist, throughout Europe, flowering in June or July. *Root* creeping, perennial. *Stems* erect, two or three feet high, leafy, smooth. *Leaves* light green, broad, flat, roughish at the edges; their sheaths smooth and naked, crowned by an oblong membranous *stipula*. *Panicle* erect, lax and widely spreading, composed of several alternate fascicles of variously branched capillary flower-stalks. *Flowers* solitary, pale whitish-green, elliptical, rather acute, but not pointed; their *calyx-glumes* even, finely ribbed, generally quite smooth, sometimes minutely roughish, never hairy nor fringed. *Corolla* at length horny, quite smooth and finely polished.

8. M. *confertum*. Close Millet-grass. Linn. Sp. Pl. ed. 1. 61. ed. 2. 90. Willd. n. 8. (Gramen paniculatum alpinum latifolium, paniculâ miliaceâ sparsâ; Scheuchz. Agrost. 134.)—Flowers closely panicled, awnless. Glumes elliptical, pointless. Sheaths of the leaves smooth.—Native of Switzerland. Haller asserts under his n. 1525. Hist. v. 2. 243, that this proved, on an inspection of Scheuchzer's specimen, a mere variety of the last. We know it not.

9. M. *arundinaceum*. Reed-like Millet-grass. Sm. Prodr. Fl. Græc. Sibth. v. 1. 45. Fl. Græc. t. 66. (Agrostis miliacea; Linn. Sp. Pl. 91. Willd. Sp. Pl. v. 1. 363.)—Flowers loosely panicled. Corolla awned, smooth. Calyx taper-pointed. Sheaths of the leaves smooth. Stipula very short, abrupt.—Native of Siberia, Spain, Portugal, Zante, and the neighbourhood of Athens. The modern inhabitants of Zante call it γεγλαγη. The *root* is perennial, tufted, with tortuous, downy, strong fibres. *Stems* numerous, two feet high, round, smooth, most knotty in their lower part. *Leaves* spreading, acute, roughish, with close smooth sheaths. *Panicle* rather turned to one side, slender, constructed much like that of *M. effusum*, but the *flowers* are only half as large, with ovate, tumid, long-pointed *calyx-glumes*, often reddish. *Corolla* ovate, the outer valve tipped with a rough awn, twice its own length. *Seed* coated with the hardened *corolla*, which makes the plant a true *Milium*, its resemblance to *Agrostis Spica-venti*, hinted by Linnæus, chiefly regarding its first aspect, and disappearing on a close examination.

10. M. *angulosum*. Little Angular-husked Millet-grass.—Flowers closely panicled, awnless. Glumes ovate, acute, strongly

ftrongly ribbed and furrowed. Sheaths of the leaves hairy.—Gathered in the Sandwich iflands, by Archibald Menzies, efq. This has the habit of the three preceding, but is diftinguifhed by the hairinefs of the backs of the *leaves*, and of their fheaths. The joints of the *ftem* are denfely bearded. *Panicle* rather clofe, at leaft in the dried fpecimen, drooping. *Flowers* fmaller than even thofe of *M. arundinaceum*, their glumes ftrongly ribbed, bluntly pointed, deftitute of awns, and of all hairinefs.

11. M. *fetofum*. Briftly-hufked Millet-grafs.—Flowers clofely panicled, pointed, awnlefs. Calyx fringed with long hairs. Sheaths of the leaves hairy.—Gathered in the Sandwich iflands, likewife by Mr. Menzies. *Root* of ftrong fmooth fibres, probably annual. *Stem* branched, a foot or more in height, with numerous joints, under each of which it is rough and hairy. *Leaves* and their fheaths very hairy, light green. *Panicle* much like the laft, but fhorter. *Glumes* of the calyx ftrongly furrowed, with a fhort but ftout point, fcarcely amounting to an awn; they are remarkably fringed, with a few fine long fpreading hairs, at each fide. *Corolla* elliptical, awnlefs, very fmooth, fmaller than the calyx.

12. M. *tenellum*. Small Tumid Millet-grafs. Cavan. Ic. v. 3. 37. t. 274. f. 1.—Panicle ovate, denfe, awnlefs. Calyx-glumes inflated, almoft hemifpherical, very fmooth. Sheaths of the leaves fwelling, ribbed, fmooth.—Gathered in fandy ground in Spain by the late Abbé Cavanilles, to whom we are obliged for a fpecimen. This is a little annual vernal grafs, in habit, fize and colour like *Aira caryophyllea*, along with which it grows. The *ftems* branch from the bottom, and are clothed with a few fhort, narrow, involute *leaves*, with long, inflated, ribbed, purplifh, fmooth fheaths. The upper part of each *branch* is naked, round, fmooth, rigid, purple, bearing an ovate, denfe, glittering *panicle*, an inch long. *Glumes* of the calyx rugofe at the keel, ovate, almoft hemifpherical, concave, enclofing the much fmaller *corolla*, which latter we have not feen in an advanced ftate, fo as to judge of the generic character. The afpect of the glumes of the *calyx* is that of a *Briza*.

13. M. *globofum*. Globofe Millet-grafs. Thunb. Jap. 49. Willd. n. 9.—Panicle fpreading, awnlefs; its partial ftalks annulated. Calyx-glumes ovate, obtufe. Sheaths of the leaves fringed.—Gathered by Thunberg in Japan. *Stem* fimple, erect, a foot high or more. *Leaves* lanceolate, ftriated, rough, bordered, fpreading, hardly a finger's length; their fheaths fringed at the edges and orifice. *Panicle* fomewhat ovate, fpreading; its ftalks capillary, zigzag, marked with a yellow ring near the top. *Calyx* ovate, obtufe, awnlefs, fmooth, brownifh-green. *Thunb.*

14. M. *paradoxum*. Black-feeded Millet-grafs. Linn. Sp. Pl. 90. Scop. Carn. t. 1. Schreb. Gram. v. 2. 50. t. 28. f. 2. Hoft. Gram. Auftr. v. 3. 16. t. 23. Willd. n. 10.—Panicle fpreading. Calyx ovate, taper-pointed, ribbed. Corolla long-awned, fmooth. Sheaths of the leaves fmooth. Stipula elongated, acute.—Native of the fouth of France, and of Carniola. A tall, flender, reed-like grafs, with narrow, fmooth, rather glaucous, taper-pointed *leaves*, whofe fheaths are clofe and fmooth, and their *ftipula* long, white, thin, membranous, acute, torn at the point. *Panicle* with folitary, fpreading, flender, compound branches. *Flowers* very large in proportion to all the foregoing, one-third of an inch in length. *Calyx-glumes* purplifh, ovate, concave, keeled and ribbed, with a long membranous point. *Corolla* half the length of the calyx, finally becoming black, hard and polifhed, its outer valve tipped with a long rough awn.

15. M. *racemofum*. Racemofe Millet-grafs.—Flowers in a fimple upright clufter. Calyx elliptical, acute, ribbed. Corolla long-awned, hairy. Leaves lanceolate, with fmooth fheaths.—Sent by the Rev. Dr. Muhlenberg from Lancafter in Pennfylvania. The *ftem* is flender, leafy, fmooth. *Leaves* lanceolate, flat, taper-pointed, half an inch broad. *Flowers* the fize of the laft, four or five, in a flender, erect, perfectly fimple *clufter*, with finely downy ftalks. *Calyx* many-ribbed, green. *Corolla* at length brown, clothed with a few fine hairs, and not much polifhed, bearing a long rough awn.

16. M. *cærulefcens*. Bluifh Millet-grafs. Desfont. Atlant. v. 1. 66. t. 12. Sm. Prodr. Fl. Græc. Sibth. v. 1. 45.—Panicle fpreading. Calyx ovate, taper-pointed. Corolla fmooth, with a flight awn fhorter than the calyx. Sheaths of the leaves fmooth. Stipula elongated, jagged.—Gathered by Desfontaines in the fiffures of rocks on mount Atlas, and by Dr. Sibthorp abundantly in the Greek ifles.—This has nearly the appearance of *M. paradoxum*, efpecially the *panicle*, but the *leaves* are more narrow and glaucous, the *corolla* fmaller, with only a fhort deciduous awn.

17. M. *villofum*. Shaggy-flowered Millet-grafs. Swartz. Prodr. 24. Obf. 383. Willd. n. 11. (Andropogon infulare; Linn. Sp. Pl. 1480. (Gramen avenaceum, paniculâ minùs fparfâ, glumis albâ fericeâ lanugine obductis; Sloane Jam. v. 1. 43. t. 14. f. 2.)—Panicle flightly fpreading, awnlefs. Calyx clothed with long hairs. Sheaths of the leaves fmooth.—Native of Jamaica and the Brazils. The *leaves* are lanceolate, roughifh. *Panicle* of very numerous angular branches. *Flowers* about half the fize of the laft, remarkable for the long filky hairs that clothe the *calyx*. *Awns* none. This fpecies feems rather to belong to the genus *Saccharum*. We know nothing of its *corolla*.

18. M. *ramofum*. Branching Millet-grafs. Retz. Obf. fafc. 6. 22. Willd. n. 12.—Stem branched, compreffed, decumbent. Flowers clofely panicled, hairy, ufually in pairs. Sheaths of the leaves fmooth.—Native of the Eaft Indies. *Stems* leafy, downy at the joints. *Leaves* linear, narrow, quite fmooth as well as their fheaths. *Panicles* feveral, on long ftalks, from the fheaths of the upper leaves, each a fpan long, clofe, fimply branched. *Flower-ftalks* thickened and fringed at the top, with a black ring under each flower. *Calyx* lanceolate, hairy. *Corolla* fmooth, polifhed, hard, the outer valve with a rigid point fhorter than the calyx. *Stigmas* long, feathery, brown. The nature of the *corolla* being confidered, the doubts of the accurate Retzius, whether this grafs fhould be reckoned a *Milium* or *Agroftis*, vanifh.

Milium *Arundinaceum*, a name by which fome authors call the lachrymæ Jobi, or Job's tears.

Milium *Indicum*, a name by which fome authors call the maize, or Indian wheat.

MILK, in *Rural Economy*, and *Animal Chemiftry*, is a white opaque fluid, fecreted by a certain organ exifting in all lactiferous animals. This fecreting apparatus is differently fituated in different animals. In women it is placed in the anterior part of the breaft: in the cow, the mare, the ewe, and fome others, it is fituated in the lower part of the abdomen. While in the fow, the bitch, and feveral other quadrupeds, it is arranged through the whole courfe of the abdomen. The glandular fubftance which conftitutes this organ is called the mamma: that projecting portion of the mamma, from whence the milk iffues, being called the papilla, or nipple. The mammæ are more or lefs in number in different animals, according to their number of young, fome having as many as ten, others but one. In the human fubject the mammæ are two, each having one nipple. In the cow but one mamma, with four nipples. This organ in all animals appears deftined to furnifh their

young

young with nouriſhment, till their own digeſtive organs are capable of performing their functions. Hence we find the period of lactation in animals to commence when they bring forth their young. This ſhews a ſtrong connection between the ſecretion of milk, and the uterine action. All this may eaſily take place from the great connection between thoſe branches of nerves which are beſtowed upon the mammæ and the uterus.

At the age of puberty, the ſame nervous connection which may induce the uterine action, may, at the ſame time, be alſo beſtowed upon the mammæ, cauſing them to be enlarged. During pregnancy, the nervous influence which is expended in forming the ſecretions for the growth of the fœtus, is, after delivery, transferred to the mammæ to produce lactation. Since ſecretion is dependent upon nervous influence, all ſubſtances moderately ſtimulating muſt facilitate the formation of milk. Some have ſuppoſed that the mammary artery is too ſmall to furniſh the quantity of milk which is furniſhed during lactation, and have thought that the chyle has been the principal ſource of this fluid. Fourcroy is of opinion, that the more ſubſtantial part of milk only is ſecreted from the blood, and that the aqueous part is furniſhed from the lymphatic veſſels. What renders this idea plauſible is, the very different ſtates in which we find cows' milk from different kinds of food.

Milk, as an article of food, and its products, are of ſuch importance in domeſtic economy, as to render all the improvements in its production and management particularly valuable. Since the milk of the cow is the moſt abundant and in general uſe, we ſhall confine the analyſis of this ſubſtance to cows' milk.

Milk, when drawn from the cow, is of a yellowiſh-white colour, and is the moſt yellow in the beginning of the period of lactation. The viſcidity of milk is ſomething greater than that of water. In this ſtate it has a peculiar but pleaſant odour, which becomes leſs by expoſure to the air, but returns when expoſed to heat. Its taſte is peculiar, rather agreeable, and ſomewhat ſaccharine. This, however, varies in different animals, and in the ſame animal, from particular kinds of food. Cabbage and turnips, when eaten by cows, give each their peculiar flavour to milk; and if they eat the ſmalleſt quantity of wild garlic, the milk and butter become perceptibly flavoured with its peculiar odour.

The ſpecific gravity of milk, on the average, is about 1.035, water being 1. According to Briſſon, whoſe authority on this phyſical property of bodies ſtands high, the following are the ſpecific gravities of the milk of different animals.

Women's milk - - -	1.0203
Cows' - - - -	1.0324
Goats' - - - -	1.0341
Mares' - - - -	1.0346
Aſſes' - - -	1.0355
Ewes' - - - -	1.0409

The ſpecific gravity of cows' milk varies from ſeveral cauſes. It is greateſt at the beginning of lactation. It is the leaſt when the milk appears the thinneſt, or when it is the moſt aqueous. Cows feeding on grains, which is the caſe frequently in large towns, give poor milk, of little ſpecific gravity.

When milk is expoſed, in a cold ſituation more eſpecially, it ſoon becomes covered with a ſubſtance, of greater viſcidity than the milk, of a yellow colour, and having an unctuous feel. This is called cream. The quantity of this ſtratum bears different proportions to the milk under different circumſtances. The milk now loſes ſome of its viſcidity, and becomes of a bluer colour. In this ſtate it is known by the name of ſkimmed milk. See DAIRYING.

When milk is expoſed to heat, it firſt ſwells, and boils, it is ſaid, at the temperature 199° of Fahrenheit. The ſurface ſoon becomes covered with a pellicle, which, if removed, is ſoon ſucceeded by another. This effect would take place till the reſiduum would become of an aqueous appearance, and incapable of furniſhing any pellicle. This ſubſtance formed on the ſurface, is found no longer to poſſeſs the properties of milk, but is a peculiar ſubſtance called caſeous matter, and is the ſame which conſtitutes the ſolid matter called cheeſe.

When milk is very ſlowly evaporated it forms a kind of thick extract of milk, which is called *franchipane*. This being mixed with ſugar, almonds, and orange flowers, conſtitutes a ſort of ſweetmeat or cuſtard.

When milk is diſtilled, a liquor comes over which has the odour of milk, but does not poſſeſs any other of its properties. It ſoon becomes putrid, depoſiting white flakes. If the heat be raiſed and continued, the thick part of the milk undergoes the deſtructive diſtillation. Empyreumatic oil, zoonic acid, and ammonia, are formed, with the diſengagement of carburetted hydrogen gas. After the proceſs, a voluminous coal is found in the ſtill.

When milk has been expoſed for ſeveral days in a temperature from 60° to 70°, it becomes a thick coagulum, ſo ſolid as not to be capable of pouring. During this change it is found that an acid has been formed which has ſeparated the milk into two portions, the one the coagulable part, called curd, or caſeous matter; the other the ſerous part, called whey. This change is alſo effected by other acids and by alcohol. The mineral acids are not proper for this purpoſe, becauſe they re-diſſolve the curd. Hence the vegetable acids are ſaid to produce more curd than the mineral acids. The ſubſtance generally employed by cheeſe-makers to ſeparate the curd, is a ſmall portion of the inner coat of the ſtomach of the calf, which is ſalted, dried, and kept for that purpoſe.

By a particular management milk may be made to undergo the vinous fermentation, by which a quantity of alcohol is formed. It will be eaſy to infer, however, that this change is occaſioned by the ſaccharine matter which it contains.

The Tartars have long been in the practice of making a vinous liquor, from which they diſtilled a ſpecies of brandy. This they procure from mares' milk, which is known to contain more ſugar than that of the cow. By expoſing it in large open veſſels, the fermentation takes place. The maſs being large, no doubt contributes to this change. A quantity both of the lactic and acetic acids are formed at the ſame time, which are ſeparated from the vinous ſpirit by repeated diſtillations. The curdy or caſeous part of milk above alluded to, is preſſed into molds for cheeſe. (See DAIRYING and CHEESE.) Although acids ſeparate the curd when added in ſmall quantity, yet when in conſiderable quantity, the curd becomes re-diſſolved. It is remarkable, that dilute vegetable acids ſeparate the curd without re-diſſolving it, while theſe acids, concentrated, diſſolve the ſame. The curd is, on the contrary, eaſily diſſolved by the dilute mineral acids, but not by theſe acids in their concentrated ſtate.

Many other ſubſtances coagulate milk, ſuch as alcohol, molaſſes, gelatine, and all aſtringent vegetables. The effect is ſuppoſed to ariſe from the affinity of the coagulating ſubſtance to water, the curd, which is principally albumen, having very little affinity for the ſame. The alkalies diſſolve curd with great facility, owing to their great affinity

affinity for that substance. If ammonia be added to milk which has curdled, it will restore it to the appearance of milk, by dissolving the curd. Lime has also the power of dissolving curd. If quick-lime be boiled with curd into the form of pulp, it forms a most powerful cement. A similar property may perhaps belong to barytes and strontian.

When curd is freed from cream, kneaded, and pressed to expel the liquid matter, it becomes very hard with time, assumes a degree of transparency, and possesses many of the properties of dried coagulated albumen. Exposed to heat, it softens and becomes glutinous. The heat being continued, it becomes brown, exhales fumes, which contain ammonia; and lastly, inflames, leaving a dense coal behind.

The dried curd does not change by exposure to the air, but if it contains moisture, it soon putrifies, giving a disagreeable fetid odour. This change would take place in cheese, if it were not for muriat of soda, which also acts as a seasoning. It is likely that certain proportions of nitre, muriat of soda, and sugar, would make an agreeable seasoning for cheese, and would be a better preservative than salt alone.

If curd remains in cold water for a length of time, its properties become changed; it becomes fat, unctuous, and soft, having, at the same time, a fetid smell. It is, doubtless, to a certain degree of this change that we may attribute what is called the ripening of cheeses, by laying them in a damp place, and turning them from time to time. The cheeses absorb a quantity of water, and gain much weight. Their bulk is increased, and the interior is much altered, and is said to be ripe or mellow. Instead of allowing the cheese to absorb water, it is not uncommon for epicures to saturate it with port wine, or strong ale.

The white colour of milk, after the cream has been separated, is owing to the curd. This substance, in numerous minute particles in a state of coagulation, constitutes its white opaque appearance, since the whey, after the last portions of curd and cream have been separated, becomes transparent and limpid.

The clear liquor last mentioned is what we shall now examine under the name of whey, or the serum of milk. It differs from the whey of dairies, since the latter always contains a portion of oily matter, as well as some unseparated curd. To get the serum or whey sufficiently pure for chemical examination, a small quantity of fresh membrane of the calf's stomach must be employed to coagulate the milk. This will be more effectually done by boiling them together till the change takes place. Previous, however, to this, the milk must be perfectly freed from its cream, by placing it in a cool situation, and skimming it frequently. When the curd is separated, first strain it through a coarse cloth; afterwards filter it through unsized writing paper.

In this state the whey is limpid, and of a greenish-yellow colour. It has a peculiar sweetish smell when hot, which it loses on cooling. Its taste is rather sweet, and not disagreeable. When exposed to a boiling heat, a whitish scum rises to the surface, the liquid becoming rather turbid. If it be boiled a little while, and then set to cool, that which rendered it turbid falls, leaving the liquor clear, and almost as colourless as water. This residuum last named, is a small portion of curd which remained in the whey. The clear liquor thus obtained is of less specific gravity than milk, being 1.0193. By slow evaporation, it affords crystals of a substance much resembling sugar, but much less soluble. This has been called sugar of milk. Near the end of the evaporation, crystals of the muriats of potash and soda are deposited, and some phosphat of lime.

The circumstance of muriat of potash being afforded in this analysis, is strongly in favour of the idea that milk is not wholly secreted from the blood, since potash is never found in that fluid. The sugar of milk is in the form of crystals of a brown-yellow colour. These, when purified by several successive solutions and evaporations, become white, of a prismatic shape, or rather parallelopipedons.

This substance is soluble in about four parts of boiling water, and twelve of cold. It is manufactured and sold in Switzerland, under the name of salt or sugar of milk.

When treated with nitric acid, with a view to obtain oxalic acid, a smaller portion of this acid is obtained than from the same weight of sugar. Scheele, however, who first made this experiment, found that a quantity of white powder was separated, which he found to be a peculiar acid, and which he denominated the acid of sugar of milk. This has been altered into *Saclactic acid*, which see. Fourcroy found that the same acid was afforded by treating gum arabic with nitric acid. On this account he called it the mucous acid. It was from this latter fact that this sagacious chemist inferred that sugar of milk was a substance of a middle nature between gum and sugar. It is the opinion of Deyeux and Parmentier, that sugar of milk consists of sugar combined with the saclactic acid.

The mother water, from which the sugar of milk is obtained, is of a brown colour, and of a thick gluey consistence, which, on cooling, assumes the appearance of animal jelly. If this be diluted and slowly evaporated a second time, an additional quantity of the muriat of potash is separated in crystals, and also of phosphats of soda and lime. The presence of phosphat of lime in the serum of milk, may be detected both by precipitating its acid and its base. If oxalat of ammonia be poured into the clear whey, a precipitate of oxalat of lime is formed. On the other hand, when nitrat of lead or nitrat of mercury is employed as a test, the phosphats of lead and mercury are precipitated. The great quantity of phosphat of lime in milk, in order to supply ossifying matter, so essential to young animals, is a remarkable provision of nature.

The remaining part of the whey chiefly consists of gelatine. If when whey has been evaporated to the consistency of syrup, a quantity of alcohol be poured upon it, a flaky precipitate is formed, consisting of gelatine and sugar of milk. The gelatine may be separated by tannin. Thus we see that whey consists of sugar of milk, gelatine, muriats of potash and soda, and phosphats of lime and soda, with a certain quantity of water. It is also said that whey contains sulphat of potash, and the phosphats of iron and magnesia.

Whey is exceedingly liable to turn sour. The acid which is formed, was thought by Scheele to be what he termed the lactic acid; the same which is formed when milk coagulates spontaneously. It is, however, now found to be the acetic acid, arising from the acetous fermentation which has succeeded the vinous; the latter being induced by the saccharine matter which the milk contains.

Having given the analysis of milk deprived of cream, or the oily part, we shall now give some account of the latter, which is also denominated the butyraceous part of milk.

Cream, the mode of separating which we have already given, gradually thickens by exposure to the air, and ultimately becomes a soft unctuous solid, called cream cheese. When cream is exposed to its boiling heat, and oil soon appears upon its surface, the rest of the cream consists of caseous matter and whey. This oil, by the operation of churning, is converted into a solid fatty substance, so well known under the name of butter. See BUTTER and DAIRYING.

If milk, when newly taken from the cow, be agitated for ſome time, the oily matter becomes concrete, and is diſperſed through the fluid in ſmall grains. Theſe being collected, conſtitute butter. It was formerly thought, that the agitation of the milk merely collected and preſſed the ſmall particles of butter together. It is now believed that the butter does not exiſt ready formed in the milk, but in a ſtate of oil, which requires to combine with oxygen before it can become hard. This idea is rendered plauſible by ſeveral circumſtances. The more acid the cream has become before churning, the ſooner butter is formed. It has alſo been aſcertained, that the preſence of freſh atmoſpheric air facilitates the formation of butter. The frequent inſtances which occur in practice, of not getting butter at any rate, may doubtleſs be traced to the want of a ſupply of oxygen. This may be a hint of ſome importance in the management of large dairies.

When butter has been obtained from cream, the liquid remaining conſiſts of milk, containing minute particles of butter. If cream has been kept till it ſhall have become ſour, the curd becomes precipitated. In this caſe it becomes of a thicker conſiſtence. This is known by the name of butter-milk.

Butter, prepared as above, is of a yellow colour, and more yellow as the cream has been kept longer. Its taſte is very unlike any other fatty ſubſtance, and extremely agreeable. This, however, is not always the caſe, ſince its flavour is ſometimes altered by the food of the cow. When it has been expoſed to the air for a certain time, it acquires a rancid taſte. Its flavour ſometimes becomes changed, and rendered diſagreeable, by a portion of the butter-milk which has not been waſhed out of it.

Butter, when newly made, fuſes in about 99° of Fahrenheit. Its ſpecific gravity is about .96, water being 1. When it is expoſed to the heat of boiling water in a glaſs tube, a portion of curd and whey is ſeparated from it. By this proceſs the butter becomes almoſt tranſparent; but it will be found to have loſt much of its agreeable taſte. Hence it would ſeem, that its flavour either depends upon the ſmall portion of ſerum and curd, which is always a conſtituent of butter, or that its aroma is expelled by the heat. Butter is not changed by a heat which merely fuſes it.

When butter is diſtilled from a ſmall glaſs retort, ſome drops of water firſt appear, and the greater part of the butter comes over. This is accompanied by a diſagreeable ſmell, and an inflammable gas. A ſmall quantity of coaly matter is left at the bottom of the retort, which contains phoſphat of lime. By repeated diſtillation, the oily ſubſtance which comes over becomes lighter and more volatile. This is probably owing to the ſeparation of carbon. If the retort be large, the oxygen, being more abundant, cauſes the formation of more water with the hydrogen from the butter. Another portion of the hydrogen and a portion of carbon combine with the oxygen, forming ſebacic acid.

Butter combines with moſt of the ſubſtances which combine with fat, ſuch as ſulphur, phoſphorus, the alkalies, and ſeveral metallic oxyds.

By collecting the different parts which have been given, we ſhall find the conſtituents of cows' milk as follows: curd; ſerum or whey, which conſiſts of water; gelatine; ſugar of milk, or mucaceous ſaccharine matter; muriats of ſoda and potaſh; ſulphat of potaſh, and the phoſphats of lime; magneſia and iron; butter, conſiſting of an oxygenated oil, combined with a little ſerum and caſeous matter.

In caſes where the milk of animals is taken away periodically by milking, as in the cow, the ſupply is continued, and hence the great value of that animal, in particular, to man, who is indebted to her for three of the moſt uſeful articles of food, milk, butter, and cheeſe. But in reſpect to the quality of milk, it differs conſiderably in different circumſtances and ſituations, and from the manner in which the cows are fed and managed. In order to have an abundant ſupply, it is neceſſary to have recourſe to conſtant plentiful feeding of the animals with rich luxuriant green food of different ſorts, given in a proper varied manner, as well as other kinds of food. In comparing the qualities of the milk of different cows, the time in which they have been in milk ſhould be fully conſidered, as the milk, ſoon after calving, is always much thinner than it is afterwards. The properties of milk, ſo far as they regard the dairy, and the management of it in reſpect to the making of butter and cheeſe, will be taken notice of in another place. In caſes where the mother is loſt, or the young animal is too feeble to have recourſe to her teats, milk with ſugar, gruel, and a ſmall quantity of ſpice, is ſometimes given as a means of ſupport. See DAIRYING, LACTOMETER, BUTTER, and CHEESE.

The milk of different animals differs conſiderably.

Women's milk is much thinner than cows' milk; is of a bluer colour, and contains more ſaccharine matter. It does not afford butter till ſome time after delivery, although it contains ſome oily matter. It contains leſs curd than the milk of the cow. The milk of women is liable to greater changes from diſeaſe than any other. Spaſms, which are not uncommon to thoſe who ſuckle, ſo change the milk, as to be unpleaſant and unwholeſome to the infant. It is obſerved by Deyeux and Parmentier, that when the milk is drawn from the breaſt at ſhort intervals, it is conſtantly watery and poor, and is of but little ſervice to the infant. They therefore recommend, that the intervals of ſuckling ſhould be as great as poſſible, without inconvenience to the infant or the nurſe.

The milk of the aſs is alſo different from cows' milk: it contains more ſaccharine matter, and, like women's milk, is thinner than that of the cow. There is nothing in this milk more than in others, to warrant the medical qualities which ſome aſcribe to it.

Aſſes' milk is ſaid to be a great beautifier and preſerver of the ſkin. Poppæa, wife of the emperor Nero, uſed it for that purpoſe; having four or five hundred aſſes conſtantly in her retinue, to furniſh her every morning with a freſh bath. The receipt for making what is called artificial aſſes' milk is as follows:

℞ limac. terreſt. contus. xviii. Raſur. C. Cervi, Hordei perlati, Rad. eryngii, ſing. unc. i. aquæ puræ lib. vi. coque leni igne in vaſe ſigulino vitriato ad lib. iii; dein cola et adde ſyrupi balſamici ſeſcunciam. Capiat æger mane et veſperi quotidie unc. iv. hujus liquoris miſtas cum lactis vaccin. recentis p. æ. Med. Tranſ. vol. ii. p. 341.

Goats' milk is ſomething thicker, and appears richer than even the cows' milk. It has a peculiar aroma, which, from the black goat, is ſo ſtrong as to be diſagreeable. It affords butter and cheeſe: the former is of a whiter colour than that from the cow, and is ſaid to keep longer.

Ewes' milk has the appearance of cows' milk. It affords a much larger quantity of cream, forming a ſoft and very fuſible butter. Its caſeous matter is very ſoft and unctuous, and is ſometimes mixed with that from the cow, to give it a rich appearance.

Mares' milk is the next to women's milk in quantity of ſaccharine matter: it affords little cream; and does not eaſily coagulate.

coagulate. It is from the quantity of fugar contained in this milk, that it affords alcohol by fermentation.

Milk, in the *Wine Trade.* The coopers know very well the ufe of fkimmed milk, which makes an innocent and efficacious forcing for the fining down of all white wines, aracks, and fmall fpirits; but is by no means to be ufed for red wines, becaufe it difcharges their colour. Thus, if a few quarts of well-fkimmed milk be put to a hogfhead of red wine, it will foon precipitate the greater part of the colour, and leave the whole nearly white; and this is of known ufe in the turning red wines, when pricked, into white; in which a fmall degree of acidity is not fo much perceived.

Milk is, from this quality of difcharging colour from wines, of ufe alfo to the wine-coopers, for the whitening of wines that have acquired a brown colour from the cafk, or from having been haftily boiled before fermenting; for the addition of a little fkimmed milk in thefe cafes precipitates the brown colour, and leaves the wines almoft limpid, or of what they call a water whitenefs, which is much coveted abroad in wines as well as in brandies.

Milk, in *Geography,* a river of Jamaica, which runs into the fea, four miles N.W. of Maccaree bay.

Milk *Cove,* a creek of Ireland, on the S.E. fide of the entrance into Rofs bay, near Gully Head.

Milk *Haven,* a fmall harbour of Ireland, in the county of Sligo, S. of Donegal bay.

Milk *River,* a river of Canada, which runs into lake Erie, N. lat. 42° 28′. W. long. 82° 22′.

MILKING, the means or operation of drawing the milk from the cow or other animal. The proper milking of cows is a matter of much confequence to the cow and dairy farmer. And it has been obferved, that more care is neceffary in this bufinefs than is generally fuppofed, in order to obtain the largeft poffible quantity of milk. "On the phyfiological principle of the fecretions of animals being increafed in proportion as the fecreted fluid is more frequently withdrawn, it has been, it is faid, recommended to have recourfe to more frequent milkings in order to augment the quantity of that fluid in cows. And there can be little doubt but that by accuftoming the fecretory organs to a more frequent fecretion, fuch a habit may be eftablifhed in them as will afford a large proportion of milk in a given time. But in order to effect this in the moft perfect manner, it will be neceffary to have the cows highly fed, and to obferve the greateft regularity and exactnefs in the periods of milking, and to be careful that every drop of milk is drawn away each time, as without due regard in thefe refpects the defired effect will not be produced. This is fully fhewn to be the cafe by the few experiments that have been inftituted with the view of deciding the matter; as while the cows were confuming the more juicy fpring food, there appears to have been an increafe in the quantity of milk both by three and four milkings in the day; but in the autumnal feafon there feems to have been rather a decreafe under the fame circumftances." But "in order to afcertain the advantages to be obtained in this way with accuracy, the following experiments were made by Mr. Marco, and the refults ftated in the twelfth volume of the Annals of Agriculture to be thefe:

		Pints.
1789—May 21,	Firft meal - -	$9\frac{1}{2}$

But it is evident, that "fuch trials, to afford any fatisfactory conclufions, fhould have been continued for a much greater length of time, being varied confiderably in the times of milking, and nicely compared with the nature and quantity of the food employed; as it is only by afcertaining how much depends upon the fimple operation of taking away the milk, and how much upon the quality and proportion of food that is taken in, that the queftion can be fairly decided.

decided. The deterioration of the animal should also be considered. It is not to be supposed that merely increasing the number of milkings for a few days can have much influence in altering the state of the secretion in the animals. Some, with the intention of increasing the quantity of milk, have recommended milking, when the cows are fully fed in the summer season, three times in the course of the day at equal distances, as the convenience of the business will admit as the most proper. Early in the morning, about the middle of the day, and in the evening before it is too late. The exact proportion of increase in the milk that may be produced in this way over that of milking in the morning and evening only, which is the usual mode, has not, that we know of, been ascertained with any degree of accuracy; but some suppose that it may approach to nearly one-half of the whole, while others contend that it cannot be any thing near so much. If a third were gained, by such means, it would amply repay the cow-keeper for his additional trouble and expence."

With respect to "the method of milking adopted by cow-farmers in most cases, it is only to have their milking performed twice in the course of twenty-four hours. In such cases the most proper times would seem to be about seven o'clock in the morning, and five in the afternoon; but in the neighbourhood of London, according to the Report of Middlesex, and in other large towns, it is the practice to have this work performed from four to half-past six in the morning, and from half-past one to three in the afternoon. It is, therefore, probable, that more frequent milking in the business of cow-farming, especially when conducted upon an extensive scale, would not only be inconvenient but impracticable. In such cases it is supposed, that all that can be done is, perhaps, that of having the operation executed with as much care as possible, in respect to the whole of the milk being taken away each time, and by persons who are careful and perfectly accustomed to the work. Where this is neglected, much loss may be sustained not only in the immediate produce of the milk, but in the cows becoming much more quickly dry, as well as their being more subject to affections of the udder. The best advice is, to have the business performed in an expeditious manner, in regard to the whole of the animals, and with the utmost attention in respect to cleanness. A sufficient number of persons should of course be employed in proportion to that of the cows. An expert milker is capable of performing the operation on from six to seven or eight cows in the course of an hour." It is proper that the number of milkers employed should constantly be such as to have the business performed in about the course of an hour at the farthest. See Dairy, and Dairying.

Milking *Pail*, in *Rural Economy*, the vessel made use of for containing the milk as it is drawn from the cow. These pails are made of wood, and sometimes hooped with iron at the bottom. They are made of different sizes, and should be kept well seasoned by frequent scalding.

MILL, John, in *Biography*, a learned English divine and biblical critic, was born at Shapp, in Westmorland, about the year 1645. He was entered of Queen's college, Oxford, where he took his degrees in arts, and of which college he afterwards became a fellow and eminent tutor. As soon as he entered into holy orders he distinguished himself by his pulpit talents, and was much followed as an eloquent preacher. He published one of his sermons preached at St. Martin's-in-the-Fields about the year 1676, intended to shew that there was no sort of foundation for the worship of the Virgin Mary, and at this period the bishop of Exeter appointed Mr. Mill one of his chaplains, and gave him a prebend in his cathedral church. In 1680 he took his degree of B.D., and in the following year was presented by his college to the rectory of Blechingdon, in Oxfordshire, at the same time proceeded doctor in divinity, and was nominated chaplain in ordinary to king Charles II. Dr. Mill had been some years employed in preparing for the press his valuable edition of the "New Testament," which is now as rare as it is excellent. This great work he undertook by the advice and with the encouragement of Dr. Fell, bishop of Oxford, at whose expence it was to be printed. At an early stage of the business the liberal-minded prelate died, and his executors being unwilling to proceed with the work, Dr. Mill, with a noble spirit, refunded to them the sums of money which his departed friend had advanced, and determined to complete it at his own risk. To this work, which cannot fail to transmit his name with distinguished honour to posterity, he devoted the thirty last years of his life, with the most patient assiduity, as well as scrupulous care, and he had the satisfaction of seeing his useful labours brought to a close, and the fruits of them presented to the world. In 1685, Dr. Mill was elected principal of St. Edmund's hall, Oxford, which preferment was the more acceptable, as it gave him an honourable settlement in the university, and enabled him to prosecute his design to the utmost advantage. In 1704 he was, by the interest of Dr. Sharp, archbishop of York, presented with a prebendary of Canterbury. His work was published in 1707, an event which he did not survive more than a fortnight, being carried off by an apoplectic stroke in the sixty-third year of his age. Of his great learning his work gives ample proofs: it is founded upon, and is an improvement of, Robert Stephens' elegant folio edition, published at Paris in the year 1550, which has in the inner margin the collation of sixteen manuscripts, and of bishop Fell's neat and accurate edition, published at Oxford in 1675. To the various readings of the former, Dr. Mill added those of sixteen MSS. out of the English Polyglot bible. He also collated himself all the valuable MSS. in England, and procured collations of the most esteemed ones at Rome, Paris, Vienna, and other places, as well as of the ancient translations of the New Testament. This edition of the New Testament was reprinted at Rotterdam in 1710, in folio, by the learned Kuster, who augmented it with the collation of twelve new MSS. It was also reprinted at Leipsic in 1723. Dr. Mill's labours gave very general satisfaction to the learned of this country, and to biblical scholars every where; but there were some few who doubted if it might not tend to unhinge the minds of people, by countenancing the notion that the text was precarious, as the author had collected thirty thousand various readings. On this account Dr. Whitby made it the subject of an attack, which was ably answered by Mr. Whiston, and still more fully by Dr. Bentley, in the thirty-second section of his "Remarks" upon it, under the assumed title of "Phileleutherus Lipsiensis." Biog. Brit.

MILL *Iſlands*, four ſmall iſlands in Hudſon's bay. N. lat. 64° 30'. W. long. 78° 30' to 79° 40'.

MILL, in propriety, denotes a machine for grinding corn, &c. but, in a more general ſignification, is applied to all machines whoſe action depends on a circular motion.

Of theſe there are ſeveral kinds, according to the various methods of applying the moving power; as water-mills, wind-mills, mills worked by horſes, &c.

Few people are ignorant, that corn is ground by two mill-ſtones, placed one above the other, without touching.

The lower mill-ſtone is immoveable, but the upper one turns upon a ſpindle. The oppoſite ſurfaces of the two ſtones, which act to grind the corn, are not plane or flat; but the upper one is hollow, and the under one ſwells up; each of them being of a conic figure, whoſe axis indeed is very ſhort, in proportion to the diameter of its baſe; for the upper one being ſix feet in diameter, is hollowed but about one inch at its centre; and the lower one riſes but about three-fourths of an inch. Theſe two mill-ſtones come nearer and nearer towards their circumference, whereby the corn that falls from the hopper has room to inſinuate between them as far as two-thirds of the radius, which is the place where it begins to be ground, and where it makes the greateſt reſiſtance that it is capable of; the ſpace between the two ſtones being in that place about but two-thirds or three-fourths of the thickneſs of a grain of corn. But as the millers have the liberty of raiſing or ſinking the upper ſtone a little, they can proportion its diſtance from the lower one, according as they would have the flour finer or coarſer.

In order to cut and grind the corn, both the upper and under mill-ſtones have channels or furrows cut in them, proceeding obliquely from the centre towards the circumference. And theſe furrows are each cut perpendicularly on one ſide, and obliquely on the other, into the ſtone; which gives each furrow a ſharp edge, and in the two ſtones, they come, as it were, againſt one another, like the edges of a pair of ſciſſars; and ſo cut the corn to make it grind the eaſier, when it falls upon the places between the furrows. Theſe are cut the ſame way in both ſtones when they lie upon their backs, which makes them run croſs-ways to each other, when the upper ſtone is inverted by turning its furrowed ſurface towards that of the lower. For if the furrows of both ſtones lay the ſame way, a great deal of the corn would be drove onward in the lower furrows, and ſo come out from between the ſtones without ever being cut. When the furrows become blunt and ſhallow by wearing, the running ſtone muſt be taken up, and both ſtones new dreſt with a chiſſel and hammer. But, by this repeated operation, their thickneſſes, and conſequently their weight, diminiſh; and it is obſerved, that when they come to have but three-quarters, or half of the thickneſs which they had when new, they produce but three-quarters or half the flour which they yielded at the beginning.

The circular motion of the upper mill-ſtone brings the corn out of the hopper by jerks, and cauſes it to recede from the centre towards the circumference, where, being quite reduced to flour, it is thrown out of the mill, by the centrifugal force of the ſtone, through a hole provided on purpoſe.

The diameter of common mill-ſtones, according to Dr. Deſaguliers, is from five to ſeven feet, and their thickneſs, twelve, fifteen, or eighteen inches: they laſt thirty-five or forty years, and when they have been long uſed, ſo that their thickneſs is conſiderably diminiſhed, they are cut anew, to give their ſurface a contrary figure to what they had before: ſo that the upper mill-ſtone is made the lower.

In water-mills, the momentum of the water is the moving power, and the attrition of the two ſtones in grinding is the force to be overcome. Of theſe there are two kinds, *viz.* thoſe where the force of the water is applied above the wheel, and thoſe where it is applied below the wheel; the former being called over-ſhot, and the latter under-ſhot mills: and to theſe we may add a breaſt-mill, where the water ſtrikes againſt the middle of the wheel.

In a common breaſt-mill, where the fall of water may be about ten feet, A A, (*Plate* XXIII. *Mechanics*, *fig.* 1.) is the great wheel, which is generally about ſeventeen or eighteen feet diameter, from *a* the outermoſt edge of any float board, to *b*, that of its oppoſite float. To this wheel the water is conveyed through a channel, and falling upon the wheel, turns it round. On the axis B B, of this wheel, and within the mill-houſe, is a wheel D, about eight or nine feet diameter, having ſixty-one cogs, which turn a trundle E, containing ten upright ſtaves or rounds; and when this is the number of cogs and rounds, the trundle will make $6\frac{1}{10}$ revolutions for one revolution of the wheel. The reaſon of adding an odd cog, called the hunting cog, to the wheel, is this; that, as every cog comes to the trundle, it may take the next ſtaff or round behind the one which it took in the former revolution, and thus it will wear all the parts of the cogs and rounds which work upon one another equally, and to equal diſtances from one another in a little time; and make a true uniform motion throughout the whole work. The trundle is fixed upon an iron axis called the ſpindle, the lower end of which turns in a braſs foot, fixed at F, in the horizontal beam S T, called the bridge-tree; and the upper part of the ſpindle turns in a wooden buſh fixed into the lower mill-ſtone, which lies upon beams in the floor Y Y. The top part of the ſpindle above the buſh is ſquare, and goes into a ſquare hole in a ſtrong iron croſs, *a b c d*, (*fig.* 2.) called the rynd; under which, and cloſe to the buſh, is a round piece of thick leather upon the ſpindle, which it turns round at the ſame time as it does the rynd. The rynd is let into grooves in the under ſurface of the running mill-ſtone G, (*fig.* 1.) and ſo turns it round in the ſame time that the trundle E is turned round by the cog-wheel D. This mill-ſtone has a large hole quite through its middle, called the eye of the ſtone, through which the middle part of the rynd and upper end of the ſpindle may be ſeen; whilſt the four ends of the rynd lie hid below the ſtone in their grooves.

The end T of the bridge-tree T S (which ſupports the upper mill-ſtone G upon the ſpindle) is fixed into a hole in the wall; and the end S is let into a beam Q R called the brayer, whoſe end R remains fixed in a mortiſe: and its other end Q hangs by a ſtrong iron rod P, which goes through the floor Y Y, and has a ſcrew-nut on its top at O; by the turning of which nut, the end Q of the brayer is raiſed or depreſſed at pleaſure; and, conſequently, the bridge-tree T S and upper mill-ſtone. By this means the upper mill-ſtone may be ſet as cloſe to the under one, or raiſed as high from it, as the miller pleaſes. The nearer the mill-ſtones are to one another, the finer they grind the corn; and the more remote from one another, the coarſer.

The upper mill-ſtone G is incloſed in a round box H, which does not touch it any where; and is about an inch diſtant from its edge all around. On the top of this box ſtands a frame for holding the hopper *k k*, to which is hung the ſhoe I, by two lines faſtened to the hind-part of it, fixed upon hooks in the hopper, and by one end of the

crook-

crook-ſtring K faſtened to the fore-part of it at *i*; the other end being twiſted round the pin L. As the pin is turned one way, the ſtring draws up the ſhoe cloſer to the hopper, and ſo leſſens the aperture between them; and as the pin is turned the other way, it lets down the ſhoe, and enlarges the aperture.

If the ſhoe be drawn up quite to the hopper, no corn can fall from the hopper into the mill; if it be let a little down, ſome will fall: and the quantity will be more or leſs, according as the ſhoe is more or leſs let down. For the hopper is open at bottom, and there is a hole in the bottom of the ſhoe, not directly under the bottom of the hopper, but forwarder towards the end *i*, over the middle of the eye of the mill-ſtone.

There is a ſquare hole in the top of the ſpindle, in which is put the feeder *e* (*fig.* 2.); this feeder (as the ſpindle turns round) jogs the ſhoe three times in each revolution, and ſo cauſes the corn to run conſtantly down from the hopper, through the ſhoe, into the eye of the mill-ſtone, where it falls upon the top of the rynd, and is, by the motion of the rynd and the leather under it, thrown below the upper ſtone, and ground between it and the lower one. The violent motion of the ſtone creates a centrifugal force in the corn going round with it, by which means it gets farther and farther from the centre, as in a ſpiral, in every revolution, until it be thrown quite out; and, being then ground, it falls through a ſpout M, called the mill-eye, into the trough N. When the mill is fed too faſt, the corn bears up the ſtone, and is ground too coarſe; and beſides, it clogs the mill ſo as to make it go too ſlow. When the mill is too ſlowly fed, it goes too faſt, and the ſtones, by their attrition, are apt to ſtrike fire againſt one another. Both which inconveniencies are avoided by turning the pin L backwards or forwards, which draws up or lets down the ſhoe; and ſo regulates the feeding as the miller ſees convenient.

Sometimes, where there is a ſufficient quantity of water, the cog-wheel in *fig.* 1. turns a large trundle, on whoſe axis is fixed a horizontal wheel, with cogs all around its edge, turning two trundles at the ſame time; whoſe axis or ſpindles turn two mill-ſtones. When there is not work for them both, either may be made to lie quiet, by taking out one of the ſtaves of its trundle, and turning the vacant place towards the horizontal cog-wheel. And there may be a wheel fixed on the upper end of the great upright axle of this wheel for turning a couple of boulting-mills; and other work for drawing up the ſacks, fanning and cleaning the corn, ſharpening of tools, &c. As the water acts upon an over-ſhot mill both by impulſe and weight, ſo does it likewiſe upon a breaſt-mill, or that where the water comes upon the breaſt or middle part of the wheel: and here, though the weight of the water is not ſo great as in the over-ſhot mill, being contained in the buckets of the lower quarter only; yet the impulſe of the water is much greater, the height of the water being increaſed nearly the ſemi-diameter of the great wheel, all other things being equal. If the height of the water remain the ſame, the aperture of the penſtock muſt be enlarged to nearly twice the area, that the force may be the ſame; ſo that to produce the ſame effect, twice as much water is neceſſary for the breaſt-mill as for an over-ſhot one, every thing elſe being the ſame.

Mr. Ferguſon obſerves, that where there is but a ſmall quantity of water, and a fall great enough for the wheel to lie under it, the bucket or over-ſhot wheel is always uſed. But where there is a large body of water, with a little fall, the breaſt or float-board wheel muſt take place. As to the under-ſhot mill, it is evident there can be only the impulſe from the water; and therefore, the height of the water remaining the ſame, there muſt be a larger aperture of the penſtock for the diſcharge of a greater quantity of water in the ſame time, in order to produce the ſame effect as the over-ſhot or breaſt-mill; whence a greater expence of water will be made here than in any other mill, and can only be ſupplied for a conſtancy by a river; and where this can be had, the under-ſhot is the eaſieſt, cheapeſt, and moſt ſimple ſtructure, of which a mill is capable. Dr. Deſaguliers, having had occaſion to examine many under-ſhot and over-ſhot mills, generally found that a well made over-ſhot mill ground as much corn, in the ſame time as an under-ſhot mill with ten times leſs water; ſuppoſing the fall of water at the over-ſhot to be twenty feet, and at the under-ſhot to be about ſix or ſeven feet: and he generally obſerved, that the wheel of the over-ſhot mill was of fifteen or ſixteen feet diameter, with a head of water of four or five feet, to drive the water into the buckets with ſome momentum.

Mr. Ferguſon has given the following directions how to conſtruct water-mills, ſo as to be in the greateſt degree of perfection; and alſo a table calculated from his rules, for the ſake of thoſe mill-wrights who either cannot calculate, or do not like to take the trouble.

When the float-boards of the water-wheel move with a third part of the velocity of the water that acts upon them, the water has the greateſt power to turn the mill: and when the mill-ſtone makes about ſixty revolutions in a minute, it is found to do its work the beſt. For, when it makes but about forty or fifty, it grinds too ſlowly, and when it makes more than ſeventy, it heats the meal too much, and cuts the bran ſo ſmall, that a great part thereof mixes with the meal, and cannot be ſeparated from it by ſifting or boulting. Conſequently, the utmoſt perfection of mill-work lies in making the train ſo, as that the mill-ſtone ſhall make about ſixty turns in a minute when the water-wheel moves with a third part of the velocity of the water. To have it ſo, obſerve the following rules:

1. Meaſure the perpendicular height of the fall of water, in feet, above the middle of the aperture, where it is let out to act by impulſe againſt the float-boards on the loweſt ſide of the under-ſhot wheel.

2. Multiply this conſtant number 64.2882, by the height of the fall in feet, and extract the ſquare root of the product, which ſhall be the velocity of the water at the bottom of the fall; or the number of feet the water moves *per* ſecond.

3. Divide the velocity of the water by 3; and the quotient ſhall be the velocity of the floats of the wheel in feet *per* ſecond.

4. Divide the circumference of the wheel, in feet, by the velocity of its floats; and the quotient ſhall be the number of ſeconds in one turn or revolution of the great water-wheel on whoſe axis the cog-wheel that turns the trundle is fixed

5. Divide 60 by the number of ſeconds in a turn of the water-wheel or cog-wheel; and the quotient ſhall be the number of turns of either of theſe wheels in a minute.

6. By this number of turns divide 60 (the number of turns the mill-ſtone ought to have in a minute) and the quotient ſhall be the number of turns the mill-ſtone ought to have for one turn of the water or cog-wheel. Then,

7. As the required number of turns of the mill-ſtone in a minute is to the number of turns of the cog-wheel in a minute, ſo muſt the number of cogs in the wheel be to the number of ſtaves in the trundle on the axis of the mill-ſtone, in the neareſt whole number that can be found. By theſe rules the following table is calculated; in which the diameter of the water-wheel is ſuppoſed to be 18 feet, (and conſequently

quently its circumference 56½ feet,) and the diameter of the mill-stone to be five feet.

Perpendicular height of the fall of water in feet.	Velocity of the water in feet *per* second.	Velocity of the wheel in feet *per* second.	Number of turns of the wheel in a minute.	Required number of turns of the mill-stone for each turn of the wheel.	Nearest number of cogs and staves for that purpose. Cogs.	Stav.	Number of turns of the mill-stone for one turn of the wheel by those cogs and staves.	Number of turns of the mill-stone in a minute by these cogs and staves.

Example.—Suppose an under-shot mill is to be built where the perpendicular height of the fall of water is nine feet: it is required to find how many cogs must be in the wheel, and how many staves in the trundle, to make the mill-stone go about 60 times round in a minute, while the water-wheel-floats move with a third part of the velocity with which the water spouts against them from the aperture at the bottom of the fall.

Find 9 (the height of the fall) in the first column of the table; then against that number, in the sixth column, is 70, for the number of cogs in the wheel, and 10 for the number of staves in the trundle: and by these numbers, we find in the eighth column that the mill-stone will make $59\frac{57}{100}$ turns in a minute, which is within half a turn of 60, and near enough for the purpose; as it is not absolutely requisite that there should be just 60 without any fraction: and throughout the whole table the number of turns is not quite one more or less than 60.

The diameter of the wheel being eighteen feet, and the fall of water nine feet, the second column shews the velocity of the water at the bottom of the fall, to be $24\frac{5}{100}$ feet *per* second; the third column the velocity of the float-boards of the wheel to be $8\frac{2}{100}$ feet *per* second; the fourth column shews that the wheel will make $8\frac{51}{100}$ turns in a minute; and the sixth column shews that for the mill-stone to make exactly 60 turns in a minute, it ought to make $7\frac{5}{100}$ (or seven turns and five hundred parts of a turn) for one turn of the wheel.

Dr. Barker has invented a water-mill, that has neither wheel nor trundle: this is represented in *fig.* 3, in which A is a pipe or channel that brings water to the upright tube B. The water runs down the tube, and thence into the horizontal trunk C, and runs out through holes at *d* and *e* near the ends of the trunk on the contrary sides thereof.

The upright spindle D is fixed in the bottom of the trunk, and screwed to it below by the nut *g*; and is fixed into the trunk by two cross-bars at *f*: so that if the tube B and trunk C be turned round, the spindle D will be turned also.

The top of the spindle goes square into the rynd of the upper mill-stone H, as in common mills; and as the trunk, tube, and spindle turn round, the mill-stone is turned round thereby. The lower, or quiescent mill-stone, is represented by I; and K is the floor on which it rests, and wherein is the hole L for letting the meal run through, and fall down into a trough which may be about M. The hoop or case that goes round the mill-stone rests on the floor K, and supports the hopper, in the common way. The lower end of the spindle turns in a hole in the bridge-tree G F, which supports the mill-stone, tube, spindle, and trunk. This tree is moveable on a pin at *h*, and its other end is supported by an iron rod N fixed into it, the top of the rod going through the fixed bracket O, and having a screw-nut *o* upon it, above the bracket. By turning this nut forward or backward, the mill-stone is raised or lowered at pleasure.

Whilst the tube B is kept full of water from the pipe A, and the water continues to run out from the ends of the trunk; the upper mill-stone H, together with the trunk, tube, and spindle, turns round. But if the holes in the trunk were stopt, no motion would ensue; even though the tube and trunk were full of water. For,

If there were no hole in the trunk, the pressure of the water would be equal against all parts of its sides within. But, when the water has free egress through the holes, its pressure there is entirely removed; and the pressure against the parts of the sides which are opposite to the holes, turns the machine. See Desaguliers's Exp. Phil. vol. ii. p. 417, &c. p. 431, &c. p. 459, &c. Ferguson's Mechanics, p. 45, &c. 4to. ed. and Supp. p. 10. See also on this subject, an elaborate paper of Mr. Smeaton, containing an account of a number of experiments, in order to estimate the natural powers of water and wind to turn mills, in the Phil. Tranf. vol. li. art. 18 p. 100, &c.

The description of a mill, which we have given above in the words of the late ingenious Mr. Ferguson, is very correct. The improvements of late years, which have been made in mills for grinding corn, relate to the manner of their construction, and the proportions of the wheel-work, for giving motion to the mill-stones, by which the grinding is performed in the manner described. The late Mr. John Smeaton, F.R.S., was celebrated for his accuracy and judgment in the proportions of his mills, particularly those turned by water. We shall, under the article WATER-*Wheels*, give some account of his principles; and under this head we shall describe a steam flour-mill, which was erected from his designs, at the victualling house for the navy at Deptford, in 1781. This was before the steam-engine of Mr. Watt was brought to the perfection it has since attained; and as the old atmospheric engine was thought to be unfit for producing a rotatory motion, Mr. Smeaton erected a common steam-engine to pump up water for the supply of a large overshot water-wheel, which actuated the mill. *Fig.* 1. of *Plate* XXXIV. *Mechanics*, represents the whole mill, by a longitudinal section of the house; and *fig.* 2, another

another section, taken perpendicular to the former. The mill is double, that is, the water-wheel, A A, is situated between two buildings, only one of which is represented in *fig.* 2; and the wall, B B, of the other is one side of a house, containing exactly the same machinery as that which is delineated. Over the water-wheel two large cisterns, or troughs, C, D, are placed, communicating with each other by a large iron pipe E, *fig.* 1; and one of these troughs, C, has a pipe or trough, leading water into it, from the pump of the steam-engine supplying the water for the mill: in the other trough, D, is a shuttle *a*, which being raised up, permits the water to issue from a hole in the end of the trough, and fly forwards horizontally through a proper shute, or pentrough, into the buckets of the wheel A. The form of these buckets is shewn by *fig.* 1, a portion of the wheel being represented in section for that purpose. The buckets, which are thus filled at the top of the wheel, descend by their weight, turning the wheel round, till they come to the lowest part of the wheel; and here, by the buckets becoming inverted, the water is discharged from them, and they go up empty to the top of the wheel, where they are filled again from the trough. In this manner, one side of the wheel being always loaded by the buckets full of water, and the other side being empty, it has a constant tendency to turn round. The axis of the wheel has a large spur-wheel, E, fixed upon its extreme end, which being furnished with a double row of cogs, as shewn in *fig.* 2, communicates motion to the lanterns or trundles, F, G, one above, and the other below it: the latter, G, is fixed upon the end of an horizontal shaft H H, extending beneath the mill-stones, situated at I I and L: it actuates the upper stone of each pair, by means of crown or face-wheels K, which turn the pinions fixed at the lower ends of the respective spindle *d d*. The upper trundle, F, is fixed upon a shaft, which carries two face-wheels, *e*, *f*: the teeth of these wheels are opposite to each other, and either of them can be made to work a pinion, *g*, *fig.* 1, fixed upon the end of an axis *h*, which at the other end has a cog-wheel turning a pinion at *k*, on the end of the spindle of a machine, M, for dressing flour. This machine consists of a hollow cylinder or frame, covered with wire-cloth of different degrees of fineness; the finest being at the end A, which is the most elevated, for the axis of the cylinder is inclined in the direction of the dotted line: every one of the lengths, as it goes towards the other end, is covered with a coarser kind of wire-cloth, for sifting the flour. Within this cylinder, which is stationary, a reel is situated; its axis being exactly in the centre of the cylinder, and turned round by the pinion *k*: the rails of this reel are provided with hair brushes, which, as they revolve, brush against the interior wire surface of the cylinder. The machine is provided with a shoe or jigger, very similar to that of the mill-stones, to bring down the flour or meal through a trough, from the floor above, where it is kept after being ground: the meal, being by this means gradually fed into the cylinder, is, by the motion of the brushes on the reel, sifted or rubbed through the wire: the finest of the flour will of course go through at the upper end, but no other kind; the second through the next division, and so on till the bran falls out at the end of the cylinder, being too coarse to go through any of the wires. The cylinder is enclosed in a tight and close box M, to prevent waste by the flour flying about; and the box has partitions, which divide it into as many lengths as the cylinder has different kinds of wire. Thus each division of the box receives a different quality of flour; and spouts being fixed, which go down into the floor beneath, sacks can be filled at them without waste or inconvenience.

The pinion *g*, for turning the dressing machine, can be made to turn either way about, by engaging it with the teeth of either of the cog-wheels *e*, *f*, which acting on the opposite sides of the pinion *g*, give the means of turning it in either direction at pleasure. The pinion is of such a diameter, that it cannot be engaged with both wheels at once; and the upright lever *r*, which supports the pivot of its axis *h*, can be thrown to either side, as is shewn in *fig.* 2: for its lower end moves on a centre at the floor, and at top it is guided by a groove in a piece of wood, fixed to the ceiling, and can be fastened at either side by a pin, so as to throw the pinion in gear with either *e* or *f*. The object of this contrivance is, that when the machine, M, has for a long time been running in one direction, and its brushes become worse, or bent on one side, its motion may be reversed, to give them an equal wear on the opposite side. The wheel, *e*, has another fixed to it at the back (see *fig.* 2.), which actuates a cog-wheel N, upon the end of a roller R, having a rope wound round it, for drawing up sacks of corn or flour from one floor of the mill to another. This rope passes upwards from the roller to the roof of the building, where it passes over a pulley, and thence descends through square holes in the several floors to the ground. These holes are covered by double doors, opening upwards, so that a sack, being drawn up, opens the door, which falls down as soon as it has passed. The wheel, N, of the sack-roller can be disengaged at pleasure from the cog-wheel, *e*, which turns it; and then the rope can be unwound and run down again, to fetch up another sack. This disengagement of the wheel is effected by the same means as described of the upright lever *r*; and a line being conducted from the top of the lever, over proper pullies, into various parts of the mill, the miller can, by pulling this line, disengage the roller at pleasure, to draw up or let down a sack. A pinion and shaft, similar to *g* and *h*, *fig.* 1, may be placed on the opposite side of the wheels, *e* and *f*, to work another dressing machine at the opposite side of the mill, or what is called a bolting machine. This is rather of a different construction, being the original flour-dressing machine: it consists of a reel like the former, but without any brushes; and upon this, instead of a wire-cylinder, a cloth like a sack, cut open at the bottom, is fastened, and revolves with it; the flour, being introduced by a feeding-shoe into this, is sifted round in the revolving cloth, and the fine flour passes through. To prevent the flour accumulating at any one side of the cloth into a bag, and swinging round with it, without sifting, four rails are fixed in the machine, parallel to the axis; and if the cloth swings out by the weight of the flour within it, the cloth strikes against these rails, and the flour is thus shaken through it into the chest or case of the machine.

The lower figures of the plate contain the developement of the parts of the mill, tending to explain their construction. *Figs.* 3, 4, and 5, shew the cast-iron axis for the water-wheel; N is the cylindric shaft, and *h*, *h*, its two necks, which lay on bearings in the wall of the mill, and bear the weight: beyond these necks the axis has a square box, O O, at each end, for framing the great cog-wheels upon. The manner of attaching the arms of the great water-wheel to the shaft is this: two circular plates or flaunches, P, P, *fig.* 3, are cast upon the axis; and against each of these 12 arms, Q, Q, are bolted: they are placed against the flaunch, tending to the centre, and the spaces between them are filled up by wooden pieces, as shewn by *r*, *r*, *r*, *fig.* 4: two iron rings, R and S, are placed over the arms, and a bolt put through each arm, to attach it to the flaunch, and to the axis; the wooden pieces, *r*, *r*, are kept in their places by a wedge driven through each, within the great hoop R, and by means of these wedges the pieces, *r*, *r*, can

at

at any time be drawn up towards the centre, to hold all the arms faſt in their places.

This method of framing water-wheels was uſed with great ſucceſs by Mr. Smeaton in many inſtances, and was found to anſwer the purpoſe extremely well, being a great improvement upon the old method of mortiſing the arms into a wooden ſhaft.

Figs. 6, 7, and 8, ſhew one of the ſpindles for the mill-ſtones H and L, *fig.* 2: it is a ſtraight iron axis, *d*, formed to a pivot, *s*, at the lower end, which reſts and turns in a piece of braſs: near the upper end of the ſpindle another neck or pivot, *t*, is formed, and runs in a collar, in the centre of the nether or lower mill-ſtone, whilſt the upper one is hung upon the arms of an iron croſs T: ſee alſo *fig.* 7, fitted with a ſquare upon the top of the ſpindle. On the lower part of the ſpindle the pinion Z, which gives it motion, is fixed: it has a ſquare hole through it, fitting on the ſquare ſpindle, and iron croſſes are fixed both at top and bottom of the block of wood forming the body of the pinion: in this iron are two ſcrews (ſee *fig.* 8.), which, being ſcrewed faſt, fix the pinion firmly to the ſpindle, its weight being ſupported by a wedge, *v*, put through a hole in it; but when this wedge is withdrawn, and the ſcrews ſlackened, the pinion falls down ſo low upon the ſpindle, that its teeth are clear of the teeth of the cog-wheels *k*, *fig.* 2, and in this ſtate the ſpindle and mill-ſtone upon it will ſtand ſtill, though the mill is going. The ſpindle foot, *s*, reſts in a braſs ſocket, fixed in a lever *w*, *figs.* 1 and 2, called the bridge-tree: its fulcrum is in the ſolid wall, W, *fig.* 1, at one end, and the other reſts on the middle of a ſecond lever X, perpendicular to the former, called the brayer, one end of which has a fulcrum in the framing, *fig.* 2, and the other is ſupported by a ſcrew, which the miller turns round, to elevate or depreſs the upper ſtone, and adjuſt the diſtance between them at pleaſure, according as he wiſhes to grind finer or coarſer flour. The upper part of the mill before us is uſed as a ſtore-houſe for corn, which is drawn up in ſacks by the tackle into the roof, and there emptied into binns, or different compartments, of the upper floor: from theſe it is let down to the mill-ſtones, and ground into meal. The ſpouts from the ſtones lead the meal into ſacks, which, when full, are drawn up to the top of the houſe again, and emptied out into a flour binn, ſituated over the dreſſing machine M, which ſeparates it into various qualities for uſe.

The mills which grind for the London market uſe three dreſſing machines: the fineſt flour is that which has been paſſed through a wire-cloth of 64 *per* inch, when the meal is dreſſed the firſt time; the other part of the cylinder is coarſe wire, which ſuffers a coarſe meal, called middlings, to paſs through it; but the bran and coarſe pollard fall out at the end of the cylinder. The middlings are ground over again in a pair of mill-ſtones, which are rather dull, and become unfit for grinding corn, without dreſſing them again: then, after this ſecond grinding, the meal is dreſſed in the cloth machine, called the bolting cloth, which takes out the ſecond flour, and the pollard comes out at the end of the cloth: the bran and the pollard together are now put into the clearing-off machine, which is a coarſe wire-cylinder of the kind we have deſcribed, and by it is ſeparated into hog pollard, which is the fineſt ſort; 2d, horſe pollard; and, 3d, bran. A pair of mill-ſtones will grind five buſhels of wheat *per* hour, when in good condition; but require to be taken up and dreſſed once a week, if uſed conſtantly. This dreſſing is done by picking the ſurface of the ſtone over with the mill-pick, to cut the grooves and furrows ſharp, that they may grind and cut the corn between them.

Perſons riotouſly aſſembling and deſtroying, or maliciouſly burning, any wind-ſaw mill, wind-mill, or water-mill, &c. ſhall be guilty of felony, without benefit of clergy, by 9 Geo. III. c. 29. Proſecution to be commenced within eighteen months after the offence committed. By 41 Geo. III. c. 24. the damages occaſioned by demoliſhing any ſuch mill by perſons riotouſly aſſembled, may be ſued for and recovered in the manner provided for by 1 Geo. ſtat. 2. c. 5. reſpecting the demoliſhing of churches and other buildings. (See Riot.) By 43 Geo. III. c. 58. any perſon who ſhall maliciouſly ſet fire to any mill in the poſſeſſion of any other perſon, or of any body corporate, ſhall be guilty of felony, without benefit of clergy.

Water-mills have long been great nuiſances to agriculture, by preventing the uſe of the ſtreams on which they ſtand, in many caſes, in irrigating and flooding the adjoining lands, by which much improvement is kept back, that would otherwiſe take place. They are alſo injurious by obſtructing and damming up the water in numerous inſtances, ſo as to render it ſtagnant on the ground above. Wind and ſteam may, however, be applied as the moving powers of mills without producing any ſuch effects, and are, of courſe, the moſt proper powers to be employed.

The ancient feudal cuſtom of obliging tenants to grind at the lord's mills, is now almoſt wholly done away. Draining or lifting-mills are often extremely uſeful in diſcharging water from low flat lands in many ſituations. The moving power in theſe is commonly wind. See Mill, in *Mechanics*.

By an ancient ordinance the toll for grinding ſhall be taken either to the 20th or 24th corn; and yet, in ſome places, millers claim and take the 16th part: but Mr. Dalton ſays, that the miller ſhould take but one quart for grinding one buſhel of hard corn, and if he carry back the griſt to the owner he may take two quarts of ſuch corn, *i. e.* wheat rye, and meſlin, (wheat and rye mixed.) For malt he ſhall take half as much as for hard corn. By Holt ch. juſt. the toll of a mill muſt be regulated by cuſtom, and if the miller takes more than the cuſtom warrants, it is extortion: but if it be a new mill, the miller is not reſtrained to any certain toll. (1 L. Raym. 149.) In ſome places the tenants are bound to have their corn ground at the lord's mill. When a miller, upon information given on oath to any magiſtrate, is ſuſpected of adulterating meal or flour, the houſe, mill, &c. of ſuch miller may be entered under the authority of a warrant of a magiſtrate, at all ſeaſonable times of the day, to ſearch for diſcovery, and if ſuch adulterated meal or flour be found, it may be ſeized by the officer executing the warrant, ſeized by the magiſtrate to whom it is carried, and diſpoſed of at his diſcretion. (31 Geo. III. c. 29.) A miller who hath corn given him to grind, and who charges for that which is bad, is indictable; and he may be guilty of felony by taking away any part with an intent to ſteal it. (Hawk. c. 33.) Millers are not to be common buyers of any corn, with a view to ſell the ſame again, either in corn or meal. (Dalt. c. 122.) By 36 Geo. III. c. 85, every miller ſhall keep balances and weights according to the ſtandard of the exchequer, which may be examined by a perſon appointed for this purpoſe by 35 Geo. III. c. 102; and in default thereof the miller ſhall forfeit not exceeding 20*s.* &c &c. Millers may be required to weigh corn, and, on refuſal, ſhall forfeit not exceeding 40*s.* Millers are to deliver the whole produce of corn when ground, if required, allowing for waſte in grinding and dreſſing, and for toll when taken; and if ſuch

 corn

corn ſhall weigh leſs than the full weight, ſuch miller ſhall, for every buſhel of corn deficient in weight, forfeit not exceeding 1*s.* and alſo treble the value of ſuch deficiency. When toll is taken, it ſhall be deducted before the corn ſhall be put into the mill. No miller ſhall demand corn for toll, but in lieu thereof ſhall be entitled to payment in money, under penalty of forfeiting not exceeding 5*l.*: excepting when perſons ſhall not have money to pay for grinding, and alſo, that this ſhall not extend to mills called "Soke-mills," or ſuch ancient mills as are eſtabliſhed by cuſtom and the law of the land, which mills ſhall continue to take toll as they have been accuſtomed to do. Every miller is required to put up in his mill a table of the prices in money, or of the amount of toll or multure, on pain of forfeiting 20*s.* for every ſuch offence.

Mills, *Wind*, are, with reſpect to their working parts, little different from thoſe of water-mills; but they are turned by the force of wind gathered in their ſails.

Of theſe, ſome are called *vertical*, others *horizontal*, according to the poſition of the ſails; or, rather, according to the direction of their motion, with regard to the horizon.

For the beſt form of horizontal ſails, and alſo for determining the poſition of the axis of wind-mills, ſee Wind-*mill* and Mechanics.

Mills, *Portative* or *Hand*, are thoſe kept in motion by the hand; or elſe whoſe mill-ſtones are turned, or piſtons driven by the force of horſes or other beaſts. Thus, if the cog-wheel D, (*Plate* XXXIII. *Mechanics*, *fig.* 1.) be made about eighteen inches diameter, with thirty cogs, the trundle as ſmall in proportion, with ten ſtaves, and the mill-ſtones be each about two feet in diameter, and the whole work be put into a ſtrong frame of wood, as repreſented in the figure, the engine will be a hand-mill for grinding corn or malt in private families. And then it may be turned by a winch inſtead of the wheel A A; the mill-ſtone making three revolutions for every one of the winch. If a heavy fly be put upon the axle B, near the winch, it will aſſiſt greatly in regulating the motion.

If the cog-wheel that turns the trundle or trundles of a mill be placed horizontally, horizontal levers may be fixed into its vertical axis, and horſes applied to theſe for turning the mill; which is often done where water cannot be had for that purpoſe.

The uſe of mills and mill-ſtones, according to Pauſanias, was firſt invented by Myla, ſon of Meleges, firſt king of Sparta; though Pliny attributes the invention of every thing belonging to bread and baking, to Ceres: Polydore Virgil was not able to diſcover the author of ſo uſeful a machine. It is doubted whether or not water-mills were known to the Romans, there being no mention made, in the Digeſt, but of mills turned by ſlaves and aſſes. Salmaſius, however, and Gothofred, will not allow water-mills to have been unknown to the ancient Romans, though they were not in ordinary uſe. Wind-mills are of much more modern invention; the firſt model of theſe was brought from Aſia into Europe in the time of the holy wars.

Mill is alſo uſed for any machine, which being moved by ſome external force, ſerves to give a violent impreſſion on things applied to it.

Mills, in this ſenſe, are machines of vaſt uſe in the manufactures, arts, and trades; for the making and preparing divers kinds of merchandizes. The principal are thoſe which follow.

Mill, *Colour*. Colours for the uſe of painters, paper-ſtainers, &c. are prepared, in the large way, by grinding them, either with oil or water, in mills worked formerly by horſes, but now frequently ſteam-engines are uſed for ſuch purpoſe in London. Theſe colour-mills conſiſt of a large toothed-wheel, or cog-wheel, worked by the horſes, or ſteam-engine, &c. which gives motion to ſeveral trundles and upright ſpindles of ſmall mill-ſtones placed round its circumference. The conſtruction and uſe of theſe will be readily comprehended from the following deſcription of a ſingle pair of ſtones to be worked by hand, *Plate* XXXV. *fig.* 1. The winch-handle A gives motion, by the labour of a man, to the ſpindle B and fly-wheel C, fixed thereon; and which alſo carries a ſmall ſpur-wheel D, having eighteen bevelled teeth, which work into thoſe of the crown-wheel E E, of twenty-ſix teeth, fixed upon the upright ſpindle F, working in a braſs collar at top, fixed to the piece of wood G, which is adjuſtable by means of the wedge H, ſo as to keep the teeth of the wheels properly in geer: the bottom of the ſpindle works in the end of a braſs ſcrew R, working in the bottom framing of the machine, and paſſing up through the centre of the lower ſtone, the turning of which ſcrew, occaſionally, adjuſts the diſtance of the ſtones, which are of the common conſtruction, exactly like thoſe for grinding flour, but ſmaller, each being ſixteen inches diameter and three inches thick. The upper ſtone I is ſupported on the upright ſpindle F by a ſhoulder and crow, the ſame as mill-ſtones in general; it has a hopper K affixed to it, and which revolves with it, into which the ſemi-fluid colours intended to be ground are put, and when ground they are protruded through a ſpout from the tub M, nineteen inches diameter, which contains the ſtones.

After the above proceſs, colours for the uſe of painters, &c. were ground by hand with oil or water, on a poliſhed marble ſlab with a pebble muller; but this proceſs being tedious and expenſive, as well as highly prejudicial to the health of the workman, Mr. James Rawlinſon of Derby, ſome years ago contrived a mill for this purpoſe, which is repreſented in *fig.* 2, a model of which he preſented to the Society of Arts in the Adelphi, London, in 1804. A is a roller or cylinder of black marble, truly formed and well poliſhed, $16\frac{1}{2}$ inches diameter and $4\frac{1}{2}$ inches broad; B is a concave muller, covering one-third of the roller, of the ſame kind of marble, well poliſhed, and fixed in the wooden caſe or frame *b*, which is hung on hinges at *i*, for uſe when the muller requires to be lifted off the cylinder. C is a crooked bar of iron, about an inch broad, moveable on a pin at *f*, in order to turn down out of the way when the muller is to be lifted off: near the end of this bar is a thumb-ſcrew *c*, whoſe end acts in a hole in the wooden caſe *b*, and ſerves to keep that and the muller ſteady, and to increaſe the preſſure of the muller as occaſion may require. D is a ſcraper or taker-off, made of a piece of clock-ſpring fixed in an iron frame K, in the manner of a frame-ſaw, and turning on centres *d d*, ſo that when in uſe the taker-off lies in an inclined poſition againſt the cylinder, and at other times is turned back out of the way. H is a plate ſet under the taker-off to catch the colour when ſufficiently ground, which ſtands upon a ſliding board that can occaſionally be drawn out, to remove any colour which may accidentally drop from the cylinder. F is a drawer under the mill for holding curriers' ſhavings, for cleaning the cylinder and muller, when a freſh colour is wanted to be ground. The colour, roughly ground in a large colour-mill above deſcribed, is applied in proper quantities, by means of a knife, to the front of the cylinder above the taker-off, and by means of the winch-handle G the mill is worked, until the colour, by paſſing between the revolving stone and muller, is sufficiently ground; when the taker-off D, which during the operation lay back, is turned against the stone, the winch-handle is turned the reverse way for a few revolutions, in order to scrape off the colour which falls into the dish H.

In the Philosophical Transactions, No. 87, a mill is described as having been used by Dr. Langelot, for grinding leaf gold to powder, for the fanciful purpose of preparing *Aurum potabile*: the principles of this mill were, some years ago, found applicable to the grinding of dry indigo in Mr. Taylor's manufactory at Manchester, and were also found by Mr. Rawlinson, above mentioned, to be the best adapted for finely pulverizing the dry colours intended to be ground with oil or water in his colour-mill. This simple mill is represented in *fig.* 3, where L is a marble mortar, nicely formed and polished; M is a muller nearly in the form of a pear, having an iron axis fixed into its upper end, which is bent into the form of a crank at P to serve as a handle for turning the muller: the axis is fixed, when in use, into two collars O, O, in beams of wood N N, so as to revolve easily and truly in the axis of the mortar. This muller is shewn separately at *fig.* 4, which shews a slit that is made through it, almost dividing it into two parts; this slit is of use in collecting the colour which is grinding, and bringing it continually under the muller. A circular board in two halves, with a centre-hole to fit the axis, is used to lay over the mortar, to prevent the dust of the colours from flying out, to waste the same and injure the health of the workmen. By means of the flat perforated weights R, on the top of the axis, any required pressure can be applied upon the muller.

For preserving the health of such colour-men and painters as still prefer the common stone and muller for grinding their colours, M. Boulard, in the Journal de Physique, recommends an apparatus represented in *fig.* 5, wherein the stone, and its table A B, is surrounded by a close-sided casing of boards C, C, fitted to the floor of the room, and leaving a space of about $\frac{1}{16}$th of an inch wide all round the table supporting the stone; this is for emitting a current of fresh air, which is to be supplied by a pipe D D extending from a hole in the floor under the case, to the outward air in some most convenient place. Over the stone a glazed pyramid E E and metal tube F is supported by the irons G and braces H, H, H, or by other more convenient means, so that the pyramid E E projects, on all sides, about three inches beyond the stone; and at a height above the same no greater than is sufficient for the free admission of the workman's arms to work the muller, and with his pallet knife to scrape together the colour when requisite, and which he will be able perfectly to see to do, through the glass in the frame, without inhaling the vapour from the colours, but which are to be made to ascend through the tube F, and pass off into the open air through the tube M M, by means of a small stove I I closely jointed to the tubes F and G, which is to be kept burning during the hours of work, in order to produce a current between the pipes D and M, that may effectually carry off the contaminated air which has been in contact with the colours on the stone, along with their effluvia. K represents the door of the fire-place, and L that of the ash-hole of the stove, both contrived to shut very close. In the pipe F a register N should be made for regulating the burning of the stove, by the admission of more or less air thereto through the pipe F. If desirable, the close pipe F may be conducted into the fire-place of any stove or fire in the apartments above, or it may even descend by a proper curvature, so as to admit of the stove I I being placed on the ground, and applied to any useful purpose, as the boiling of oil, or heating an adjoining room, &c.

Mill, *Cotton*. See Manufacture *of Cotton*.

Mill, *Flood*, that sort of mill which is contrived for the purpose of raising water in order to discharge it from fens, marshes, and other similar kinds of land.

Mills, *Forge*, turned by water, serve to raise and let fall one or more huge hammers, to beat and form the iron into bars, anchors, and other massive works. They are also called tilt-mills. See Forge, Iron, and Steel.

Mill, *Fulling*, is a water-mill which raises and beats down large wooden pistons in proper vessels called *pools*, or *troughs*; in order to full, scour, and cleanse woollen stuffs. See Fulling-*Mill*.

Mill, *Gunpowder*, is that used to pound and beat together the ingredients whereof gunpowder is composed.

This is done in a kind of iron or brass mortar, by means of iron pestles wrought by a wheel, without-side the mill, turned by the water falling on it. See Gunpowder.

Mills, *Leather*, are used to scour and prepare with oil, the skins of stags, buffaloes, elks, bullocks, &c. to make what they call *buff-leather*, for the use of the soldiery.

This is effected by means of several large pistons, rising and falling on the skins, in large wooden troughs, by means of a wheel without-side, turned by the force of water.

Mills, *Linen*, do not differ much from fulling-mills. Their use is, to scour linens, after their having been first cleansed when taken out of the lixivium, or ley. Some of these go by water, and the generality by horses.

Mills, *Oil*, when turned by men, water, hand, or horse, serve to bruise or break the nuts, olives, and other fruits and grains, whose juice is to be drawn, by expression, to make oil. See Oil.

Mill, *Paper*, a water-mill, furnished with engines containing cylinders furnished with teeth which cut and grind the rags or cloth in a kind of wooden trough; and thus, by reducing them to little pieces, turn them into a kind of pulp, by means of water conveyed into the troughs by a pipe for that purpose. See Paper.

Mill, *Sawing*, is a water-mill, serving to saw several planks or boards at the same time.

These are frequent in France, especially in Dauphiné.

They were lately prohibited in England, where they were begun to be introduced, from a view to the ruin of the sawyers, which must have ensued. See Sawing, also Machinery, *Block*.

There are also *silk* mills, for spinning, throwing, and twisting silks; which are large round machines in form of turrets, five or six feet high, and six yards in diameter; which, being turned, either by the force of water or that of men, work at the same time an infinity of bobbins fastened thereto, whereon the silk had been wound to be here spun and twisted.

There are abundance of mills of this kind in France, especially about Lyons and Tours, some of which are so disposed, as that three of them will go at the same time, and by the same wheel wrought by water or by strength of hand. That in the Hôpital de la Charité at Lyons, is wonderful, a single man working no less than 48 of these mills. See Silk, and Winding *of Silk*.

Mill, *Stamping*. See Stamping.

Mill, *Sugar*, is a machine that serves to bruise the sugar-canes, and express the liquor or juice contained therein. The sugar-mills are very curious contrivances. Of these there are four kinds, being turned either by water, wind, men, or horses.

Those turned by the hand were first in use; but they are now laid aside, as being an intolerable hardship on the poor

negro

negroes who were doomed thereto, besides the slowness of their progress.

Wind-mills are the most modern: but they are yet somewhat rare, excepting in St. Christopher's and Barbadoes, and among the Portuguese. These make good dispatch, but have this inconvenience, that they are not easily stopped; which proves frequently fatal to the negroes who feed them. See SUGAR.

MILLS, *Tan* or *Bark*, wrought by water or horses, serve to cut certain barks into a coarser sort of powder, proper for the tanning of hides, &c.

MILLS *for Sword-blades* are likewise moved by water. They are frequent at Vienne, in Dauphiné. By working heavy hammers they forge those excellent sword-blades, called *blades of Vienne*.

The uses and operations of these several mills, more at large, see under PAPER, FULLING, SUGARS, &c.

MILL, *Threshing*, such a machine as is contrived for the purpose of threshing grain or other sorts of seed crops. See THRESHING *Machine*.

MILL, in *Coinage*, is a machine used to prepare the laminæ, or plates of metal, and to give them proper thickness, hardness, and consistence, before they be struck, or stamped.

This machine has not been long known among us; but is of some standing in Germany. It consists of several wheels dented like those of clocks, &c. which move two cylinders of steel, between which the metal is passed to be brought to its proper thickness. It was first turned with water, since with horses. See COINAGE.

MILL, in *Commerce*, a money of account in the United States of America; 1000 mills being = 100 cents = 10 deniers = a dollar.

MILL, among *Gold Wire Drawers*, is a little machine consisting of two cylinders of steel, serving to flatten the gold or silver wire, and reduce it into laminæ, or plates. See GOLD *Wire*.

They have also mills to wind the gold wire or thread on the silk: these are composed of several rows of bobbins all turned at the same time.

MILL-*Reek*, in *Medicine*, an appellation given by the miners, employed at the Leadhills in Scotland, to those affections of the bowels, and of the nervous system, which are occasioned by the poison of the lead. The melting-houses, in which the operations are carried on, are called *mills*, because the bellows there are worked by water-wheels; and the *reek*, or smoke, arising from the melted lead, is believed to be the chief cause of the disease: whence the term *mill-reek* has been appropriated to the malady. See Essays and Obs. Phys. and Liter. vol. i. art. xxii. Edinburgh.

MILL-*Dams*, in *Rural Economy*, the basons which contain the water for supplying mills. A very firm way of making these in a quick or running sand, which is usually found a very troublesome circumstance in the making of them, is by laying the foundation with unslaked lime; which, by slaking among the sand, runs together into a hard stone, which gives a very firm and sure foundation. Plott's Staffordshire, p. 336.

MILL-*Holms*, a term applied to the low meadows, and other fields in the vicinity of mills, or watery places about mill-dams. The soils in these cases are generally of a good quality.

MILL-*Pool*, a stock or pond of water, by the force of which the motion of a water-mill is effected.

The dam of a mill-pool is raised much in the same manner as directed for *fish-ponds*; which see.

MILL-*Stones*, in *Rural Economy*, the prepared stones made use of in grinding grain and other substances, which are of different kinds, according to the purposes for which they are employed, but those chiefly used in grinding wheat into flour, were formerly imported from France, and termed *burrs*. Lately, however, stones proper for this use have been discovered in different parts of this kingdom, as in Wales and Scotland. In the first of these places they were found by Mr. Bowes, in a quarry which is "situated within the corporation liberties of Conway: the stone appears within a quarter of a mile of that town, and extends from east to west for the distance of two miles, appearing in most places upon the surface within that distance. Such an immense body of the stone has been left bare and exposed to view, that the industry of ages would scarcely lessen it. A deep chasm intervenes at the end of two miles; and, on examining the same line across this valley, he found the stone mixed up with various other fossil substances, to which it seems to bear no relation. In the next rise of mountains it resumes its quality, and takes a southerly direction, passing through a range of hills to the distance of two miles more, where the vein disappears. It is every where the highest stratum; and when disengaged from the quarry where now worked, it tumbles down the side of the mountain to the plain within five hundred yards of the shipping-place, where small vessels may lie safely in all weathers at a natural quay, completely calculated for this business." The quarry lies on the decline of a hill: the vein now is about eight yards wide; but he has reason to suppose it wider below. At the depth he has sunk, which is at least twenty-five feet, the stone mends in quality. When first taken from the quarry it is much softer and easier wrought into shape, than when exposed to the air: even a day makes a difference. The vein appears to him quite inexhaustible, and contains every variety of the stone, cellular, close, hard, or soft. The right in this tract of country has been presented to him, by Mr. Sneyd of Staffordshire, under the hope that he might be able to make this discovery, and carry it vigorously into effect, in which he has not been disappointed.

It would appear from the evidence sent to the Society for the Encouragement of Arts, &c. that the stones raised from this quarry are capable of being employed in most cases where those imported from France have been in use, and that the stone, from its external appearance, seems to be constituted of quartz and cherts.

And in the latter of the above situations stones fit for this use were discovered by James Brownhill, miller, "who, when the late unfortunate war had rendered the getting of the French burr extremely difficult, as he was passing by the great basaltic rock of the Abbey Craig, near Stirling, examined the texture of several masses of the stones; and found one species, which appeared to him fit for the grinding of wheat, and brought home a sample of them, which he shewed to Mr. Alexander Ball, agent of the Alloa Mills, who agreed to make trial of a pair. They were built under his direction in the same manner as the French burr; and, on their being put to work, gave such satisfaction to the customers of the mills, as induced the Alloa Mill company to have another pair built, and totally lay aside the French burr mill-stones." It is suggested, that "the French burr stones are so porous, as to make it necessary to fill up the cavities with a preparation of alum: this considerable expence is saved by the uniform texture of the basaltes; and their superior excellence is so apparent, that upwards of 60 pair are now at work in several parts of the kingdom, and the demand for them is daily increasing." In addition it is stated, that "the basaltes mill-stones are not only excellent for manufacturing of flour, but for all kind of grist. The distillers give them a decided preference, and they grind oats in in a very complete ſtyle, as the meal is returned quite free of ſand, which is a great deſideratum for thoſe places where oat bread is in uſe. The diſcoverer of this uſe of the baſaltes, builds mill-ſtones of all ſizes on moderate terms, and is careful, from his experience as a miller, to build them of ſuch a grain as is moſt ſuitable for the particular purpoſes for which they are intended.

The following remarks are offered by Mr. Ferguſon on the ſize and velocity of mill-ſtones. The diameter of the upper ſtone is generally about ſix feet, the lower ſtone about an inch more; and the upper ſtone, when new, contains about 22½ cubic feet, which weighs ſomewhat more than 19,000 pounds. A ſtone of this diameter ought never to go more than 60 times round in a minute; for if it turns faſter, it will heat the meal. But according to Mr. Imiſon, the mill-ſtone ſhould turn twice round in a ſecond of time, and ſhould only be four feet and a half in diameter. It may probably be imagined, that the meal will be much heated by ſuch a rapid motion as he has recommended, but the effect is counteracted by diminiſhing the ſize of the mill-ſtone from ſix feet to four and a half. The velocity of the circumference of the ſmall mill-ſtone moving twice round in a ſecond, is only one-third greater than the velocity of the large mill-ſtone moving once round in a ſecond.

It may be noticed, that in the former of the above quarries mill-ſtones are raiſed which are of much larger ſizes than the French burrs, which may probably be an advantage in ſome caſes.

The modes of preparing mill-ſtones for the purpoſe of grinding have been deſcribed already, and *fig.* 6. of *Plate* XXXV. repreſents the ſurface of the under grinding mill-ſtone, the way of laying out the wads or channels: the wooden buſh is fixed into the hole in the middle, in which the upper end of the iron ſpindle turns round; and the caſe or hoops that ſurround the upper one, which ought to be two inches clear of the ſtone all round its circumference. B ſhews the upper grinding mill-ſtone, and iron croſs or rynd in its middle, in the centre of which is a ſquare hole that takes in a ſquare on the top of the iron ſpindle, to carry the mill-ſtone round: when the working ſides or faces of the mill-ſtones are laid uppermoſt, the wads muſt lie in the ſame direction in both, that when the upper ſtone is turned over, and its ſurface laid on the under one, then the channels croſs each other, which aſſiſts in grinding and throwing out the flour; the wads are alſo laid out according to the way that the upper ſtone revolves. In theſe the running mill-ſtone is ſuppoſed to turn *ſunways*, or what is called a right-handed mill; but if the ſtone revolves the other way, the channels muſt be cut the reverſe of this, and then it is termed a left-handed mill. See Mill.

The mill-ſtones which we find preſerved from ancient times, are all ſmall, and very different from thoſe in uſe at preſent. Thoreſby mentions two or three ſuch found in England, among other Roman antiquities, which were but twenty inches broad; and there is great reaſon to believe that the Romans, as well as the Egyptians of old, and the ancient Jews, did not employ horſes, or wind, or water, as we do, to turn their mills, but made their ſlaves and captives of war do this laborious work; they were in this ſervice placed behind theſe mill-ſtones, and puſhed them on with all their force.—Sampſon, when a priſoner to the Philiſtines, was treated no better, but was condemned to the mill-ſtone, in his priſon. The runner, or looſe mill-ſtone, in this ſort of grinding, was uſually very heavy for its ſize, being as thick as broad. This is the mill-ſtone which it is expreſsly prohibited in Scripture to take in pledge, as lying looſe it was more eaſily removed. The Talmudiſts have a ſtory, that the Chaldæans made the young men of the captivity carry mill-ſtones with them to Babylon, where there ſeems to have been a ſcarcity at that time; and hence, probably, their paraphraſe renders the text "have borne the mills, or mill-ſtones;" which might thus be true in a literal ſenſe. They have alſo a proverbial expreſſion of a man with a mill-ſtone about his neck; which they uſe to expreſs a man under the ſevereſt weight of affliction. This alſo plainly refers to this ſmall ſort of ſtones.

Mill-*Work*. Under this head we intend to treat of the parts and mechanical contrivances uſed in mills. Under the article Machinery, the reader will find obſervations of a ſimilar nature to thoſe of the preſent article, but applied to ſmaller and more delicate machines than thoſe which are uſually denominated mills.

The object of this article will therefore be, to give a general account of the moſt important pieces of mill-work, as cog-wheels, ſhafts, bearings, &c.; which parts being common to mills of all kinds, would, if minutely deſcribed under every head where they are employed, introduce a great many needleſs repetitions.

The different firſt movers of mills will be treated of, and deſcribed under their ſeveral heads of Steam-*Engine*, Water-*Wheels*, and Wind-*Mill;* and the acting machines of ſeveral kinds of mills, as clay-mill, grinding-mill, under Cutlery; fulling-mill, flour-mill, iron-mill, under Manufacture *of Iron*; oil-mill, cotton-mill, under Manufacture *of Cotton;* rolling-mill, ſpinning-mill, ſilk-mill, thraſhing-mill, water-mill, ſawing-mill, under Machinery *for manufacturing Ships' Blocks at Portſmouth*; Tilt *Mill*, &c. &c.

Cog-wheels are the moſt important and numerous parts of mill-work, few mills being without them, to modify the direction, and adapt the power of the firſt mover, which actuates the mill, to the working point, or the machine which performs the operations the mill is intended for. Moſt mills contain ſeveral different kinds of machines, or operative parts, all deriving their motions from the ſame ſource, or firſt mover. Thus, a flour-mill contains ſtones for grinding; dreſſing machines for ſifting the flour; ſack tackle, for drawing up the ſacks, &c.; all which are moved by the ſame firſt mover as a water-wheel, wind-mill, ſteam-engine, or horſe-wheel. But each of theſe machines requires to be moved with a different velocity to perform its work in the beſt manner; and it is the object of the mill-work to obtain theſe different velocities from the ſame firſt mover, chiefly by the means of wheels; which, therefore, from their importance, deſerve the firſt notice. There are a variety of cog-wheels, as ſpur-wheels, (or *gear* in the technical phraſe,) bevil-wheels, face-wheels or crown-wheels, pinions or nuts, trundles or lanterns; with a variety of other names which are local, but have the ſame ſignification with ſome of the above.

Spur-wheels are thoſe in which the teeth project from the periphery of the wheel, in the direction of radials (ſee *Plate* I. *fig.* 1. *of Mill-work*): they are ſo called, from the reſemblance to the rowel of a ſpur. A ſpur-wheel is uſed to communicate motion by its teeth to another, ſituated in the ſame plane; conſequently, the axes of the two are parallel to each other. The ſpur-wheel, at other times, works with *a pinion*, or nut (ſee *fig.* 2.), which is in fact a ſpur-wheel of ſmall ſize: at other times with a *trundle* or *lantern*. This is a pinion of peculiar conſtruction, conſiſting of two circular boards A, A, (*fig.* 3.) fixed, at ſome diſtance apart, upon its axis of motion or ſhaft B B, and united by a number of cylindrical pins *a*, *a*, called ſtaves, or rounds, which are arranged in a circle, and fixed parallel to the axis of the trundle between the two boards of it. The teeth of the wheel act

act upon these rounds to give motion to the trundle; the rounds, therefore, must be the same pitch or distance asunder as the cogs of the wheel. The number of the rounds of the trundle of course determine its diameter. Trundles have of late years fallen into disuse among mill-wrights, cast iron pinions being found much more preferable: they were sometimes used to work with spur-wheels, but more commonly with

Face-wheels, see *fig.* 4. In these, the teeth or cogs are fixed perpendicularly to the plane of the wheel, parallel, therefore, to its axis: they were used to work with another similar wheel, or with a trundle with a spur-wheel, or with a pinion, when the two axes were required to be perpendicular to each other, as shewn in *figs.* 3 and 4.

The crown or face-wheel has of late years been almost wholly superseded by bevil-wheels, which, in all situations where a wheel is required to turn another in a direction perpendicular or inclined to itself, are found vastly superior.

Bevilled or *Mitre-wheels*, see *fig.* 5. of the plate, have their teeth formed upon a conical surface, the angle of the cone being the same as the angle the axes C, D, of the two wheels A, B, make with each other. The introduction of this class of wheels into machinery is a very essential improvement, which has been wholly made within these thirty years. Bevil-wheels are of course always used to work with others of the same kind.

The manner of setting out the teeth of cog-wheels, in such a form that they shall act in the most equable manner upon each other, and with the least friction, has been a subject of much investigation among mathematicians and theoretic mechanics; but the practice and observation of the mill-wrights have produced a method of forming cog-wheels, which answers nearly, if not fully as well in practice, as the geometrical curves which theory has pointed out to be the most proper. This they have effected by making the teeth of the modern wheels extremely small and numerous. In this case, the time of action in each pair of teeth is so small, that the form of them becomes comparatively of slight importance; and the practical method of the mill-wrights (using arcs of circles for the curves) approximates so nearly to the truth, that the difference is of no consequence: and this method is the best, because it so easily gives the means of forming all the cogs exactly alike, and precisely the same distance asunder, which, by the application of any other curve than the circle, is not so easy. The method, which is extremely simple, is explained by *fig.* 1. The wheel being made, and the cogs fixed in much larger than they are intended to be, a circle, *a a*, is described round the face of the rough cogs upon its *pitch diameter*, that is, the geometrical diameter, or acting line of the cogs; so that when the two wheels are at work together, the pitch circles, *a*, *a*, of the two are in contact. Another circle, *b b*, is described within the pitch circle for the bottom of the teeth, and a third, *d d*, without it, for the extremities. After these preparations, the pitch circle is accurately divided into the number which the wheel is intended to have: a pair of compasses are then opened out to the extent of one and a quarter of these divisions, and with this radius arcs are struck on each side of every division, from the pitch line *a* to the outward circle *d d*. Thus, the point of the compasses being set in the division *e*, the curve *f g* on one side of the cog, and *n o* on one side of the other, are described; then the point of the compasses being set on the adjacent division *k*, the curve *l m* is described. This completes the curved portion of the cogs *e*, and this being done all round completes every tooth: the remaining portion of the cog within the pitch circle, *a*, is bounded by two straight lines drawn from the points *g* and *m* towards the centre; this being done to the cogs all round, the wheel is set out, and the cogs, being dressed or cut down to the lines, will be formed ready for work, every cog being of the same breadth; and the space between every one and its neighbour is exactly equal to the breadth, provided the compasses are opened to the extent of one division and a quarter, as first described.

Many different methods of forming teeth have been proposed, among them the following: Let the tooth *a* (*fig.* 6.) press on the tooth *b* in the point C; and draw the line F C D E perpendicular to the touching surfaces in the point C: draw A F, B E, perpendicular to F E, and let F E cut the line A B in D. It is plain from the common principles of mechanics, that if the line F E, drawn in the manner now described, always pass through the same point D, whatever may be the situation of the acting teeth, the mutual action of the wheels will always be the same. It will be the same as if the arm A D acted on the arm B D. In the treatises on the constructions of mills, and other works of this kind, are many instructions for the formation of the teeth of wheels; and almost every noted mill-wright has his own nostrums. Most of them are egregiously faulty in respect to mechanical principle. Indeed, they are little else than instructions how to make teeth clear each other without sticking. Dr. Hooke was, we think, the first who investigated the form of teeth which procured this constant action between the wheels; and in a very ingenious dissertation, published among the Memoirs of the Academy of Sciences at Paris, 1668, this gentleman shews that this will be ensured by forming the teeth into epicycloids. Mr. Camus, of the same academy, has published an elaborate dissertation on the same subject, in which he prosecutes the principles of M. De la Hire, and applies it to all the varieties of cases which can occur in practice. There is no doubt as to the goodness of the principle, and it has another excellent property, "that the mutual action of the teeth is absolutely without any friction." The one tooth only applies itself to the other, and rolls on it, but does not slide or rub in the slightest degree. This makes them last long, or rather does not allow them to wear in the least. But the construction is subject to a limitation which must not be neglected. The teeth must be so made, that the curved part of the tooth *b*, is acted on by a flat part of the tooth *a*, till it comes to the line A B in the course of its action; after which the curved part of *a* acts on a flat part of *b*, or the whole action of *a* on *b* is either completed, or only begins at the line A B, joining the centres of the wheels.

Another form of the teeth secures the perfect uniformity of action without this limitation, which requires very nice execution. Let the teeth of each wheel be formed by evolving its circumference; that is, let the acting face G C H of the tooth *a* have the form of a curve traced by the extremity of the thread F C, unlapped from the circumference. In like manner, let the acting face of the tooth *b* be formed by unlapping a thread from its circumference. It is evident that the line F C E, which is drawn perpendicularly to the touching surfaces in the point C, is just the direction or position of the evolving threads by which the two acting faces are formed. This line must, therefore, be the common tangent to the two circles or circumferences of the wheels, and will, therefore, always cut the line A B in the same point D. This form allows the teeth to act on each other through the whole extent of the line F C E, and, therefore, will admit of several teeth to be acting at the same time; (twice the number that can be admitted in Mr. De la Hire's method.) This, by dividing the pressure among several teeth, diminishes its quantity on any one of them, and, therefore diminishes the dents or impressions which they unavoidably

 make

make on each other. It is not altogether free from fliding or friction, but the whole of it can hardly be faid to be fenfible. The whole fide of a tooth three inches long, belonging to a wheel of ten feet diameter, acting on the tooth of a wheel of two feet diameter, does not amount to $\frac{1}{10}$th of an inch, a quantity altogether infignificant. Conical wheels, or bevilled gear, may be confidered as confifting of two cones rolling on the furfaces of each other: let B and C, (*fig.* 7.) be the bafes of two cones turning on their centres, having teeth cut on them diverging from the apex A to the bafes B and C. Thefe teeth will work freely into one another from the apex A to the bafes B and C, when turned round; but the teeth near the point of the cone being fmall and of little ufe, may be cut off at G and H. Thefe teeth may be made of any breadth, according to the ftrefs they are intended to bear; and this is of vaft importance, becaufe by this method they may be made to overcome a much greater refiftance, and work fmoother than a face-wheel and trundle of the common form. Befides, thefe kind of wheels are of fingular ufe to communicate motion in any direction, or to any part of a building, with lefs trouble and friction than wheels of any other conftruction.

We fhall now venture fome remarks upon the manner of conftructing wheel-work. Cog-wheels were formerly made of wood, and fome are ftill conftructed of that material; but of late years caft-iron wheels have been fubftituted, and found much fuperior in ftrength, accuracy, and durability. Wooden wheels are framed together in fegments ufually of three thickneffes, to break the joints upon each other. (See *fig.* 1.) The middle thicknefs is made in fix or eight pieces, and left on the infide with ftraight fides, *x*, *x*, into which the arms are fitted, and bolted againft it. On each fide this middle thicknefs, another is (X X, *fig.* 1.) placed with break joints, and all the three are bolted together to make a folid rim, in which the cogs are to be fixed by mortifes, the tenons or tails of the cog being held in their places by a pin driven through each. The arms of wooden wheels are made in different ways; fometimes they are mortifed through the fhaft, and the ends are notched in the middle of the fides of the octagonal pieces *x*, *x*, and laying againft the face of them behind, are bolted to them to make all faft. This manner of uniting the arms with the rim is fhewn at *l* (*fig.* 4.); but this method is not the beft, becaufe the mortifes weaken the fhaft very materially, and it is difficult to get fuch a wheel off if ever it is required, on a failure of the fhaft, &c. On this account, the method called clafp arms is much preferable: it is fhewn in *fig.* 1. Four arms E E, F F, are ufed, which are halved into each other, and form a frame as in the figure, leaving a fquare opening in the centre, and holding the rim of the wheel by their ends, which are bolted to the middle thicknefs of the rim, as fhewn in *fig.* 4. To fit on fuch a wheel as this, the fhaft is made up to a fquare, by fixing pieces of wood upon its fides; and the wheel being hung upon this, is made faft by wooden wedges driven in all round, the fquare formed between the arms being rather larger than the fhaft, by which means the wheel can be adjufted to come quite true by the wedging. Face-wheels, like *fig.* 4, have fometimes ftays or braces proceeding from the back of the rim to fome diftance along the fhaft, where they are received in mortifes, as fhewn by the dotted lines: thefe make the wheel exceedingly ftrong, and keep it very ftiff in the fquare upon its axis, which is very neceffary, as the action of the teeth of a face-wheel meeting a trundle, is to throw the wheel back upon its fhaft, which tendency thefe ftays effectually counteract. At other times, two fets of clafp arms are ufed for the fame end, one bolted on each fide of the middle thicknefs of the wheel, by the fame bolts which pafs through both, as well as the wheel, and unite the two fets like one, but of confiderable depth, fo that the wedging will have a greater effect to keep the wheel in the fquare. Small wheels are frequently made of plank, folid, without any arms. In this cafe the middle thicknefs is made of four pieces, leaving a fquare hole between them, and they are kept together by a circular ring of fegments, bolted on at each fide all round, and the joints overlapped. The conftruction of trundles (*fig.* 4.) has been fufficiently explained, except that they ufually have an iron hoop fitted round the circular boards to prevent them from fplitting: indeed many large face-wheels have the fame. Small pinions are made out of one block of wood, and the cogs are fitted into it much in the fame manner as the fpokes are let into the nave of a coach-wheel. Iron-wheels either have the cogs caft in the fame folid piece with the rim, or mortifes are left in the caftings for the reception of wooden cogs, as thefe are found to work much better. The wheel and its arms are fometimes caft in one piece, but for large wheels the rim and its arms are formed in two feparate pieces and fcrewed together. The reafon of this is, that in cafting a large and extended piece of iron, it frequently happens that fome parts will cool in the mould, and become folid before the others: confequently, from their contraction, thefe parts will be fhorter than others which have retained their heat and fluidity longer. This circumftance happening to the arms of a wheel, will either warp the rim out of a true circle, or fet the metal of one part upon a ftrain againft another, fo that the flighteft blow or jar will caufe them to fnap in fuch parts. All this danger is avoided by making them in feparate pieces, as in *fig.* 8: the end of each arm, as A B, has a flat expanded part, which lays againft a proper focket withinfide of the rim C D, and is bolted to it. One-half of this wheel is delineated, with wooden cogs fitted in, at C D; and the other half, F F, fhews the form of a rim, where the cogs and the arms *e f* are caft all in one piece. In the latter cafe the rim has a rib *g* withinfide it for ftrength, in the fame manner as all the arms have, and which is evidently fhewn by the figure. In fome fituations it is neceffary to fix wheels upon long fhafts while they are in their places, and cannot conveniently be taken down: in this cafe fuch wheels may be made in two halves bolted together. *Fig.* 9. is drawn as if it were two halves of different kinds put together in this manner; the joint being up the middle of the arms L, L, and the connecting bolts are plainly fhewn. By this method one wooden pattern, if very accurately made, will ferve for cafting both halves of the wheel. Cog-wheels are found to work with leaft friction, wear, or noife. When one has wooden, and the other iron cogs, dreffed exceedingly fmooth and true, the fmall wheel is ufually made with the iron teeth, and the large one with the wooden ones. When fuch wheels are firft fet to work, the cogs are fmeared with black lead mixed with tallow: this gives them a gloffy furface, which greatly diminifhes the friction. Hornbeam is found to be the beft wood for the cogs, as it is not liable to fplit or fplinter away by long wear. The cogs are held in by a pin driven through the tenon or tail, withinfide the rim of the wheel. The wooden cogs are dreffed by chiffels to the marks fet out, in the fame manner as wooden wheels; but the iron cogs are firft chipped with a cold chiffel and hammer, and then filed true. The great labour of doing this induced Meffrs. Boulton and Watts, fome years ago, to erect machinery for dreffing cogs. The wheel was provided with apparatus to hold it faft at the feveral divifions, and a ftrong flider, with a chiffel fixed in it, was forced between the rough cogs by the revolution of a camm or heart, with

with a ſufficient power to cut away a ſhaving, and form the cog perfectly at twice repeating the operation. Some mechanics diſpute the propriety of dreſſing iron cogs at all; they ſay, that the exterior ſurface of the caſtings have a kind of caſe-hardening, which is removed by the dreſſing, and a ſofter ſubſtance of metal expoſed for the acting ſurfaces. This is true, and the objection would have its full force, if it were poſſible to make caſtings of wheels perfectly true in the circle, and all the cogs preciſely the ſame ſize: but as the preſent ſtate of the founder's art cannot inſure this, it is beſt to chip and file the cogs; accuracy in the form of the teeth being a ſuperior conſideration to any quality of their ſubſtance. The wheel being made in either of theſe methods, muſt next be fixed, or *hung*, upon its ſhaft. Wheels are generally fixed faſt upon their ſhafts or axles before their teeth are ſet out; or, if this is not convenient, they are fixed on a temporary ſpindle to ſet them out. When the wheel is made of wood, it is fixed upon the ſhaft, or a temporary axis, and turned round upon its pivots, while a chiſſel is laid on ſome fixed ſupport to cut or turn its circumference to a true circle, or elſe to make a mark to which its rim may be reduced all round. The circumference is then divided, and mortiſes cut out for every cog; and when theſe are fixed in they are much larger than they are intended to be, that they may be ſet out, as above directed, and reduced to their true figure, without abſolutely depending upon the accuracy of the mortiſes which receive them. Iron wheels are, as before-mentioned, treated in a different manner, being caſt in the impreſſion of a truly circular pattern made of wood; the cogs caſt ſolid, with the rim or elſe mortiſes left all round for the reception of the wooden cogs: in either caſe the rim is a true circle, and muſt be fixed upon the ſhaft exactly by its centre, inſtead of forming the circumference to the centre, as in the wooden wheel. To do this, the centre hole through the iron wheel is made much larger than the ſhaft which is to go through it, and the ſpace all round is filled up by iron wedges driven in; ſo that by means of theſe the wheel can be fixed exactly true in the centre (or in the round), and alſo in the flat that is truly perpendicular to the axis. The manner of arranging the wedges is ſhewn in *fig.* 8, where eight wedges are ſhewn by *a, a, a, a*, &c. round the ſhaft R. It is needleſs to explain how the wheel can, by means of theſe, be ſet exactly true, when it is found by turning round upon the pivots of its ſhaft that any one ſide of the circumference is farther from the centre than another. For the purpoſe of ſetting it ſquare upon the ſhaft, each wedge-hole is provided with two wedges, one driven in from each ſide of the wheel, the two laying over each other in the notch or hole in the manner ſhewn at G. Thus, by gently driving one in, and the other a little outwards, the wheel may be very correctly rectified, if it has any deviation from the perpendicular. This is the uſual manner of hanging wheels, and for large wheels it is the only applicable method. *Plate* II. *figs.* 9 and 10, is a far ſuperior plan for ſuch iron wheels as are not too large or heavy to be turned in a lathe upon a chuck, ſo that the centre is expoſed, and may be bored through with a truly circular hole, and rather conical: of courſe the wheel is fixed upon the chuck, ſo that its circumference runs truly; and at the ſame time the centre is bored, the pitch circle is deſcribed upon the cogs, and ſometimes the ends of the cogs are turned to reduce them to a true circle, and alſo the ſides, that they may be exactly flat: for, as we have before obſerved, iron wheels, however true their teeth may be caſt, ſhould always have their cogs rather too large, and then be ſet out and dreſſed, by chiſſeling and filing, to make them perfectly correct to the lines thus deſcribed. But to return to *fig.* 9; the wheel being prepared, and its centre bored out, the ſhaft is turned, as uſual, to form its pivots, and, at the ſame time, the part which is to receive the wheel is turned conical, to fit the hole through the wheel, which being jambed thereon will certainly be true at once: and to prevent it from ſlipping round upon its axis various means are in uſe; ſometimes a mortiſe is formed through the ſhaft A, at the ſmall part of the cone, and a wedge *r* driven through, which is received in notches at the ſides of the hole through the central part of the wheel, ſo that it holds the wheel from turning round on the ſhaft, at the ſame time that it drives it hard, and fixes it upon the conical fitting. Another method is to cut a channel along the conical part of the ſhaft parallel to the axis of it, and another ſimilar one withinſide of the hole through the wheel; then a fillet or feather of iron *s*, (*fig.* 10.) being inſerted into the two grooves, effectually prevents the wheel from turning, unleſs the ſtrain is ſo great as to cut the feather in two through its whole length, which is eaſily prevented by making it of a proper thickneſs. Another method of fixing a wheel is to have a flaunch, or flat ſhoulder, formed upon the ſhaft, and the wheel is drawn up againſt this by two, three, or four ſcrew-bolts going through it, and alſo through the central part of the wheel, parallel to its axis. This plan is neither ſo neat, ſimple, nor ſtrong as the former. When a wheel is required to be ſometimes diſengaged from its axis, the conical or cylindrical fitting is very convenient. In this caſe, the wheel ſhould fit up againſt a flat ſhoulder, as *a*, in *fig.* 11, and at the oppoſite ſide ſhould have a collet, or ring *b*, to confine it, and kept up by a key going through to the ſhaft R. In this way the wheel will ſlip round freely upon its axis, and communicate no motion thereto, though it is in conſtant motion itſelf: but when they are required to be connected, a locking bayonet, or clutch-box, is uſed. Theſe pieces of mechaniſm are constructed in different forms; one of them is ſhewn in the figure. Strong arms A, A, are fixed faſt on the ſhaft R, juſt before the wheel either by a circular fitting with a fillet, by a ſquare, or they may be caſt with it. Through the extremities of theſe arms holes are drilled to receive the ſhanks *f, f*, of the locking bayonet, which are fixed by nuts faſt to an arm D, very nearly ſimilar to A A, but it ſlides on the ſhaft, and has a central part *g*, with a circular groove round it, in the manner of a pulley, and a fork embracing the central piece in this groove gives the means of ſliding the bayonets *f f*, and D, upon the ſhaft, ſo that the points of its ſhanks intercept the arms of the wheel, ſo as to carry it round with them and the ſhaft; but when the points of *f f* are drawn back clear of the arms of the wheel, it ſlips round freely upon the ſhaft. The clutch-box is rather different from this; it is a piece fitted upon the ſhaft with a fillet, ſo that it cannot ſlip round, but will ſlide endways upon it. The end of the piece is formed with ſeveral notches, or indentations acroſs its face, which meet ſimilar indentations in the face of the central part of the wheel, and thus unites the wheel and the ſhaft when the clutch is ſlid up to it; but the wheel is diſengaged when the clutch is drawn from it. The conſtruction of *bearings* for the ſupport of pivots at the ends of ſhafts or ſpindles, is a matter of great importance in mill-work. The old kind of bearing called braſſes is ſhewn in *fig.* 12. A lump of braſs *a*, with a ſemicircular notch in it, was let into the piece of timber A, which was to ſupport it; and two ſcrew-bolts *b, b*, were fixed through the timber, being half received in notches formed in the ſides or ends of the braſs *a*: the upper braſs, *b*, was exactly ſimilar to the lower, and over it a plate of iron, *d*, was placed, with two holes through it to receive the two bolts *b, b*, and keep them

them together: the nuts c, c, upon the tops of the bolts confined the upper brass down, and made all fast and tight. This kind of brass is not sufficiently strong or steady for all purposes, and, therefore, the bearing shewn in *fig.* 13. has taken its place: in this, $a a$ is a cast-iron plate, which is held by two or more bolts r, r, down upon the timber or framing of the mill: this piece of cast-iron has two pieces b, b. rising up from it, between which a piece of brass, l, is bedded, and has a semicircular notch in it. Another similar piece of brass is fixed into the cast-iron cap-piece B, which is fitted into the space between the two pieces b, b, and is drawn down by nuts upon the two bolts c, c. The brasses are prevented from getting out sideways by small fillets projecting from the middle of them, which are received into proper notches in the cast-iron work. In the same manner the cap B is fitted between the pieces b, b, with a tongue or fillet, and groove, so that it cannot deviate sideways, and then the bolts have only to draw the brasses down together. Sometimes a bearing of this kind is fitted up, so that it is adjustable in its position a little to adjust two wheels to work accurately with each other, or for other purposes where nicety is required. In this case, an iron plate, D, is bolted down to the framing, and the bearing, $a a$, lays upon it, the same bolts r, r, going through both, and also through the framing beneath; but the holes through which they pass in the piece $a a$ are oblong, to admit the whole bearing being adjusted sideways. This is done by two wedges o, o, inserted at the ends of the piece $a a$, between the two ends of D, which rise up for the purpose, as at $n n$. The bearing rests upon two wedges at g, g, and is drawn down upon them by the bolts r, r. By these two wedges it can be raised up at pleasure, and by the other two, o, o, at the ends, it can be adjusted endways to set the bearing in the exact position required; and the bolts r, r, when screwed fast, hold all tight. The best way to make the interior surface of the brasses for a bearing exactly true, is to have them cast solid, that is, the two halves of the brass in one, with a notch which very nearly, but not quite separates them. In this state it can be chucked in a chuck-lathe, and the inside bored or turned out true: then it may be sawn in two halves, and put into its place, to which it should have been previously fitted. Sometimes the bearing is all fitted together and screwed down in its place, and a borer is used to bore or broach out the hole for the brasses, the same as is employed to bore pump barrels. Brass is found, by experience, to be the best substance to form bearings for a cast-iron gudgeon, having the least friction, and, consequently, least wear, of any other substance which can be used. To diminish this friction still farther, friction-wheels are sometimes used. The manner of contructing these, when merely required to support a gudgeon, leaving its own weight to keep it down in its place upon them, is shewn in *fig.* 14. Here A A is an iron plate, which is to be bolted down upon the framing: it has holes through it to receive the friction-wheels B, B, and supports bearings a, a, for their pivots raised up to a proper height, and provided with sockets for brasses, in which the pivots of the friction-wheels are to lie. The two friction-wheels B, B, as is evident, lie by the side of each other, and the gudgeon, D, of the shaft they are to bear lies upon and between them, so that when it turns round it rolls upon them, or rather, their circumferences move with it, and, consequently, the pivots of the friction-wheels move so slowly, as to diminish the friction very materially, the proportion depending on the relation between the diameters of the wheels B and the gudgeon D. This is not the best kind of friction-wheels, though the simplest. *Plate* II. *fig.* 15. *of Mill-work*, contains a view of another kind, called friction-rollers: here A A is an iron plate bolted down to the framing, and an iron ring, B, rises up from it, all cast in one piece. The interior surface of this ring is turned in the lathe with the greatest accuracy, and the pivot or gudgeon C, which is also turned true, rests in the centre thereof, being supported by six rollers a, a, &c. arranged at equal distances round it, and of such a diameter as to exactly fill up the space all round between the gudgeon and the ring. The rollers, it is evident, must be made all of one exact diameter, and extremely true, and they must fill up the space: then the gudgeon being turned round acts upon these rollers, and turns them round also at the same time by this motion. As they have no fixed centre, they also roll round within the ring B, in the same direction as the motion of the gudgeon, but with a very slow motion, which will be in proportion to the relative diameters of the gudgeon C and the ring B. By this means nearly all the friction is avoided, nothing like the sliding of a gudgeon round upon its bearing taking place here; it is all rolling of one surface upon another: and as the contact of two cylinders, supposing them hard, is but a line, the friction, or more properly adhesion, is exceedingly small; and at the same time that the gudgeon is as strongly supported as possible: but this depends upon the hardness of the matter of the gudgeon, the rollers, and the ring B. If the ring and gudgeon are made of hard cast iron, and the rollers of steel at a spring temper, it will act extremely well, though the strain or weight upon the rollers be very great. For light strains softer substances might be used, but not to so good an effect.

The manner of keeping all the rollers at their relative distances from each other, in the ring B, that they may not run against each other, is yet to be explained. Each roller, as shewn at z, has a groove turned in it in the middle of its length, so as to reduce it to a small neck in the centre: then an iron ring, L, is provided, which has six holes drilled in it, in the proper positions for the centres of the rollers, that is at equal distances round a circle, which is as much less than the ring E as the diameter of the rollers, or the same quantity larger than the diameter of the gudgeon C. These holes are made to fit the small neck in the centre of the rollers, and to get them in, the holes are cut open from the outside of the ring, so as to become notches; then the rollers being put into them, are all in one cluster, and in this state are introduced into the ring E. They will now be kept at their proper distances asunder, and when the gudgeon C is introduced between them, they will all take their proper places, and lie truly parallel. It is to be observed that the holes or notches in the ring L, do not exactly fit the necks of the rollers, which have therefore considerable play, and but very little friction, for it is not essential to keeping the rollers at their relative distances that this ring should be used, but it will prevent the danger of their getting wrong by accident. To prevent any dust or dirt getting in, which would completely destroy the action of this ingenious mechanism, a circular iron plate is fitted into the ring B, on each side, and both are fixed by small screws going through the ring. One of the plates N must of course have a hole through the middle, to admit the gudgeon. The joints of these plates should be water tight, and then a quantity of oil being poured in, will remain in the bottom of the ring B, and every roller, as it passes, will be kept oiled; though this is no ways necessary to their action. The end plate, which is not perforated, will make a stop to prevent the gudgeon moving endways, and the two plates will keep the rollers from shifting their position on end; but to prevent friction, if ever they come in contact, the ends of the roller should be rather convex, as shewn at z, that they may touch in the centre

centre rather than the outſides; but they will never bear hard againſt the plate, having no drift that way.

A patent was taken out for theſe friction rollers many years ago, and a large manufactory was eſtabliſhed for making them for various purpoſes, as carriage and waggon-wheels, the gudgeons of heavy water-wheels, &c.: they were found to poſſeſs great advantages, having ſcarcely any ſenſible friction when in motion, but were liable to get out of order chiefly from the entrance of duſt, which occaſioned the rollers to wear out of the round more on one ſide than the others; and if once by this accident the rollers ſtood ſtill for an inſtant, the gudgeon wore a flat place in the two rollers beneath it, and they would never run round again: a very little time would wear this flat ſide ſo deep as to ſtop the rollers, becauſe of the very ſmall ſurfaces in contact with the gudgeons. For delicate purpoſes, where hardened ſteel can be employed for all the rollers and the ring, they are a moſt admirable contrivance, and the above objections will then apply very ſlightly; but, as before mentioned, their perfection and durability will ultimately depend upon the hardneſs of the ſubſtances employed.

Fig. 16. repreſents a ſuit of friction rollers for ſupporting the weight of a heavy vertical ſhaft, as a horſe-wheel, a horizontal wind-mill, a capſtan ſugar-mill, &c. A A is a plate ſupporting the weight of the ſhaft; it has a conical eminence upon it, and a hole in the centre of this, which exactly fits the pivot or gudgeon *c*, at the bottom of the ſhaft R: upon this gudgeon a conical plate B is formed, exactly of the ſame ſhape and ſize as the conical part of the plate A, and between theſe two plates three or four rollers *a*, *a*, are ſituated, and bear the weight of the ſhaft R, or whatever preſſes upon the plate B. The rollers are kept at proper diſtances aſunder by a ring, ſhewn ſeparate at L, with three arms, *n*, projecting from it, which being formed into ſpindles, paſs through the centres of the rollers *a*, and have collets and croſs keys to keep them on. In this manner, as the gudgeon and plate B turn round, the plate rolls upon the rollers *a*, *a*, keeping always in the true centre, by the end of the gudgeon *c* fitting the hole in the centre of the plate A A; but the weight is ſupported by the rollers *a*, *a*, which, at the ſame time that the upper plate rolls upon them, they roll upon the lower, and thus very conſiderably diminiſh the friction which any other kind of gudgeon would have in ſuch a ſituation.

Shafts.—In almoſt all modern mills, the ſhafts or ſpindles for the conveyance of motion, and ſupport of wheels, are made of iron, either wrought or caſt. Square ſhafts are the moſt common, but ſometimes octagon and round ones are uſed; and if they are very large, they are caſt hollow, like pipes, and the gudgeons fixed in at the ends by wedges; but the pivots ſhould always, if poſſible, be formed of the ſame piece of metal, as the ſlighteſt poſſible deviation from the ſtraight line cauſes them to ſtrain, and work very irregularly in their bearings. In wooden ſhafts this is impracticable, and it is one of the greateſt objections to the uſe of them. The beſt method of fixing gudgeons into wooden ſhafts is ſhewn in *fig.* 17. Here A is the gudgeon, made in caſt iron, turned true; it has four leaves, *a*, *b*, *c*, *d*, forming a croſs, which is let into the end of the wooden ſhaft R: the front edge of each leaf is conſiderably thinner than the back, ſo that a pair of ſtrong iron hoops *r r* being driven tight on the end of the ſhaft, cloſes the wood round the croſs, and holds it faſt, and the back of the leaves being wider than the front, it will not come out. As an additional ſecurity, ſcrews are ſometimes put in: theſe are put through holes in the arms of the croſs, which are then made flat the other way, and do not go ſo far into the wood. The ſcrews go into the timber a conſiderable diſtance, where a mortiſe is cut into the wood, to meet the end of the bolt, and an iron nut is dropped in, to ſcrew the bolt into, when it is turned round by a ſcrew driver. By this contrivance a gudgeon may be fitted into a wooden ſhaft very faſt, but ſtill it will never come into competition with iron ſhafts, when the gudgeon is made all in one ſolid piece with the whole of the ſhaft. A judicious mechanic will never make more than two bearings upon any one ſhaft, if it can be avoided, becauſe if the three, by any means, as the warping of the frame work, or other cauſe, get the ſmalleſt poſſible quantity out of the ſtraight line, they can never work well afterwards, but will always ſtrain and wear the bearings with great friction. In very extenſive mills, ſuch as woollen and cotton mills, breweries, &c. when the buildings are of great length, it becomes neceſſary to join ſeveral ſhafts together in length, to reach from one end to the other of a mill. The manner of making the joinings is of ſome conſequence: it is neceſſary that every ſhaft ſhould have a bearing at each end, and conſequently that the connection of the ends of every one ſhould be made by uniting the ends of the ſhafts which project beyond their bearings. This can be done in various ways: one is by having the ends of each of the ſhafts provided with circular heads (ſee A B *fig.* 18.), which have teeth in one, and correſponding indentations in the other, to receive them, and thus one is made to turn the other about, at the ſame time that if any ſlight ſettlement of the building or other cauſe depreſſes one of the bearings, or raiſes another, ſo as to put the two ſhafts out of the perfect ſtraight line they ought always to preſerve; theſe joints will admit the ſlight flexure, and ſtill communicate the motion of one ſhaft to the other.

As this accidental ſettlement in large buildings is almoſt unavoidable in ſome degree, care ſhould be taken to make ſuch joints as will admit of a trifling bending. Sometimes the ends of the ſhaft are made circular, and turned quite true in the lathe; then a metal tube or collar is fitted truly upon both to cover the joint, and connect them, a bolt being put through each end, which unites both ſhafts with the collar, and thus by means of it cauſes one to turn the other round. This method is ſometimes uſed to ſave the great expence of having a bearing at each end of every length of ſhaft, one bearing to each length being then ſufficient, the other end of the ſhaft being ſupported by this collar, connecting it with the end of the adjacent length juſt where it projects beyond its bearing. But this is not a good method, as the ſhafts are apt to bend and work with ſo much friction in the bearings, if they get the leaſt out of the ſtraight line, becauſe theſe kind of joints will not admit any flexure of the ſhaft, or if they do, they will only bend on one ſide, whereas it is neceſſary for the joint to bend ſucceſſively on all ſides, when the bearings are not preciſely in a ſtraight line. *Plate* III. *fig.* 19. repreſents a coupling-box, uſed by Mr. Murray of Leeds, for connecting the lengths of a long line of ſhaft which are to carry a heavy ſtrain: it is ſo made that it will communicate the motion in the manner of an univerſal joint, if they ſhould be out of the line. Let A, B, be the two ſhafts to be united; C, D, their necks or collars which lay in the bearings: the ends projecting beyond theſe have boxes E, F, fixed on them, either by a ſquare with wedges, or by a round part with a fillet: one of theſe boxes, E, has a piece projecting from the inſide of it on each ſide, and extending into the other box, as is ſhewn at *a a*, (No. 2.), which is an inſide view: the other box, F, has two ſimilar pieces projecting from it at *b b* into the other box E: within the boxes an iron croſs *c c d d* is ſituated; it has ſcrews fixed into the ends of the croſs, and by theſe the motion is communicated: thus, the pieces *a*, *a*, when the ſhaft A and box E are turned round in the direction of the arrow (No. 2.) act againſt the ſcrews *c*, *c*, of the croſs, and turn

it

it about: at the fame time the other two ferews *d, d*, at the other arms of the crofs prefs againft the pieces *b, b*, which belong to the box F and fhaft B, thus turning them round: the crofs is placed quite detached in the boxes, and thus acts as an univerfal joint, to communicate the motion of one to the other: the ferews *c c, d d*, at the ends of the crofs are only put in that the acting points may be made of fteel, and made fmooth to have but little friction in thefe parts. Another method of uniting fhafts by Mr. Murray is fhewn at *fig.* 20: it has the advantage of requiring only one bearing for every length of fhaft, whereas the above method requires one for each end of every length. A, B, reprefent the two fhafts; each has a pivot formed at the end: thefe pivots are fitted into a coupling piece C D E, which is bored out truly to fit them infide, and the outfide turned true, with a neck D D, which is received and fitted into a bearing: the two fhafts A, B, are connected with the coupling piece D, at C and E, by means of a crofs key *l m*, put through each fhaft, and the ends of them received in notches made withinfide of the coupling piece at C and E, where it receives the ends of the fhafts. It is to be obferved that the fhafts do not fit tight in thefe parts E and C, but only in the pivots *a, b*, within, by which means they have liberty of a little motion, and this without ftraining the bearing in which D runs, becaufe it is only the fhort coupling piece which is received therein; and confequently, any trifling deviation from the ftraight line will not ftrain it, becaufe of the play allowed in the fittings.

The univerfal joint, called alfo Hooke's joint, from its inventor Dr. Hooke, is a method of uniting fhafts, which permits them to be rather inclined to each other. This is fhewn in *fig.* 21, where A, B, are the two fhafts, with necks to be received in bearings: each fhaft beyond this is formed into a fork, as C and D; and thefe are united by a crofs of iron E, or fometimes a ring, in which four pins are inferted, and pafs through holes in the ends of the forks. On one or other of thefe pins the joint will bend in any direction, on the fame principle as a compafs hangs in its gombals, and will communicate a rotative motion from one fhaft to the other, when they are rather inclined; but this inclination fhould be fmall, or elfe the joint will not act well, or without great friction, and irregularity of motion. If an angle of more than 15 degrees from the ftraight line is required, a pair of flightly bevilled wheels are beft.

The regulation of the velocity of a mill is a matter of confiderable importance, to preferve an uniformity of motion, either when the force of the firft mover is fluctuating, or when the refiftance or work of the mill varies in its degree: either or both of thefe caufes will occafion the mill to accelerate or diminifh its velocity; and in many inftances it will have a very injurious effect upon the operations of the mill. Thus, in a mill for fpinning cotton, wool, flax, &c. driven by a water-wheel, are a multiplicity of movements, many of which are occafionally difengaged, in different parts of the mill, for various purpofes. This tends to diminifh the refiftance to the firft mover, and the whole mill accelerates. Or, on the other hand, the head of water, which drives the wheel, may be liable to rife and fall fuddenly, from many caufes, which great and rapid rivers are fubject to, and caufe fimilar irregularities in the fpeed of the wheel. For fuch cafes, judicious mechanics have adopted contrivances, or regulators, which counteract all thefe caufes of irregularity; and a large mill, fo regulated, will move like a clock, with regard to its regularity of velocity. Thefe regulators are ufually termed *governors*, and are made on different principles. Thofe moft generally ufed are called flying-balls, operating by the centrifugal force of two heavy balls, which are connected and revolve with a vertical axis. *Fig.* 22. reprefents the fimpleft form of this ingenious apparatus: A A is the vertical axis, which is conftantly revolving by the machinery; at *a a* two arms or pendulums, *a b, a b*, are jointed, and carry at their extremities a heavy metal ball each, as *b b*; from the pendulums two chains or iron rods, *d, d*, proceed, and fufpend a collar *e*, which flides freely up and down the axis, and has a groove formed all round it, in which the end of a forked lever, D, is received; and thus the rifing and falling of the collar, *e*, produces a correfponding motion of the end of the lever D; but the collar is always at liberty to turn round with the axis freely within the fork, at the extremity of the lever. The operation of the governor is this: when the vertical axis is put in motion, the centrifugal force of the balls, *b, b*, caufes them to recede from the centre; and as this is done both together, they caufe the collar, *e*, and the end of the lever to rife up: the balls fly out to a certain height, and there they continue as long as the axis preferves the fame velocity; as it is the property of a pendulous ball, like *b*, to make a greater effort to return to the perpendicular, in proportion as it is removed farther from it, in confequence of the fufpending rod being more inclined, and bearing lefs of its weight. The weight of the balls to return to the axis may be confidered as a conftantly increafing quantity; while the quantity of the centrifugal force, caufing them to recede from the axis, depends exactly upon the velocity given them. But this velocity increafes as they open out, (independently of any increafed velocity of the axis,) in confequence of their defcribing a larger circle. The combination of thefe oppofitely acting forces caufes the governor to be a moft fenfible and delicate regulator. Thus: fuppofe the balls hanging perpendicular, put the axis in motion with a certain velocity, the centrifugal force will caufe the balls to fly out; and this increafing their velocity, (by putting them farther from the centre, and caufing them to revolve in a larger circle,) gives them a greater centrifugal force, which would carry them ftill farther from the centre, but for the counteracting force, *viz.* the weight of the balls tending to return. This is, as before ftated, an increafing quantity, and confequently thefe oppofite forces come to a point where they balance each other; that is, the balls fly out till their weight to return balances the centrifugal force. But if the flighteft alteration takes place in the velocity of the axis, the equilibrium is deftroyed by the increafe or diminution of the centrifugal force, and the balls alter their diftance from the centre accordingly, and by elevating or depreffing the end of the lever, operates upon fome part of the mill to rectify the caufe of the irregularity. In a fteam-engine, the lever acts upon a vane or door fituated in the paffage of the fteam from the boiler to the cylinder; and if the mill lofes in velocity, from an increafe of refiftance, the balls fall together a little; and the confequent fall of the lever opens the door or throttle valve a little wider, and gives a ftronger fupply of fteam to reftore the mill to its original velocity. On the other hand, if the mill accelerates, the balls open out and then clofe the vane, fo as to moderate the fupply of fteam. See a more full defcription of this under STEAM-*Engine*.

A water-wheel is not fo eafily regulated by the governor, becaufe the fhuttle of a large wheel requires a much greater force to raife or lower it, when the water is preffing againft it, than the lever, D, can at any time poffefs; it therefore becomes requifite to introduce fome additional machinery, which has fufficient power to move the fhuttle, and this is thrown, in or out of action, by the flying balls. The fimpleft contrivance, and that which we believe was the regulator firft ufed for a water-wheel, was erected at a cotton mill at Belper, in Derbyfhire, belonging to Mr. Strutt. A fquare

A ſquare well, or large ciſtern, was ſituated cloſe by the water-wheel: it had a pipe leading from the mill-dam into it, to admit water; and another pipe from it to the mill-tail, to take the water away: both were cloſed at pleaſure by cocks or ſluices. Within the well was a large floating cheſt, very nearly filling up the ſpace: it of courſe roſe and fell with the water in the ciſtern, and had a communication by rack and wheel-work with the machinery for drawing the ſhuttle, ſo that the rise and fall of the floating cheſt elevated and depreſſed the ſhuttle of the wheel. The lever of the governor was connected with the cocks in the two pipes, in ſuch a manner that when the mill was going at its intended velocity, both of the cocks were ſhut; but if the water-wheel went too ſlowly, the falling of the balls and deſcent of their lever, D, opened the cock in the pipe of ſupply, and, by letting water into the well, raiſed the float, and, with it, the ſhuttle, to let more water upon the wheel, till it acquired ſuch a velocity that the balls began to open out again, and thus ſhut the cock: on the other hand, if the mill went too faſt, the balls opened the pipe of exit from the well, and then the ſinking of the float cloſed the ſhuttle till the true velocity was reſtored.

Since this firſt application of the regulator to the water-wheel, the manner of its operation has been greatly varied; and as the ſame mechaniſm is applicable to any kind of mill-work, we ſhall give a ſlight ſketch of it. Suppoſe A, *fig.* 23, an axis, receiving its motion from the mill by wheel-work; it is provided with a pair of governors, *a b*, *a b*, conſtructed like thoſe before deſcribed; and at the lower part of the ſpindle is a bevilled wheel, R, turning two others, B and C, ſituated upon one ſpindle, D, which goes away, and communicates motion to the racks of the ſhuttle; the wheels, B and C, are neither of them fixed to the ſpindle D, but both ſlip round freely upon it, turning in contrary directions, as they receive motion from the oppoſite ſides of the wheel R. A locking clutch, *d*, is fitted upon the ſpindle between theſe two wheels, B, C, and can, by moving it one way or the other, be made to lock either one of the wheels to the ſpindle D, at the ſame time that it leaves the other diſengaged. The locking-box is moved by means of a lever, ſhewn in *fig.* 24; the arm *m*, having a fork to embrace a groove in the box; the lever is fixed on a vertical axis *n*, which has at the upper end two other levers, *o*, *p*: theſe lay one on each ſide of the vertical axis A, but at different heights, as is evident from the figure. The collar *e*, which is raiſed up when the balls fly out, is fitted upon a ſquare part of the ſpindle A, and is formed like a ſnail or camm, which will act upon either of the levers, *o* or *p*, according to the height at which it hangs upon its ſpindle. Now when the mill is going with its true velocity, this camm, *e*, is at ſuch a height that it is beneath one lever, *o*, and above the other, *p*, ſo as to interfere with neither; conſequently the locking-box, *d*, remains detached: but on any alteration in the velocity of the mill and the axis A, the balls open or ſhut, as before explained, and the camm, *e*, either riſes or falls, and then it preſſes againſt one of the levers, *o* or *p*, and by puſhing it away from the axis, it moves the lever *m*, and the locking-box *d*, up to one of the wheels, B or C, which it locks to the axis D, and turns it round in the direction of that wheel's motion, by which it either raiſes or depreſſes the water-wheel's ſhuttle, as is required. This apparatus may, it is plain, be applied to any other kind of mill-work.

Governors or flying-balls are very frequently uſed in the wind-mills employed for grinding flour: the variable force of this firſt mover renders ſome ſuch regulator neceſſary, to increaſe the reſiſtance, by allowing a greater feed of corn, when the mill moves too quickly, and thus in ſome degree counteracting the irregularity. If the mill moves too ſlowly, the balls tend to diminiſh the feed, and at the ſame time they raiſe the upper ſtone, to ſet them at a greater diſtance aſunder, that they may require leſs power to drive them, and conſequently ſuffer the mill, as nearly as it can, to retain its full velocity, though the motive force is greatly diminiſhed. This application of the governor was, we believe, firſt made by the ingenious captain Hooper of Margate, who invented the horizontal wind-mill. (See WIND-*Mill.*) It is a very great advantage, and no wind-mill ſhould be without them. Many wind-mills are provided with flying-balls, which, by very ingenious mechaniſm, clothe and unclothe the ſails juſt in proportion to the ſtrength of the wind.

In many mills it is of conſequence to be able to detect ſmall variations in the velocity, and to aſcertain the quantity of them; for the governor only corrects the irregularities, without ſhewing any ſcale of them. In caſes where this is required, it may be done by a very ingenious inſtrument, invented by Mr. Bryan Donkin of Fort-Place, Bermondſey. He received a gold medal from the Society of Arts, Manufactures, and Commerce, in 1810, for this inſtrument, which he calls a tachometer.

A front view of this inſtrument is repreſented in *fig.* 25, and a ſide view in *fig.* 26, of *Plate* II. X Y Z, *fig.* 25, is the vertical ſection of a wooden cup, made of box, which is drawn in elevation at X, *fig.* 26. The whiter parts of the ſection, in *fig.* 25, repreſent what is ſolid, and the dark parts what is hollow. This cup is filled with mercury up to the level L L, *fig.* 25. Into the mercury is immerſed the lower part of the upright glaſs tube A B, which is filled with coloured ſpirits of wine, and open at both ends, ſo that ſome of the mercury in the cup enters at the lower orifice, and, when every thing is at reſt, ſupports a long column of ſpirits, as repreſented in the figure. The bottom of the cup is faſtened by a ſcrew to a ſhort vertical ſpindle D, ſo that when the ſpindle is whirled round, the cup (whoſe figure is a ſolid of revolution) revolves at the ſame time round its axis, which coincides with that of the ſpindle.

In conſequence of this rotation, the mercury in the cup acquires a centrifugal force, by which its particles are thrown outwards, and that with greater intenſity, according as they are more diſtant from the axis, and according as the angular velocity is greater. Hence, on account of its fluidity, the mercury riſes higher and higher as it recedes from the axis, and conſequently ſinks in the middle of the cup; this elevation of the ſides and depreſſion in the middle increaſing always with the velocity of rotation. Now the mercury in the tube, though it does not revolve with the cup, cannot continue higher than the mercury immediately ſurrounding it, nor indeed ſo high, on account of the ſuperincumbent column of ſpirits. Thus the mercury in the tube will ſink, and conſequently the ſpirits alſo; but as that part of the tube which is within the cup is much wider than the part above it, the depreſſion of the ſpirits will be much greater than that of the mercury, being in the ſame proportion in which the ſquare of the larger diameter exceeds the ſquare of the ſmaller.

Let us now ſuppoſe, by means of a cord paſſing round a ſmall pulley F, and the wheel G or H, or in any other convenient way, the ſpindle, D, is connected with the machine whoſe velocity is to be aſcertained. In forming this connection, we muſt be careful to arrange matters, ſo that when the machine is moving at its quickeſt rate, the angular velocity of the cup ſhall not be ſo great as to depreſs the ſpirits below,

C, into

C, into the wider part of the tube. We are also, as in the figure, to have a scale of inches and tenths applied to A C, the upper and narrower part of the tube, the numeration being carried downwards from zero, which is to be placed at the point to which the column of spirit rises when the cup is at rest.

Then the instrument will be adjusted, if we mark on the scale the point to which the column of spirits is depressed when the machine is moving with the velocity required. But, as in many cases, and particularly in steam-engines, there is a continued oscillation of velocity; in those cases we have to note the two points between which the column oscillates during the most advantageous movement of the machine.

Here it is proper to observe, that the height of the column of spirits will vary with the temperature, when other circumstances are the same. On this account the scale ought to be moveable, so that, by slipping it upwards or downwards, the zero may be placed at the point which the column reaches when the cup is at rest, and thus the instrument may be adjusted to the particular temperature with the utmost facility, and with sufficient precision. The essential parts of the tachometer have now been mentioned, as well as the method of adjustment; but certain circumstances remain to be stated.

The form of the cup is adapted to render a smaller quantity of mercury sufficient than what must have been employed either with a cylindrical or hemispherical vessel. In every case two precautions are necessary to be observed. First, that when the cup is revolving with its greatest velocity, the mercury in the middle shall not sink so low as to allow any of the spirits in the tube to escape from the lower orifice; and that the mercury, when most distant from the axis, should not be thrown out of the cup. Secondly, that when the cup is at rest, the mercury shall rise so high above the lower end of the tube that it may support a column of spirits of the proper length.

Now, in order that the quantity of mercury, consistent with these conditions, may be reduced to its minimum, it is necessary, first, that if M M (*fig.* 1.) is the level of the mercury at the axis when the cup is revolving with the greatest velocity, the upper part M M X Y of the cup should be of such a form as to have the sides covered only with a thin film of the fluid; and secondly, that, for the purpose of raising the small quantity of mercury to the level L L, which may support a proper height of spirits when the cup is at rest, the cavity of the cup should be, in a great measure, occupied by the block K K, having a cylindrical perforation in the middle of it for the immersion of the tube, and leaving sufficient room within and around it for the mercury to move freely, both along the sides of the tube and of the vessel.

The block, K K, is preserved in its proper position in the cup or vessel X Y Z, by means of three narrow projecting slips or ribs, placed at equal distances around it, and is kept from rising or floating on the mercury by two or three small iron or steel pins inserted into the underside of the cover, near the aperture through which the tube passes. It would be extremely difficult, nor is it by any means important, to give to the cup the exact form which would reduce the quantity of mercury to its minimum; but we shall have a sufficient approximation, which may be executed with great precision, if the part of the cup above, M M, is made a parabolic conoid, the vertex of the generating parabola being at that point of the axis to which the mercury sinks at its lowest depression, and the dimensions of the parabola will be determined in the following manner. Let V G (*fig.* 27.) represent the axis of the cup, and V the point to which the mercury sinks at its lowest depression: at any point, G, above V, draw G H perpendicular to V G; let n be the number of revolutions which the cup is to perform in 1″, at its quickest motion; let v be the number of inches which a body would describe uniformly in 1″, with the velocity acquired in falling from rest through a height = to G V, and make $G\,H = \frac{v}{3{\cdot}14\,n}$. Then the parabola to be determined is that which has v for its vertex, V G for its axis, and G H for its ordinate: at G the cup has a lid to prevent the mercury from being thrown out of it, an event which would take place with a very moderate velocity of rotation, unless the sides were raised to an inconvenient height; but the lid, by obstructing the elevation of the sides of the cup, will diminish the depression in the middle, and, consequently, the depression of spirits in the tube: on this account, a cavity is formed in the block immediately above the level L L, where the mercury stands when the cup is at rest, and thus a receptacle is given to the fluid which would otherwise disturb the centrifugal force, and impair the sensibility of the instrument.

It will be observed, that the lower orifice of the tube is twined upwards. By these means, after the tube has been filled with spirits, by suction, and its upper orifice stopped with the finger, it may easily be conveyed to the cup, and immersed in the quicksilver, without any danger of the spirits escaping, a circumstance which otherwise it would be extremely difficult to prevent, since no part of the tube can be made capillary, consistently with that free passage to the fluids which is essentially necessary to the operation of the instrument.

We have next to attend to the method of putting the tachometer in motion, whenever we wish to examine the velocity of the machine. The pulley F, which is constantly whirling during the motion of the machine, has no connection whatever with the cup, so long as the lever, Q R, is left to itself. But when this lever is raised, the hollow cone T, which is attached to the pulley, and whirls along with it, is also raised, and, embracing a solid cone on the spindle of the cup, communicates the rotation by friction. When our observation is made, we have only to allow the lever to drop by its own weight, and the two cones will be disengaged, and the cup remain at rest.

The lever, Q R, is connected, by a vertical rod, to another lever S, having at the extremity, S, a valve, which, when the lever, Q R, is raised, and the tachometer is in motion, is lifted up from the top of the tube, so as to admit the external air upon the depression of the spirits. On the other hand, when the lever, Q R, falls, and the cup is at rest, the valve at S closes the tube, and prevents the spirits from being wasted by evaporation.

It is, lastly, to be remarked, that both the sensibility and the range of the instrument may be infinitely increased; for, on the one hand, by enlarging the proportion between the diameters of the wide and narrow parts of the tube, we enlarge, in a much higher proportion, the extent of scale corresponding to any given variation of velocity; and, on the other hand, by deepening the cup, so as to admit, when it is at rest, a greater height of mercury above the lower end of the tube, we lengthen the column of spirits which the mercury can support, and, consequently, enlarge the velocity which, with any given sensibility of the instrument, is requisite to depress the spirits to the bottom of the scale. Hence the tachometer is capable of being employed in very delicate philosophical experiments, more especially as a scale might be applied to it indicating equal increments of velocity.

velocity. But, in the present account, it is merely intended to state how it may be adapted to detect, in machinery, every deviation from the most advantageous movement.

MILLAH, in *Geography*, a mountain of Algiers; 15 miles S.W. of Tiffesh.

MILLAINS, according to Mr. Wingate, are the third subdivision of the primes in Gunter's line; and express the thousandth part of such primes.

MILLAR, John, in *Biography*, professor of law in the university of Glasgow, was born, in 1735, in the parish of Shotts, in Lanerkshire. He received his grammar education at the school of Hamilton, whence he was removed at the age of eleven to Glasgow. He was designed for the church, but the freedom of his enquiries having inspired him with a disinclination to fetter himself by subscription to articles of faith, he turned his thoughts to the bar, and his father acquiesced in the change. After he had finished his studies at Glasgow, he passed about two years in the family of lord Kames as tutor to his son, and derived much information and improvement from his connection with that eminent lawyer. At this period he contracted an acquaintance with David Hume, to whose metaphysical opinions he became a convert, though he materially differed from him upon political topics. In 1760 Mr. Millar began to practise at the bar. He was regarded as a rising young lawyer, when he thought proper to terminate his professional career by becoming a candidate for the vacant professorship of law at Glasgow. To this post he was appointed in 1761, and immediately began to execute its duties. Previously to his appointment the students of the law-course seldom exceeded four or five in number, but his reputation produced such an accession in a few years, that they frequently amounted to forty, and the pupils upon his lectures on government were much more numerous. He lectured in English, and spoke fluently with the assistance of mere notes only. By this method his lectures were rendered full of variety and animation, and at the conclusion of each he was accustomed to explain the difficulties and objections that had presented themselves to his pupils, in a free and familiar conversation. His business as professor was that of commenting upon the institutions and pandects of Justinian, but to this he subjoined a course of lectures on jurisprudence, or the general principles of law, as existing in the codes of all civilized nations: he likewise employed an hour thrice a week in lectures on government, and twice a week on the law of Scotland. A spirit of investigation had given birth to a literary society among the clergy and professors of Glasgow, of which Mr. Millar became an active member. Few men were more ready at discussions of the philosophical kind, and all the branches of science connected with the study of the human mind were extremely familiar to him. In 1771 he published a treatise on "The Origin of the Distinction of Ranks," which contained a view of the changes produced in the several relations of society by the gradual progress of civilization and improvement. It was well received by the public, and has gone through several editions. The copy now before us is one of the third edition, and was published in 1781. The treatise is divided into distinct chapters, which are subdivided into several sections, and in these subjects of much interest and great importance are discussed. The first chapter treats "Of the Rank and Condition of Women in different Ages;" the second "Of the Jurisdiction of a Father over his Children:" the third and fourth "Of the Authority of Chiefs and Sovereigns:" the fifth "Of the Changes produced in the Government of a People, by their Progress in Arts and in polished Manners:" the sixth "Of the Authority of a Master over his Servants."

Mr. professor Millar's enquiries into the English government, which made an important part of his lectures, together with a zealous attachment to the principles of liberty, led him to publish in the year 1787 the first volume of an "Historical View of the English Government," in which he traces the progressive changes in the property, the state of the people, and the government of England, from the settlement of the Saxons to the accession of the house of Stuart. This volume, which is replete with ingenious and profound speculations, would have been followed by a second, bringing down the history to the present time, had not the events which, soon after the publication of this work, passed on the theatre of Europe, so completely arrested the attention of the public, as almost to sink the importance of past forms of government, in the superior interest of those which were *expected* to arise!

Mr. Millar was an early, active, and persevering advocate for the abolition of the slave-trade, which, in his opinion, could never be palliated, far less justified, by any regulations, either respecting the transport of slaves from Africa to the West Indies, or their treatment, however mild, after their arrival. While he considered domestic slavery as the greatest curse that can befal a nation; as equally subversive of the morals of all ranks in society, he was by no means indifferent to the evils of political slavery. He viewed the attempt to tax America, as an attack on the just rights of the Colonies, and he dreaded the subjugation of that country, as a decisive step towards the overthrow of British freedom. When the French revolution, to which we have already alluded, astonished the world, he was one of those who, without entering into the wild speculations it occasioned, saw in prospect the benefits it apparently promised to Europe; and on that account hailed it as the happiest event that could have happened to the human race. To the deep regret, excited by succeeding horrors, there was, we are told, always joined in his mind, a sentiment of the most profound indignation against that coalition of continental kings, to which he thought they might be justly ascribed.

Among the parties that have divided the present reign, Mr. Millar attached himself to that of the Whigs, and particularly to that branch of them which had first the marquis of Rockingham, and afterwards Mr. Fox at their head. He always warmly supported their principles through all the vicissitudes of administration and public opinion. He was ever suspicious of power, and was a zealous friend to all attempts for restraining the increase of the power of the crown. It was probably in consequence of his jealousy of authority, that, in the limited degree in which he still followed the profession of an advocate, he made it a constant practice to appear on the circuits as counsellor for criminals; and few pleaders surpassed him in the acuteness with which he examined evidence, and the force with which he addressed the feelings of juries. Mr. Millar's researches were by no means confined to politics and law. He was an able and profound metaphysician: his acquaintance with the works of imagination, both ancient and modern was also very extensive, and his criticisms were at once ingenious and solid, evincing an admirable union of acuteness of understanding with an elegant and correct taste. He died on the 30th of May 1801, at the age of 69, leaving behind him several manuscripts, from which, in 1803, were printed, in two volumes, his posthumous works, consisting of an historical view of the English government from the accession of the house of Stuart, and some separate dissertations connected with the subject. Of the style of Mr. Millar's works, it is sufficient praise to say in the words of his biographer, that, "perhaps it would be impossible to find a sentence which can require a second perusal to be distinctly understood." Monthly Magazine, vol. ii. See also "An Account of the Life and Writings of John Millar," esq. prefixed to the fourth edition "Of the Origin of the Distinction of Ranks."

MILLARES, or MILLAS, in *Geography*, a town of Spain, in the province of Valencia, on the Xucar; 18 miles N.W. of St. Felipe.

MILLAS, a town of France, in the department of the Eastern Pyrenées, and chief place of a canton, in the district of Perpignan; 9 miles W. of Perpignan. The place contains 1361, and the canton 7029 inhabitants, on a territory of 137½ kilometres, in 9 communes.

MILLEA, in *Botany*, a genus named by Cavanilles in honour of Mr. Julian Milla, head gardener of the Royal Botanical Garden at Madrid.—Cavan. Ic. v. 2. 76. Willd. Sp. Pl. v. 2. 62.—Class and order, *Hexandria Monogynia*. Nat. Ord. *Coronariæ*, Linn. *Lilia*, Juss.

Gen. Ch. *Cal.* Perianth none. *Cor.* of one petal, funnel-shaped; tube elongated, straight; limb spreading, deeply cloven into six, ovate segments, the alternate ones narrower, and tipped with a short, hooked appendage. *Stam.* Filaments scarcely discernible; anthers six, oblong, erect and approaching each other, almost sessile, opposite to the segments of the corolla, and inserted into the upper part or throat of the tube. *Pist.* Germen superior, on a very long stalk, triangular, inclosed in the tube; style thread-shaped, prominent; stigmas three, globular, covered with thick hairs. *Peric.* Capsule oblong, triangular, of three valves and three cells. *Seeds* many in each cell, ovate, pointed, compressed into the shape of a little bag.

Obs. Cavanilles says that the germen being superior, the tube elongated and straight, the anthers nearly sessile and approaching each other, added to the deficiency of a calyx and nectary, are sufficient marks to render our present plant distinct from *Pancratium*, *Amaryllis*, *Crinum* and *Agapanthus*, to all which genera in other respects it seems to have some affinity.

Eff. Ch. Corolla funnel-shaped; with a flat limb, deeply six-cleft. Anthers inserted into the throat of the tube. Germen stalked. Capsule of three cells, with many seeds.

1. M. *biflora*. Willd. n. 1. Cavan. Ic. v. 2. t. 196.—A native of Mexico. It flowers and bears seed in the garden at Madrid in October. *Root* an ovate bulb, with very fleshy oblong fibres, covered with a thin, reddish skin. *Radical-leaves* a foot high or more, awl-shaped, sometimes furrowed on the inner side, smooth and generally longer than the scapus. *Stalks* scarcely a foot high, round, stiff, generally forked and two-flowered. *Bracteas* at the division of the stalk, three, short, acute, withering. *Corolla* white, each segment of the limb streaked at the lower part with green. *Seeds* numerous, black. The analogy of the *Tigridia Pavonia* helps us to understand this root, which Cavanilles appears to have incorrectly described.

MILLEFOLIUM, Millefoil or Yarrow, so denominated from *mille*, a thousand, in allusion to the multitude of divisions which compose its leaves. (See ACHILLEA.) The name is likewise, for the same reason, applied to an aquatic genus, called Water Millefoil. See MYRIOPHYLLUM.

MILLENARII, MILLENARIANS, in *Ecclesiastical History*, a sect among Christians, chiefly in the primitive church, who hold that Jesus Christ is to come again, and reign on earth for the space of a thousand years; during which time, the faithful are to enjoy all manner of temporal blessings; and at the expiration of this term, the day of judgment is to take place.

The Millenarii are also called *Chiliasts*, *Chiliastæ*, from the Greek χιλιας, *mille*, *a thousand*.

This opinion of the Millenarii is very ancient, and may be traced back almost as far as the time of the apostles. It had its origin from a passage in the Apocalypse too literally understood, in which mention is made of Christ's reign on earth, &c.

The opinion of S. Papias, in the second century, to whom Eusebius ascribes the origin of this notion of a millennium, says M. Launoy, touching the new kingdom of Jesus Christ on earth, after the resurrection, was held for near three centuries, before it was charged as erroneous; as appears from ecclesiastical history. It was allowed of, and followed, under various interpretations, by several of the greatest men among the primitive fathers, as Irenæus, Justin Martyr, Lactantius, Tertullian, &c. Papias, to whom this opinion is ascribed, is represented by Eusebius himself a very credulous person, and it is certain his authority deserves no implicit confidence. From the second dialogue of Justin Martyr with Trypho, we have evidence that the doctrine of the millennium had not in his time the universal reception which Mr. Gibbon the historian, with a view of serving his own purpose, has supposed. Many Christians of pure and pious principles rejected it. This appears from the testimony of Justin, in a passage which has been misunderstood by Mede and Tillotson in consequence of the substitution of ου for αυ. See Thirlby's ed. of Justin, A.D. 1722, and Jebb's ed. A.D. 1719.

Towards the close of the second century, the credit of this opinion began to decline, principally through the influence and authority of Origen, who opposed it with the greatest warmth, because it was incompatible with some of his favourite sentiments.

Nepos, an Egyptian bishop, endeavoured to restore this opinion to its former credit, in a book written "against the Allegorists," for so he called, by way of contempt, the adversaries of the millenarian system. But Dionysius of Alexandria, a disciple of Origen, stopped the growing progress of this doctrine by his private discourse, and also by two learned and judicious dissertations concerning the "divine promises." Jerom is also said to have opposed this millenary reign of Christ. The ancient Millenarians generally held, according to the account of the learned Dr. Whitby, that the temple, or the city of Jerusalem, should be rebuilt, and that the land of Judea should be the habitation of those risen saints, who were to reign on earth a thousand years; that this resurrection was not to be confined to the martyrs only, but that all the just were then to rise and reign with Christ; and that this reign should also extend to the just who were found alive at this first resurrection; that Jesus Christ shall then come down from heaven, and be seen on earth, and there reign with his servants; and that they shall then fare deliciously, and enjoy the richest wines and most delicious fruits, build houses, plant vineyards, and eat the fruits of them, and propagate their species.

Dr. Whitby has clearly proved, that this opinion of the millennium was never generally received in the Christian church, and that there is no just ground to think it was derived from the apostles. Indeed, if we examine their writings critically and candidly, we shall find that they never predicted this event to others, nor cherished the expectation of it in themselves. The passages which seem to countenance this opinion are contradicted by others, which are altogether inconsistent with it; so that the apostles never entertained the delightful hope of seeing their master coming again into the world. It is evident that St. John, who survived all the other apostles, could not have had any such expectation; since in the book of the Revelation the future events of the Christian church, which were not to take place, many

many of them, till a long period of years after his death, and some of which have not yet been accomplished, are there minutely described. St. Peter likewise strongly intimates, that the day of the Lord might be said to be at hand, though it was at the distance of a thousand years, or more. St. Paul, in his second epistle to the Thessalonians, labours to remove the erroneous opinion that had been adopted by some, who expected the speedy coming of Christ; he describes a great corruption of the Christian church, which was to happen before the day of the Lord, and this appears by the express language of his prophecy to comprehend circumstances, which did not occur till many ages after they were predicted. But allowing, says bishop Watson, that the apostles did expect that Christ would come in their own time, their mistake in this respect ought not in anywise to diminish their authority as preachers of the gospel. They might be proper witnesses of the life and resurrection of Christ, though they were not acquainted with every thing which might have been known, though, in particular, they were ignorant of the precise time when our Lord would come to judge the world. It can be no impeachment, either of their integrity as men, or their ability as historians, or their honesty as preachers of the gospel, that they were unacquainted with what had never been revealed to them; that they followed their own understandings, where they had no better light to guide them; speaking from conjecture, when they could not speak from certainty; of themselves, when they had no commandment of the Lord. There is therefore no ground for the reflections of Mr. Gibbon, tending to invalidate the truth of Christianity and the doctrine of a future state, and founded on what he conceives to have been the opinion of the apostles and of ancient Christian writers, concerning the millennium. Watson's Apology for Christianity.

The millennium, according to the learned commentator Dr. Whitby, is a glorious state of the church, commencing after the fall of antichrist; and the subsequent conversion of the Jews to the Christian faith, in which it shall flourish in peace and plenty, in righteousness and holiness, and in a pious offspring, for a thousand years, under the undisturbed, though not personal government of Christ, over both Jews and Gentiles, which shall then be united into one church.

MILLENBACH, or MILBACH, in *Geography*, a town of Transylvania; 20 miles W. of Hermanstadt. N. lat. 46° 6'. E. long. 23° 14'.

MILLENNIUM, compounded of *mille, a thousand*, and *annus, a year*, a term literally signifying a *thousand years;* chiefly used for the time of our Saviour's expected second appearance, and reign on earth.

Mr. Whiston, in several of his writings, has endeavoured to support the notion of a millennium. According to his computation it was to have commenced about the year 1720. See MILLENARII.

MILLEPEDA, in *Conchology*, the name given by authors to a species of *Strombus*; which see.

MILLEPEDES, or SLATERS, in *Zoology*, well known insects, formerly used on many occasions in medicine. This insect is otherwise called *asellus*, being a species of *oniscus*, in English the *wood-louse*. (See ASELLUS and ONISCUS.) Mr. Ray describes seven different species of this insect, some of which we see every day, others are more rare. The blue kind, which rolls itself up into a ball, is the proper medicinal kind; though there is another sort of a pale brownish-grey, smaller, flatter, and thinner than the former, and having the last division of the body not annular but pointed, and a forked tail, which is of the same quality. They are found in cellars, on roofs of houses, old walls, and under stones and logs of wood in cold moist places. They are rather more than half an inch in length, whitish on the belly, with seven pairs of legs, each terminated by a sharp horny claw. The head is somewhat pyramidal, and furnished with two articulated feelers; and the upper part is guarded by a callous, brownish, livid-coloured, jointed armour, consisting of 14 semicircular slates, within which the insect rolls itself like a ball when touched; like some other insects it casts the skin, and carries the young in valvular follicles under the abdomen.

Millepedes are so generally known among the vulgar, that most persons seem to be masters of their medicinal uses, and take them in many cases without any other direction. They were formerly regarded as expectorant, diuretic, and abstersive, and occurred frequently in prescriptions for disorders in the kidnies, and also in obstructions of the viscera, and particularly in the jaundice; and in many other diseases. Although they are retained in the list of Materia Medica, the good sense of modern practitioners has nearly exploded the use of them.

The *millepedes præparatæ* of the shops, when they were considered as a medicine of importance and beneficial efficacy, were reduced to powder, either by inclosing them in a thin canvas cloth, and suspending them over hot spirit of wine in a close vessel, till they were killed by the steam and rendered friable; or by including them in a proper vessel and drying them with a very gentle heat. The prepared millepedes, or slaters as they are called, have a fetid odour, and a sweetish nauseous taste.

There were also several chemical preparations of millepedes, as spirit, volatile salt, oil, and wine of millepedes.

The college of Edinburgh formerly directed two ounces of live millepedes to be slightly bruised, and digested for a night in a pint of Rhenish wine, after which the liquor is to be pressed through a strainer.

MILLEPORA, in *Natural History*, a genus of the class Vermes, and order Zoophyta. The animal is an hydra or polype; coral mostly branched, and covered with cylindrical turbinate pores. There are 34 species, chiefly inhabitants of the Mediterranean: but some are found on our own coasts, especially in Cornwall, and a few are scattered through the seas of America, India, and Polynesia.

Species.

ALCICORNIS. This species is branched, compressed, straight, with scattered and scarcely visible pores. It inhabits the Indian and American seas, and is frequently found incrusting pieces of rock, gorgonia, and cocoa-nuts; dull white with sometimes a yellowish tinge, smooth, solid, stony, sometimes brittle, with very minute pores.

CÆRULEA. This is flat, rough, divided into thick plates bending different ways, the tops of which are sometimes lobed, and both sides furnished with cylindrical substellate pores. It is found in vast masses in the Indian ocean; the laminæ or plates are generally half an inch thick, and full of minute pores between the star-like cells. It appears to be an intermediate species between the madrepores and the millepores.

ASPERA. Somewhat compressed, with eminent pores, which are sometimes cleft. It inhabits the Mediterranean seas. It is erect, pointing two ways, roundish, with crowded pores at the branches, cleft on the lower side.

SOLIDA. Turbinate, with crowded angular pores. Found on the shores of Gothland. Tubes of pores with transverse divisions within.

TRUNCATA. Dichotomous, erect, with truncate branches. It

It inhabits the Mediterranean and North seas. Is of a yellowish-grey colour, and appearing as if covered with a coat of varnish, very brittle, within greyish, the branches are divaricate, the pores are placed in a quincunx order.

MINIACEA. Very minute, branching into small lobes, and covered with small pores. This species is found in the Mediterranean and Indian seas. It is a beautiful little coral, and the smallest of its genus, being seldom above a quarter of an inch high; the whole surface, when magnified, appears full of minute, white, blind spiracles, and on the tops of the lobes are several scattered holes surmounted with a margin; the base is broad, and with this it adheres to shells, rocks, and other corals.

* CERVICORNIS. This is a little compressed, dichotomous, with cells on both sides, tubular, and prominent florets. It inhabits the Mediterranean and Cornish coasts; is from five to six inches high; is of reddish or yellowish-brown, within whitish, branched like the horns of a stag, and appearing as if covered with a varnish; a few of the pores are divided at the base, which are narrow, and of a brittle texture.

* SKENEI. Compressed, and slightly branched, with cells on both sides, disposed in alternate rows; cells turbinate, with a gaping mouth and covered with a helmet, the under lip furnished with a small tooth. It is found near Aberdeen, adhering to the rocks; of a bright shining white colour, and appearing as if covered with silver varnish.

PUMILA. This is depressed, with scattered irregular retuse branches every where porous and roughish. It inhabits the Mediterranean, on shells and rocks; is about three inches high, solid, and very much branched, pale grey, and within whitish.

COMPRESSA. This species is furnished with a stem slightly branched, and a little compressed, branches distant, pores every where a little prominent and rough. It inhabits the Mediterranean.

* LICHENOIDES. Caulescent, decumbent, with waved nearly opposite denticulate branches; pores a little prominent on the upper side, and striate beneath. It inhabits the Mediterranean and European coasts, on stones and other marine substances; milk-white, very brittle, and about two inches long.

VIOLACEA. Flat, branching, with erect flexuous round branches, a little compressed, with a porous suture encompassing the margin. It inhabits the South-sea islands; is about three inches high; fine violet blue, with two rows of small pores each side the margin, besides the line of larger ones surrounding it; the surface is rough with a few clusters of little studs.

TUBULIFERA. This species is solid, branched, with tubular scattered pores; the branches are confluent, with tapering rough extremities. It inhabits the Sicilian seas; is about four inches high, white, solid; the trunk and branches smooth.

* FASCIALIS. Membranaceous, flat, narrow, branched, flexuous, with pores on both sides. It is found on the coast of the Isle of Wight, as well as in the Mediterranean, and grows in irregular masses; the branches are flat, narrow, and irregularly subdivided, which coalesce, twist, and branch out again, leaving hollow spaces between them. It is about six inches in diameter.

* FOLIACEA. This is, as its name imports, foliaceous, flexuous, uniting sometimes at the extremities, and is covered with pores on both surfaces, so small as to be scarcely visible. Found growing to an oyster-shell at the Isle of Wight; is from three to twelve inches long, white and stony.

ZEYLANICA. This is composed of thin concrescent irregularly divided membranes, with rows of oblong cells on each side. It is of a white colour, and is found in the Indian ocean.

FORNICULOSA. Crustaceous, with rows of vaulted cells furnished with a small ringent lip, and closed by a membrane. Is found in South America, adhering to other corallines; resembles the Flustra foliacea, and is thought by some to be a cellepore.

CRUSTULENTA. Crustaceous, somewhat branching, and irregularly shaped, with rows of oblong cells closed by a membrane, and very entire divisions. It inhabits the salt dykes of Holland, and the Atlantic; is of a greyish-white colour, and forming sub-globular masses.

EROSA. This also is crustaceous, with open cells pectinate at the lateral margin. It is found in the American ocean, affixed to rocks; the cells have erect subulate teeth, about four on each side.

RETICULATA. Membranaceous, with depressed linear branches rough on the upper surface, with prominent pores. It inhabits the Mediterranean and West Indies; is white, brittle, horizontal, convolute, and much branched; the reticulate branches growing in an undulate manner, and coalescing occasionally; the upper surface is rough, with pointed pores, the under surface is striate.

* CELLULOSA. Membranaceous, reticulate, funnel-formed, irregularly waved, and plaited at the margin, with numerous pores on one side. It is found in the Mediterranean and European seas, fixed to marine substances, and resembles a piece of lace, consisting of a flat erect undulated membrane covered with large regular perforations, sometimes disposed in a cup-shaped form, at other times running into loose folds with a waved margin like a ruffle; is about three inches high, solid, brittle, white or yellowish-grey, with very vivacious polypes.

CLATHRATA. Umbilicate, reticulate, with flat branches that are porous on one surface. It inhabits the Indian ocean, and is thought to be an intermediate species between the Cellulosa and Lichenoides; it is white and seated on a solid centre.

RETICULUM. Composed of branched cancellate threads. It is found in the Mediterranean, covering the surface of shells and the roots of fuci; resembles a spider's web, and is composed of fine capillary threads.

SPONGITES. Caulescent, erect, with angular imbricate branches; it resembles a sponge; is about a foot long: the pores are not visible.

CORIACEA. Sub-membranaceous, semi-orbicular, and nearly horizontal, with a few pores on the lower surface. It inhabits the Atlantic and Numidian seas, covering the stems of the Fucus cartilagineus, and forming covers for the chambers of other corals.

CALCAREA. Branched, milk-white, solid, with tapering sub-divisions. It inhabits the Mediterranean; is four inches high. The branches grow smaller towards the end, and are usually regularly sub-divided.

* POLYMORPHA. Crustaceous, solid, irregularly shaped, but generally branched and tuberculate, and without visible pores. This is found in most of the European seas, and is the common coral of the shops: in many places it grows in such abundance, that it is burnt for manure; its colour is either red, yellowish, or greenish, and is but seldom white! It was formerly much used in medicine as an absorbent. It is sometimes shaped like the kernel of a walnut, often in large compressed masses, sometimes like a small bunch of grapes, but most frequently in short and rather irregular

 ramifications

ramifications of a chalky tuberculate appearance, and ftony fubftance.

Decussata. Compofed of cretaceous erect laminæ, or plates, croffing one another, and uniting differently in different places. It is found on the coaft of Portugal, in maffes about five or fix inches wide.

* Alga. This confifts of thin femicircular plates, difpofed horizontally: it inhabits the Cornifh coaft, adhering to and frequently entirely covering the Polymorpha, and is either red, purplifh, yellow, or whitifh; extremely thin and brittle, with femicircular plates of various fizes, conftantly growing horizontally, with their margins bending over, rendering them convex on the upper fide, and concave beneath.

* Pumicosa. Irregularly fhaped, brittle, rough, and compofed of fharp-pointed roundifh cells. It inhabits the Britifh coafts, and is frequently found incrufting many of the Sertularia in fmall irregular maffes, appearing very like white fand ftrongly united together; the branches are generally cylindrical, each about half an inch long; the cells are placed round about in alternate order, fhaped like an helmet juft opening, with a hole in the middle.

* Tubulosa. This is a parafitic plant, cruftaceous, pale purple, with fmall tubular cells difpofed in tranfverfe rows or whorls. It inhabits the Mediterranean and Britifh coafts, and is found frequently encompaffing the ftem of the Sertularia falcata.

Pinnata. Dichotomous, erect, with tubular pores difpofed in a pinnate order. Inhabits the Mediterranean: when frefh caught it is greyifh, though fometimes green, is about an inch high, and very brittle.

* Liliacea. Creeping proftrate, in obtufe linear divifions, with tubular pores on the upper furface difpofed in tranfverfe rows. It inhabits the Mediterranean and Cornifh coafts, and refembles, in fome refpects, the Tubulofa, but is white.

Carduncculus. This is irregularly fhaped, membranaceous, with concentric wrinkles, and central triangular pyramidal tubes. It is found in the Mediterranean, adhering to the Sertularia; it is minute, white, fub-pellucid, and refembling the flower of a thiftle.

MILLER, Philip, in *Biography*, a celebrated gardener and botanift, was born in 1691. His father had the fuperintendance of the Phyfic Garden at Chelfea, belonging to the Apothecaries' Company, and founded by fir Hans Sloane; to which appointment he himfelf fucceeded in the year 1722. In this fituation he became diftinguifhed by his practical knowledge of plants, and efpecially by his fkill in their cultivation. The latter was evinced in a paper, communicated by himfelf to the Royal Society in 1728, and printed in the 35th volume of the Philofophical Tranfactions, on "a method of raifing fome exotic feeds," which had been judged almoft impoffible to be raifed in England. This confifted in allowing them to germinate in a bark bed, previoufly to their being planted in earth. By this means alone, feveral hard-fhelled nuts can be made to vegetate in our ftoves; and indeed the practice is founded on a judicious obfervation of nature's operations. Two years afterwards, Mr. Miller made known, for the firft time, the prefent popular mode of caufing bulbous plants to flower in water.

In 1730 he publifhed anonymoufly a thin folio, accompanied with twenty-one coloured plates, after the drawings of Van Huyfum, entitled "A Catalogue of trees, fhrubs, plants, and flowers, both exotic and domeftic, which are prepared for fale in the gardens near London." The preface is figned by a fociety of gardeners, amongft whom the name of Miller appears. The work is much more than a mere catalogue, the generic characters being given in Englifh, and many horticultural and economical remarks fubjoined. Moft of the plates contain figures of feveral different plants. This publication is mentioned by Haller, who was uninformed refpecting its real author, in his *Bibl. Bot.* v. 2. 229.

In 1731 appeared the firft edition of the "Gardener's Dictionary," in folio, the moft celebrated work of its kind, which has been tranflated, copied and abridged, at various times, and may be faid to have laid the foundation of all the horticultural tafte and knowledge in Europe. It went through eight editions in England, during the life of the author, the laft being dated 1768. This forms a very thick folio volume, and follows the nomenclature and ftyle of Linnæus; the earlier ones having been written on Tournefortian principles. A much more ample edition has been publifhed within a few years, making four large volumes, under the care of the Rev. Prof. Martyn. In this all the modern botanical difcoveries are incorporated with the fubftance of the 8th edition. Linnæus has juftly remarked, that Miller's was a botanical as well as a horticultural dictionary. We cannot but think that it has proved a powerful means of introducing a tafte for fcientific botany, amongft thofe who at firft had recourfe to it merely as cultivators.

This work had been preceded, in 1724, by an octavo of two volumes, called "The Gardener's and Florift's Dictionary," and was foon followed by "The Gardener's Kalender," a fingle octavo volume, which has gone through numerous editions. One of thefe, in 1761, was firft accompanied by "a fhort introduction to a knowledge of the Science of Botany," with five plates, illuftrative of the Linnæan fyftem. Miller had been trained in the fchools of Tournefort and of Ray, and had been perfonally acquainted with the great Englifh naturalift, of which he was always very proud. No wonder therefore if he proved flow in fubmitting to the Linnæan reformation and revolution, efpecially as fir Hans Sloane, the Mecænas of Chelfea, had not given them the fanction of his approbation. At length more intelligent advifers, Dr. Watfon and Mr. Hudfon, overcame his reluctance, and, his eyes being once opened, he was no longer behind-hand in deriving advantage from fo rich a fource. He became a correfpondent of Linnæus, and one of his warmeft admirers. Although it does not appear that he had any direct communication with Micheli, he was chofen a member of the Botanical Society of Florence, which feems to indicate that they were known to each other, and probably communicated through Sloane and Sherard, as neither was acquainted with the other's language. Miller maintained an extenfive communication of feeds with all parts of the world. His friend Houfton fent him many rarities from the Weft Indies, and Miller but too foon inherited the papers of this ingenious man, amongft which were fome botanical engravings on copper. Of thefe he fent an impreffion to Linnæus; and fuch of them as efcaped accidents, afterwards compofed the *Reliquiæ Houftonianæ.* See Houstonia.

In 1755 our author began to publifh, in folio numbers, his "Figures of Plants," adapted to his dictionary. Thefe extended to three hundred coloured plates, making, with defcriptions and remarks, two folio volumes, and were completed in 1760. They comprehend many rare and beautiful fpecies, there exhibited for the firft time. The commendable defign of the writer was to give one or more of the fpecies of each known genus, all from living plants; which as far as poffible he accomplifhed. His plates have more botanical diffections than any that had previoufly appeared in this country.

Miller was a fellow of the Royal Society, and enriched its Tranfactions

Tranfactions with feveral papers. The moft numerous of thefe were catalogues of the annual collections of fifty plants, which were required to be fent to that learned body, from Chelfea garden, by the rules of its foundation. Thefe collections are preferved in the Britifh Mufeum, and are occafionally reforted to for critical enquiries in botany. He wrote alfo on the Poifon Afh, or *Toxicodendrum*, of America, which he believed to be the Japanefe Varnifh tree of Kæmpfer; a pofition controverted by Mr. Ellis. (See Ellis.) The latter appears to have been moft in the right, which may account for a certain degree of ill humour betrayed by Mr. Miller in the courfe of the difpute. It is fcarcely confiftent with the ufual candour of the amiable Dr. Pulteney, that in his "Sketches of the Progrefs of Botany in England," he rather difcovers a partiality to Miller on this fubject. We cannot account for his omitting all account of fo great a man as Ellis, in that valuable work.

Miller continued to attend to his duties and his favourite purfuits to an advanced age, but was obliged at length, by his infirmities, to refign the charge of the garden. He died foon after, at Chelfea, December 18, 1771, in his 81ft year, and was interred in the burying-ground in the King's road, with his wife, by whom he had, if we miftake not, feveral children. One of them, Mr. Charles Miller, fpent fome time in the Eaft Indies, where he acquired a handfome fortune, and is, we believe, now living in England. This gentleman made fome experiments on the cultivation of wheat, an account of which was given by Dr. Watfon to the Royal Society. They were intended to fhew the wonderful produce to be obtained by divifion and tranfplantation, and have often been repeated. An account of the ifland of Sumatra, by Mr. C. Miller, is printed in vol. 68th of the Philofophical Tranfactions. The fifter of Philip Miller married Ehret, and left one fon. See Ehretia.

In the courfe of his refidence at Chelfea, Miller collected, principally from the garden, an ample herbarium, which was purchafed by fir Jofeph Banks. He fent many dried fpecimens to Linnæus. Pulteney's Sketches. Haller Bibl. Bot. Works of Miller. Dryandr. Bibl. Banks.

Miller, James, an Englifh dramatic writer, was born in the year 1703. He was defigned for bufinefs, and received an education fuitable to it, but feeling a repugnance to that fort of employment he went to Wadham college, Oxford, and having completed the ufual courfe he took orders. While at the univerfity he wrote a famous comedy, entitled "The Humours of Oxford," which was performed in 1729. He was author of feveral other pieces, of which the laft was a tragedy, entitled "Mahomet." This had a confiderable run, and before its popularity was at all abated, the author died in 1743. He publifhed a volume of fermons, and poems. Biog. Dram.

Miller, *Lady*, an accomplifhed woman, of fome literary talents, who publifhed letters from Italy, fix vols. 8vo. She refided at Bath-Eafton, near Bath, where fhe entertained feveral ingenious perfons, who compofed a collection of poems, which was afterwards publifhed. She died in 1781.

Miller, an admirable performer on the baffoon, who flourifhed in the middle of the laft century. The concertos which he performed during many years, at Vauxhall, Hickford's Room, the Swan, Caftle, and King's Arms concerts, and the folo parts allotted him by Handel in his oratorios and concertos, always excited attention, were heard with delight, and juftly applauded for the fweetnefs of his tone, and neatnefs of his execution.

Miller's, in *Geography*, a fettlement in Kentucky, on a branch of Licking river; 32 miles N.E. of Lexington.

Miller's *Bay*, a bay on the S. coaft of Jamaica, N. of Portland Point.

Miller's *Town*, a town of Northampton county, in Pennfylvania, pleafantly fituated on a branch of Little Lehigh river; 47 miles N.W. by N. of Philadelphia; containing about 40 houfes.—Alfo, a town in Shenandoah county, in Virginia; 32 miles S. of Winchefter.

Miller's *Thumb*, in *Ichthyology*, an Englifh name for the fifh called alfo the bull-head, and by authors the cottus; being the Cottus *gobio* of Linnæus; which fee.

MILLERIA, in *Botany*, received its name from Dr. Houfton, and was firft publifhed by Prof. Martyn, fen., in honour of their common friend, the celebrated curator of Chelfea garden. (See Miller.) Linnæus, in adopting the name, obferves, *Crit. Bot.* 80, that "this American plant, whofe clofe-fhut calyx entirely furrounds and protects its one or two feeds, is well beftowed on a man who fpared no pains in procuring rare American feeds, and in contrivances for preferving and communicating them."—Linn. Gen. 443. Schreb. 579. Willd. Sp. Pl. v. 3. 2328. Mart. Mill. Dict. v. 3. Ait. Hort. Kew. ed. 1. v. 3. 266. Juff. 187. Lamarck Illuftr. t. 710. Gærtn. t. 168. Houft. Ic. ined. f. 13. (Randia; ibid. f. 14.)—Clafs and order, *Syngenefia Polygamia-neceffaria*. Nat. Ord. *Compofitæ oppofitifoliæ*, Linn. *Corymbiferæ*, Juff.

Gen. Ch. *Common Calyx* of one leaf, very large, in three deep fegments, clofed together in a flattifh-triangular form, permanent; the two *innermoft* equal, nearly ovate, acute, flat; the *outer* one twice as large, roundifh, pointed, flat, heart-fhaped at the bafe, moft deeply feparated. *Cor.* compound, half radiant: *united florets* two, within the fmaller fegments of the calyx: *female* folitary, within the larger one: the former of one tubular, erect, five-toothed petal: the latter ligulate, erect, obtufe, concave, with one or two notches. *Stam.* (in the united florets) Filaments five, capillary; anthers as many, erect, linear, connected laterally by the middle, acute, as long as the corolla. *Pift.* (in the fame) Germen oblong, very thin; ftyle thread-fhaped, the length of the petal; ftigmas two, linear, weak, obtufe, fpreading: (in the female floret) Germen large, triangular; ftyle thread-fhaped, the length of the petal; ftigmas two, briftle-fhaped, long, reflexed. *Peric.* none, except the clofed common calyx, become coriaceous and coloured. *Seed* to the united florets none: in the female ones folitary, oblong, obtufe, triangular, tapering downward. *Down* none. *Receptacle* very minute, naked.

Obf. *M. quinqueflora* has the female floret three-cleft; the united ones four in number; calyx accompanied by five membranous internal leaves; ftyle fimple in the united florets, cloven in the female.

Eff. Ch. Receptacle naked. Down none. Common Calyx of three permanent valves. Corolla femi-radiant.

1. M. *quinqueflora*. Five-flowered Milleria. Linn. Sp. Pl. 1301. Mant. 478. (M. dichotoma; Cavan. Ic. v. 1. 58. t. 82. M. annua erecta, foliis conjugatis, floribus fpicatis luteis; Mart. Decad. 41. t. 41.)

β. M. *maculata*. Mill. Dict. ed. 8. n. 2. (M. annua erecta ramofior, foliis maculatis, profundiùs ferratis; Mart. Decad. 47. t. 47. f. 2.)

Leaves heart-fhaped. Flower-ftalks forked. Calyx double.—Native of Vera Cruz, Panama and Mexico. Sent to Chelfea garden in 1731 by Houfton, but now loft, having no beauty to fecure the attention of cultivators in general. Linnæus had it at Upfal, and Cavanilles at Madrid. This is an annual ftove plant, flowering in autumn. *Stem* five or fix feet high, fquare, branched, leafy. *Leaves* oppofite, ftalked, heart-fhaped, broad, ribbed, roughifh, flightly toothed

toothed or serrated, tapering at the base. *Flowers* small, yellow, in terminal, leafy, slender, forked panicles. The *leaves* of the variety β are more strongly serrated, of a darker green, and blotched with black. The number of *florets* varies.

2. M. *biflora*. Two-flowered Milleria. Linn. Sp. Pl. 1301. Hort. Cliff. t. 25. (M. annua erecta minor, foliis parietariæ, floribus ex foliorum alis; Mart. Decad. 47. t. 47. f. 1.)—Leaves ovate. Flower-stalks simple, terminal, aggregate. Calyx single.—Native of the country near Campeachy, from whence it was sent by Houston in 1730.—Rather smaller, and less showy than even the former. The *leaves* are ovate and triple-ribbed. *Flowers* pale yellow, very small, in terminal tufts.

Willdenow's *M. Contrayerba*, n. 3. Cavan. Ic. v. 1, 2. t. 4, is our *Flaveria capitata* (see FLAVERIA); and his *angustifolia*, n. 4. Cavan. Ic. v. 3. 12. t. 223, is of the same genus. Perhaps *Flaveria* ought to be sunk in *Milleria*, Cavanilles having found a radiant floret. Their habits however are not similar. S.

MILLE-ROCHES, ISLE AU, in *Geography*, a small island of Upper Canada, in the river St. Laurence, containing from 6 to 700 acres of good soil. N. lat. 45° 5′. W. long. 75° 40′.

MILLEROLLE, in *Commerce*, an oil measure at Marseilles = 4 escandaux = 64 Paris pintes, or $15\frac{3}{4}$ English gallons nearly, and weighing about 136 poids de table, or 122lb. avoirdupois. The wine measure of the same denomination is = 4 escandaux = 60 pots; and 4 millerolles of wine = 63 English gallons nearly; and $3\frac{1}{2}$ millerolles are reckoned = a Bourdeaux hogshead.

MILLERS, or PAYQUAGE, in *Geography*, a river of the Massachusetts, which runs W. by S. and falls into Connecticut river, between Northfield and Montague.

MILLERY, a town of France, in the department of the Rhône and Loire; seven miles S. of Lyons.

MILLES, JEREMIAH, in *Biography*, a learned divine and antiquary, was born at High Cleer, in Hampshire, in 1713, of which place his father was minister. He succeeded Dr. Lyttleton as dean of Exeter, and also as president of the Society of Antiquaries, to whose Archæologia he was a great contributor. Dr. Milles was a zealous champion for the genuineness of the Rowley poems, of which he printed an edition in 4to., with glossarial annotations. This work laid him open to the attacks of the critics, who were sceptical on these supposed relics of antiquity. The dean died in 1784.

MILLESSOW, in *Geography*, a mountain of Bohemia, in the circle of Leitmeritz.

MILLET, in *Botany*. See MILIUM.

MILLET, the common name of a plant which grows naturally in India, whence it was first imported into Europe. It is greatly cultivated in Italy, Spain, and the southern parts of France, for the food of men as well as that of poultry. It may also be raised in this climate. This is a plant that delights in a light sandy soil, prepared in the same manner as for maize; and in such lands it branches out into many stalks, sometimes thirty or forty, not unlike reeds either in their shape or leaves, of which there is one at each joint. The top of each stalk is terminated by a large, loose panicle, which hangs on one side, with a chaffy flower, which is succeeded by a small round seed, about the bigness of turnip or cabbage seed, of a yellowish-white colour in one variety, and of a dark red inclining to black in another, which are the small millet, and the large, a distinction which some make, as only varieties of the same species. It is likewise said to thrive extremely well in strong land; but will not do in stony ground, or where the bottom is of either a chalky or clayey nature.

Miller advises, that it should be sown in the beginning of April, that it may ripen in August; but in warmer climates, the general rule is to sow it either between the middle and the end of May, or about Midsummer. The former crop is reaped at the end of September, and the latter about the end of October. The seed is usually sown in furrows, very thin, and covered with the plough or rake. The largest sort should be sown thinnest, because it branches most. When the plants are about a month old, the ground should be stirred round them with a hand-hoe, as well to lay fresh earth to their roots, as they require much nourishment, as to clear them from weeds, which they afterwards prevent by over-topping them. At the same time, the millet plants should be thinned out wherever they grow too close, so as to leave, in general, about six inches between each plant. Nothing more is necessary to be done till harvest, except that, when it begins to ripen, great care must be taken to protect it from birds, which would otherwise soon devour it. The returns of this crop are very great; it is not easily hurt by drought or rain, nor is it subject to blight. Frequent showers of rain are of great service to it whilst in its young growth.

As soon as the crops are ripe, the panicles of the plants are cut off near the uppermost joints of the stalks with a knife, and put into baskets or sacks, in which they are carried home, when they are then laid up in heaps covered with old cloths, and after remaining in that situation five or six days, spread upon the barn floor, threshed out with a flail, and cleansed like other sorts of grain. Great care must be taken to dry it well in the sun, before it is laid up in the granary; as it soon spoils if the least moisture be left in it; being of all grains the most difficult to keep, unless it be thoroughly dry; but on the other hand, none keeps longer, or better, after it has been well dried. It is not liable to the weevil; but it should be turned from time to time in the granary. It has been constantly found that the late sown crops are the most defective, and that their panicles are smaller than those of the same grain sown at an earlier period.

But the small white millet is the most delicate, and the best for puddings, &c. The red is larger and coarser, and used for pigeons, poultry, and swine, after being ground to meal; it is very good fodder for cattle, either green or after its grain is threshed out. From its numerous roots, large size, and quick growth, it is a sort of crop that exhausts the soil greatly, and of course must be well guarded against in that respect.

The common millet was originally brought from the eastern countries, where it is still greatly cultivated: from whence we are furnished annually with this grain, which is by many persons greatly esteemed for puddings, &c. This is seldom cultivated in England, but as a curiosity in small gardens, or for poultry, as its seeds generally ripen well.

Millet is reckoned by Pliny the most fertile of all grain; one grain of it producing three Roman sextaries.

Millet is cooling, drying, and binding, somewhat windy, and not easily digested; a strong decoction of it with figs and raisins, mixed with wine, and drank warm in bed, is a very good sudorific, though it is seldom used.

Millet, by consent of authors both ancient and modern, is refrigerating and drying; it is of bad juice, difficult of digestion, binds the belly, and generates flatulencies; it is however well known to be a very grateful food to many nations at present. In former times it served to make bread, under a dearth of better corn, as we are assured by Dioscorides,

corides, Pliny, Galen, and others of the ancients. Among the Italians, says C. Bauhine, loaves are made of millet, which are yellow, and eaten hot by many, not out of necessity, but for their sweetness; but when this bread is grown hard, it is quite black. Of the flour of millet and milk, the Italians make fine cakes, which must be eaten as soon as dressed, or else they become glutinous, and ungrateful to the taste.

A pudding prepared of millet, boiled in milk, with an addition of butter, and sugar sprinkled over it, is much in request among the Germans at present; and these puddings have been long ago introduced into England, and are still in fashion.

The flour of millet was formerly used in fomentations, for the gripes, and for pains of the head and nerves; it was applied externally in bags, because the use of it in cataplasms was difficult, on account of its friability. If the membrane of the brain happens to be wounded, it is excellently conglutinated, says Archigenes, by infusing thereon the juice of calaminth, and sprinkling it with dry flour of millet. A decoction of millet, with figs and raisins, is called, by Heurnius, a noble sudorific and diuretic. Or, take of a decoction of millet, boiled till it bursts, four ounces; white wine, two ounces: let the patient take it hot. Chesneau.

Millet is diuretic and astringent; the seeds are of extraordinary service in diseases of the lungs, and exulcerations of the kidnies: made into a cataplasm, they are anodyne and resolvent. Hist. Plant. adscript. Boerhaave.

MILLET, *Indian*. See HOLCUS.

MILLEVANT, in *Geography*, a town of Prussia, in the province of Pomerelia; 16 miles S.S.E. of Dantzic.

MILLEVILLE, ALESSANDRO, in *Biography*, an excellent organist, born at Ferrara, much celebrated in Italy at the beginning of the seventeenth century. He was successively patronized by the king of Poland, the emperor of Germany, and the duke of Ferrara. He was also a voluminous composer, as appears by all the catalogues of the time; in which we find the following list of his works: Messe e Salmi a 3 voci. Concerti a 2, 3, & 4 voci, libro 1. Motetti a 3, 4, 5, & 6 voci, libro 7mo. Novelli fiori a 2 & 3 voci, libro 6. Litanie di B. V. a 3 voci: and, lastly, he published at Venice, 1622, a work intitled "Gemme Sacre," and in the same city, 1629, another book of motets. Walther.

MILLEVILLE, in *Geography*, a town of Sweden, in the province of Warmeland; 25 miles S. of Carlstadt.

MILLIARE, or MILLIARIUM, among the Romans, denoted *a mile*, consisting of a thousand paces, *mille passus*; whence the name.

In the Roman empire, the milliaria, in all the great roads, were marked with stones, or columns erected for that purpose; commencing from a column in the heart of the city, called *milliare aureum*.

Those columns were also hence denominated *milliary columns*.

MILLIARIA COHORS. See COHORS *Equitata*.

MILLICO, GIUSEPPE, of Naples, in *Biography*, arrived in England 1772, from Vienna, where he had acquired great applause as a singer and actor, in Gluck's operas of "Orfeo," "Alceste," and "Paride ed Elena," and as a singing master, by making Gluck's niece one of the most expressive singers then alive.

This judicious performer and worthy man, who was not an Adonis in person, and whose voice had received its greatest beauties from art, found the musical part of our nation in no favourable disposition towards him. The admirers of Tenducci and Guadagni, as well as the Cocchi, Guglielmi, Giardini, Vento, and Bach parties, however hostile in other particulars, all agreed in decrying every part of that opera in which their favourite had no concern. Sacchini, who arrived here soon after, was involved in these cabals. None of the friends of their predecessors would allow that Millico could sing or the new master compose. Violent and virulent means were used to poison, or at least to shut the ears of the unprejudiced public; but not with much success. Indeed, at first both the music and performance were frequently hissed: but, at length, Sacchini's compositions were generally allowed to be admirable, and Millico's importance was manifested by a crouded house at his benefit, composed of the first persons for taste and rank in the kingdom; and at the end of the next season, several who had boldly pronounced that neither Sacchini could compose nor Millico sing, would have given a hundred pounds if they could have recalled their words, or made their acquaintance forget they had been guilty of such manifest injustice and absurdity.

The canzonets of his composition, in singing which he used to accompany himself on a small harp slung over his shoulder, are still as *musicadi camera*, elegant and pleasing. Not many years after he left this country, where he remained two seasons, he was afflicted with blindness; but being received in the chapel royal at Naples, he performed in that melancholy state a considerable time, till other infirmities came on, when he threw himself into a convent to end his days. He was living when the French invaded Naples; but whether the turbulence of the times suffered him to live or die in peace, we are unable to affirm.

MILLIGRAMME, in *Commerce*, a French measure of weight = .0154 English grains. See WEIGHT.

MILLILITRE, a French measure of capacity = .06103 English cubic inches. See MEASURE.

MILLIMETRE, a French measure of length = .03937 English inches. See MEASURE.

MILLING, in the *Manufactories*, an operation called also *fulling*.

MILLING, or *throwing of silk*, is the last preparation of silk before dyeing; serving to twist it, more or less, according to the work for which it is intended.

To prepare the silk for milling, they first put it in boiling water, inclosed between two linen cloths. The mill is a square machine, composed of several pieces of wood, mortised in each other, so as to form a kind of large cage, in the centre of which are two wheels placed parallel over each other, whose axis bears on two posts. When the machine is simple, a single man turns these wheels by means of a little cog, in which they catch, and a large handle.

The wheels, put in motion by the handle, communicate their motion to eight windles, or reels, or even more, according to the largeness of the machine; on the slights or arms of which the silk is wound from off two rows of bobbins placed on each side of the machine; each row at the height of one of the two wheels in the centre. These bobbins have their motion by means of leathern thongs, which bear on little cylinders of wood that support them, and turn at length on the two wheels at the centre; so that the silk on each bobbin twists as it winds, and forms its separate skain.

The smallest wheel moves two hundred of these bobbins, over which a single person is sufficient to inspect, to put new bobbins or spoils in lieu of those discharged of their silk, and to knot the ends when they break. See WINDING *of Silk*.

MILLINGTONIA, in *Botany*, a supposed new genus, consecrated by the younger Linnæus, to the memory of sir Thomas

Thomas Millington, Savilian profeffor at Oxford, who is recorded by Grew to have firft fuggefted to him that the anthers of plants were their male organs.—Linn. Suppl. 45. Schreb. 425. Willd. Sp. Pl. v. 3. 382. (where the name is thrice written *Mallingtonia*, by mere inattention.) Juff. 138. Clafs and order, *Didynamia Angiofpermia*. Nat. Ord. *Perfonatæ*, Linn. *Bignoniæ*, Juff.

The fruit being unknown, the generic character in the *Supplementum* has always been incomplete, and is now found infufficient to diftinguifh the plant in queftion from *Bignonia*, to which genus it is referred by Dr. Roxburgh.

Bignonia fuberofa. Roxb. Coromand. v. 3. 11. t. 214. (Millingtonia hortenfis; Linn. Suppl. 291.)—Koenig firft obferved this fine tree in the gardens of the Rajah at Tanfchuhr, or Tanjore, but did not meet with the fruit. His manufcript however does not imply that none is ever produced there. From hence fome plants were brought to Madras, and one to Calcutta, where Dr. Roxburgh informs us it is now an elegant tree, about thirty feet in height, bloffoming at the clofe of the rainy feafon, and ripening feeds in March. The *trunk* is ftraight, with a light afh-coloured, deeply cracked, fpongy bark. *Leaves* oppofite, repeatedly pinnate, about two feet long; leaflets ovate, pointed, fmooth, ferrated in Roxburgh's figure, but in his defcription, like the Linnæan fpecimens, entire, and conveying fome idea of the foliage of Catalonian Jafmine. *Panicles* terminal, large, crofs-branched, many-flowered, fmooth. *Flowers* two inches long, tubular, flender, white, delightfully fragrant; their upper lip erect, cloven half-way down; lower in three equal, ovate, three-ribbed, reflexed fegments. *Pod* a foot long, not an inch broad, compreffed, nearly fmooth, pointed at each end. *Seeds* winged.—The native country of this plant has not yet been afcertained.

Millingtonia is now applied as the name of a new Eaft India genus in *Diadelphia Decandria*, by Mr. Donn in *Hort. Cant.* ed. 5. 180. Of this we prefume Mr. Brown to be the author, and that it will be defined in the new edition of Mr. Aiton's *Hortus Kewenfis*. Three fpecies are enumerated by Mr. Donn, *M. trinervia*, *ftricta*, and *femialata*; all ftove fhrubs, which feem not yet to have flowered at Cambridge. This genus is placed between *Hedyfarum* and *Indigofera*.

MILLION, in *Arithmetic*, the number of ten hundred thoufand; or a thoufand times a thoufand.

A million of gold, or million of money, is fometimes underftood of a million of pounds; and fometimes of a million of crowns.

Million *Bank*. See Bank.

MILLMOTH, in *Natural Hiftory*, the name of an infect approaching to the nature of the beetle, but having no fheath wings. It is common in the abode of millers and bakers, and other perfons who deal in meal.

MILLOT, Claude-François-Xavier, in *Biography*, a well-known French writer, was born at Befançon in 1726. He was brought up among the Jefuits, and devoted himfelf to the duties of the pulpit; but when the period for public exertion arrived, either the weaknefs of his voice, or a natural timidity, convinced him that he could not make progrefs as a public orator. He, therefore, undertook a profefforfhip of hiftory at Parma, by the recommendation of the prince. He filled this office with high reputation, and upon his return to France was appointed preceptor to the duke d'Enghien. He died in the year 1785, at the age of 59. D'Alembert faid of the abbé Millot, that he was the perfon of all others whom he had known, that had "the feweft prepoffeffions and the feweft pretenfions." In fociety he was modeft and rather referved in his manners, but every thing which he faid was fenfible and judicious. His works alfo exhibit the fame candour and cool judgment which were vifible in his converfation. They are chiefly hiftorical abridgments, written with care and correctnefs, in a natural and rather elegant ftyle. The principal are: "Elemens de l'Hiftoire de France, depuis Clovis jufqu'à Louis XV.," 3 vols. 12mo.; "Elemens de l'Hiftoire Univerfelle, "9 vols. 12mo.; "Memoires Politiques et Militaires pour fervir à l'Hiftoire de Louis XIV. et de Louis XV.," &c. He publifhed alfo "L'Hiftoire des Troubadours," in 3 vols. which work was chiefly drawn from the papers of M. de Sainte Palaye; fome "Difcourfes" read before the academy of which he was a member, and a tranflation of felect harangues from the Latin hiftorians.

MILLOWITZ, in *Geography*, a town of Bohemia, in the circle of Saatz; 10 miles W. of Saatz.

MILLSTREET, a poft-town of Ireland, in the county of Cork, chiefly remarkable for a good inn, at which travellers to Killarney ufually pafs a night. It is 134 miles S.W. from Dublin.

MILLTOWN, a town of America, in the ftate of Delaware; two miles from Wilmington.—Alfo, a town in Northumberland county, Pennfylvania, on the E. fide of the W. branch of Sufquehannah river, containing about fixty houfes; 14 miles N. by W. of Sunbury.

Milltown, a poft-town of Ireland, in the county of Kerry, which promifes to become a good market town by the exertions of fir William Godfrey, and the convenience of water carriage, the tide bringing floops up the Mang very near to this town. It is 169 miles S.W. by W. from Dublin, and nine miles N.W. from Killarney. Carlifle.

MILLVILLE, a poft-town of Cumberland county, New Jerfey; 196 miles N.E. from Wafhington.

MILLWOOD, a poft-town of Frederick county, Virginia; 68 miles from Wafhington.

MILNTHORP, or Milthorp, a fea-port and market-town in the parifh of Heverfham, Kendal ward, Weftmoreland, is fituated near the mouth of the Can, at the diftance of five miles from Kendal, and 251 from London. It confifts chiefly of one ftreet, which is pretty well built; and at the E. end there are fome good houfes, in pleafant and open fituations. This town is the only fea-port in the county, and has feveral veffels belonging to it, which trade principally to Liverpool, Port Glafgow, and Annan in Scotland. Here are three rope-yards, two paper-mills, one flax-mill, and one cotton-mill. The market day is Friday, and there is an annual fair on Old May day. A very handfome bridge is thrown acrofs the river Betha, which flows through the town. The refident population here, according to the parliamentary returns of 1801, amounted to 968 perfons; 459 males, and 509 females, of which number 113 were returned as employed in agriculture, and 170 in trade and manufactures.

The country around this town is pleafingly diverfified with hill and dale, and embellifhed by a variety of elegant manfions. Of thefe that of Dallam Tower, the feat of Daniel Wilfon, efq. is the moft confpicuous. It is fituated at the foot of a hill, which rifes rapidly from its bafe, and is covered to the fummit by a profufion of trees. In front extends a fine park, adorned with wood, the ground of which rifes as it recedes from the houfe. At Beerham-hill, near this manfion, is a waterfall on the river Beele, well deferving the attention of the curious traveller. Houfman's Topographical Defcription of Cumberland, Weftmoreland, &c. 8vo. Carlifle's Topographical Dictionary, 4to.

MILO, in *Biography*, a name that frequently occurs in the Roman claffics: we fhall notice three perfons of note.

One was celebrated at Crotona, in Italy. It is said that he carried on his shoulders a young bullock four years old, and afterwards killed it with a single blow of his fist. He was seven times crowned at the Pythian games, and six times at Olympia.—The second was Titus Annius, a native of Lanuvium, who attempted to obtain the consulship at Rome. Clodius the tribune opposed his views, yet Milo would have succeeded, had not an unfortunate circumstance taken place between his suite and that of Clodius as he was going to the country. Clodius and eleven of his servants were killed, and the body of the murdered tribune was carried to Rome and exposed to public view. Cicero, as is well known to every classical student, undertook the defence of Milo, but with no effect; he was condemned and banished to Massalia.—A third of this name was a general of the forces at Tarentum, and that he might not forget the duty and allegiance which he owed to his sovereign, Pyrrhus sent him, as a present, a chain, which was covered with the skin of Nicias the physician, who had perfidiously offered the Romans to poison his sovereign for a sum of money.

Milo, anciently *Melos*, in *Ancient Geography*, one of the largest and most elevated islands in the southern part of the Grecian Archipelago. According to Thucydides, it was independent, and enjoyed perfect freedom long before the Peloponnesian war. The inhabitants, strongly solicited by the Athenians on the one hand, and on the other attached to the Lacedæmonians, from whom they had descended, wished, in the midst of this terrible war, to remain quiet and to observe a wise neutrality. At this conduct the Athenians were so irritated, that they dispatched Nicias with a fleet of sixty ships, and 2000 land forces to punish them for refusing to furnish their quota of troops. Nicias ravaged this island, but failed with his feeble army to take the town, which was defended by all the inhabitants, assembled for this purpose. Some time after the Athenians sent two other generals, with a more numerous army, who were not more successful than Nicias; but at length, when Philocrates brought fresh troops, the Miliots were reduced to the greatest extremity, and obliged to surrender. The Athenians, implacable in their resentment and ferocious in their vengeance, massacred, without discrimination, all the men who were capable of bearing arms, and made slaves of the women and children, whom they carried away to Attica. They then sent 500 persons to repeople the island, and to take possession of the property of those whom they had murdered. In the mean time, the Athenians, conquered in their turn by Lysander, commander of the Lacedæmonian troops, and compelled to surrender at discretion, found themselves constrained to recal their colony; and those who remained of the unfortunate Miliots were then enabled to return, and to reinvest themselves with the property which had been taken from them. This island, like all those of the Archipelago, passed under the dominion of the Romans; it afterwards made part of the empire of the East. Marco Santo united it, with all the Cyclades, to the duchy of Naxos; and it was in process of time detached from this duchy in favour of Francesco Crispo; and at length subjected to the Ottoman empire, under which it has lost, together with its liberty, its importance.

Milo is about sixty miles in circumference; it is divided in its middle, and almost through its whole breadth, by a deep bay: this is one of the finest harbours in the Mediterranean, sufficiently spacious to contain a fleet, and to keep the ships belonging to it sheltered from all winds. The anchorage is excellent, particularly at the head of the gulf and near the E. coast; the bottom has a fine sand, and vessels come to anchor there in from 12 to 18 fathom water. Small craft can approach nearer the coast, and carry out moorings to the rocks of one of the grottoes. Another anchorage, more convenient, and also less exposed to the action of the winds and the violence of the sea, lies on the W. coast, in a cove called "Patricha."

The entrance of the harbour first mentioned faces the N.W.; it is very wide, and ships approach very near to the coasts that form it, without risk. To the starboard, or right, they have Cape Veni, and to the left Cape Lerida; the gulf then contracts between Cape San Dimitri and Cape Bombarda. As the latter, a high mountain, in the form of a sugar-loaf, bears on its summit a village, called "Sifour," surrounded by walls, whence it has the name of Castro: here the pilots for the Archipelago reside. As the air here is pure and wholesome, it is more populous than the capital of Milo, and the inhabitants exhibit signs of vigour and health, not common in other parts of the island. It is not improbable that the principal place of the isle of Milo was near the scite of Sifour, which commands an extensive prospect; more especially as the ancient habitations of the Archipelago are built on eminences the most lofty, and the most rugged of access. Near this place are considerable ruins, fragments of columns of Parian marble, and subterraneous galleries, antique catacombs, which furnish funeral inscriptions, vases, idols, and medals, and other remains of a considerable city. The women of Sifour, or Sefours, employ themselves the whole year in knitting cotton stockings, and making coarse calicoes. The men cultivate the earth, or are mariners. Near this place, on the summit of a hill, is at present a church of Caloques, built, as Olivier conceives, on the ruins of a temple. However, the capital of the island is a town of the same name, situated on a plain formerly not inferior to any other of the Archipelago, but now presenting scarcely any thing but ruins. Scarcely do forty families drag on their unfortunate existence, with consumptive aspects, in a town which reckoned 5000 inhabitants within its walls. At the beginning of the last century, Tournefort discovered, in 1700, that the air of Milo was insalubrious, and that the inhabitants were subject to dangerous disorders; but the unwholesomeness of the air must have increased very much since that epoch. In traversing the island to the monastery of St. Marino, Mount St. Elias, the most lofty point in the island, and the volcanic mountain of Calamo, the country presents various traces of its volcanic origin. At the distance of a quarter of a league from Milo alum is formed, which has been mentioned both by ancient and modern writers. In the same grotto that furnishes this alum, are also found crystals of gypsum, but the heat is such as not to admit its being examined for any long time. The baths called "Loutra" were also situated in this quarter. The water is strongly charged with alum and marine salt. These baths were anciently much frequented by Greeks, who repaired hither from all the Cyclades in order to obtain relief in disorders of the skin, as well as in rheumatism and palsy. Spacious grottoes occur frequently, and in these are subterraneous caverns, full of turnings and twinings, and into which the descent is steep and laborious. The chambers which they contain appear to have been formerly used as habitations and places of concealment.

Near the scite of an ancient town, called "Clima" by the modern Greeks, are sepulchres or catacombs, in which, at an unknown period, the inhabitants of Milo deposited their dead. Each of these catacombs generally contains seven sarcophagi five and a half or six feet long, and a foot or fifteen inches deep, surmounted by an arch and dug in the rock. The whole island indicates a subterraneous conflagration; and in feveral places the ground which refounds under your feet apprizes you that it covers vaft cavities. Every appearance teftifies, that the ftones and pebbles which are found here have been thrown up by the explofion of a volcano; boiling waters iffue on all fides; pumice ftones are fcattered abroad; fulphur is formed in abundance, and fhews itfelf on the furface of the ground. Neverthelefs, the vegetable earth, which moftly covers the ifland, gently warmed by fubterraneous heat, is very productive. Corn and cotton are here of an excellent quality; the vines yield good wine, and the trees afford delicious fruits; but the quantity of lands that lie fallow announces an exceffive diminution in the population, as well as the criminal indifference of the government. Ships ftill come to Milo to fetch away a great quantity of the folid lava, of which mill-ftones are made, which are tranfported to feveral countries of the Levant, particularly to Egypt and Conftantinople. The ifland likewife contains many mines of iron and ferruginous pyrites, from which no advantage is derived. Under a liberal adminiftration other valuable articles might be found, and the ifland might even ceafe to be an unhealthy abode. The whole population at prefent does not amount to 500 perfons, and this fmall number would daily decreafe, if it was not kept up by emigrants from the Morea, where diftrefs conftrains them to feek new habitations, and who are attracted to Milo with a view of cultivating the lands. The captain-pacha has fome difficulty in levying 2500 piaftres by way of impoft. N. lat 36° 40′. E. long. 24° 30′. Sonnini and Olivier.

MILOPOTAMO, in *Geography*, a town and fortrefs of the ifland of Candia; 28 miles W.N.W. of Candia.

MILORRA, a fmall ifland in the Eaft Indian fea, between Ternate and Tidor.

MILOSLAW, a town of the duchy of Warfaw; 20 miles S.S.W. of Gnefna.

MILPHOSIS, μιλφωσις, a Greek word ufed by the ancient medical writers, as a name of the difeafe of the eye-lids, by which the hairs fall off from them, and the edges become red and tumid.

MILREA, or MILREE, in *Commerce*, a money of account in Portugal, fo called, becaufe 1000 reas, or rees, are = 1 milree. In the notation of accounts, the milrees are feparated from the rees by a croffed cypher, called "Cifraon," and the milrees from the millions by a colon; thus, Rs. 2 : 700 ⊕ 500, means two thoufand feven hundred mil. and five hundred rees. As the crufado of exchange, or old crufado, is 400 rees, the new crufado, 480 rees, the teftoon, 100, and the vinten or vintem, 20 rees; the milree is = $2\frac{1}{2}$ old crufados = $2\frac{1}{12}$ new ditto = 10 teftoons = 50 vintens. The milree valued in gold is worth $67\frac{1}{4}d.$ fterling, and the fame in filver is worth $68\frac{3}{4}d.$ fterling. The milree is alfo a gold coin, ftruck for the Portuguefe poffeffions in Africa in 1755; it weighs $19\frac{3}{4}$ grains, and contains, in pure gold, 18.1 grains, and is valued at $3s.\ 2\frac{1}{2}d.$ fterling. See COIN.

MILSTATT, or MUHLSTADT, in *Geography*, a town of the duchy of Carinthia, fituated on the Milftatter fee: 40 miles N. of Goritz. Milftatter fee is a lake of Carinthia, 9 miles E. of Saxenburg.

MILT, in *Anatomy*, a popular name for the fpleen.

MILT, or *Melt*, in *Natural Hiftory*, the foft roe in fifhes; thus called becaufe it yields, by expreffion, a whitifh juice refembling milk. See ROE.

The milt is properly the feed, or fpermatic part of the male fifh.

The milt of a carp confifts of two long whitifh irregular bodies, each included in a very thin fine membrane. M. Petit confiders thefe as the tefticles of the fifh wherein the feed is preferved: the lower part, next the anus, he takes for the veficulæ feminales. Vide Mem. Acad. R. Scien. anno 1733, p. 291.

In the milt of a living cod-fifh there are fuch incredible numbers of thofe fmall animalcules found in the male feed of all animals, that in a drop of the juice of it, no more in quantity than a fmall grain of fand, there are contained more than ten thoufand of them; and, confidering how many fuch quantities there are in the whole milt of one fuch fifh, it is not exceeding the bounds of truth to affirm, that there are more animals in one milt of it, than there are living men at one time upon the whole face of the earth. However ftrange and romantic fuch a conjecture may appear at firft fight, a ferious confideration, and calculation, will make it appear very plain. A hundred fuch grains of fand as here mentioned, will make about an inch in length; therefore in a cubic inch there will be a million of fuch fands.

The milt of one of thefe fifhes is frequently about the quantity of fifteen cubic inches, it muft therefore contain fifteen millions of quantities as big as one of thefe fands; and if there be ten thoufand animals in each of thofe quantities, there muft be, in the whole, a hundred and fifty thoufand millions: which is a number vaftly exceeding the number of mankind, even though we were to fuppofe the whole earth as populous as Holland. See Philofophical Collections, p. 4. See *Fecundity of* FISH.

MILT *Wafte*, or *Ceterach afplenium*, in *Botany*. (See ASPLENIUM.) The leaves are recommended as a pectoral fimilar to maidenhair, or Afplenium trichomanes; to which they have been frequently joined in infufions and apozems; and likewife as an aperient in obftructions of the vifcera. They poffefs likewife a diuretic virtue, and appear to gently carry off fand, cleanfe the kidnies, and allay pains in the urinary paffages. The way of ufing them is to drink infufions of them in the morning, as tea, with the addition of fuch other medicines as particular cafes may require. See CETERACH, ASPLENIUM, and TRICHOMANES.

MILTENBERG, in *Geography*, a town of Germany, on the Maine; 26 miles N.E. of Heidelberg.

MILTHORP. See MILNTHORP.

MILTIADES, in *Biography*, a celebrated Athenian general, the fon of Cimon, and grandfon of Miltiades, who founded an Athenian colony on the Thracian Cherfonefus. After the affaffination of Stefagoras, in the colony, Miltiades was fent from Athens to take the command, and having got into his power the principal men of the Cherfonefians, he made himfelf mafter of the whole diftrict, and married the daughter of the king of Thrace. When Darius I., king of Perfia, undertook an expedition againft the Scythians, and throwing a bridge acrofs the Danube marched into their country, he entrufted the guard of the bridge to the Ionian Greeks, the commanders of whom he had attached to himfelf, by raifing them to the fupreme authority in their feveral cities. Miltiades, who was one of them, excited by that fpirit of Grecian patriotifm, to which every other duty was made fubfervient, urged the other leaders to break down the bridge, in order that a prince fo entirely inimical to Grecian liberty might never return in fafety. His counfel was approved by all the reft except Hyftiæus the Milefian, who had influence enough to prevent its taking effect. Miltiades, judging it imprudent to await the monarch's return, embarked for Athens, and in his way took poffeffion of the ifle of Lemnos for his countrymen. Darius, after his return from his Scythian expedition, having refolved upon the conqueft of Greece, fent Mardonius at the head of a powerful army to invade it. When he had arrived at the

the plains of Marathon, within ten miles of the capital, Athens, the alarm of the citizens became extreme, and in their despair they took the resolution to march out to meet the foe, with such troops as they could assemble, soliciting, at the same time, succours from the other Grecian states. But of the battle of *Marathon*, we have already given an account under that article. Miltiades, who was unquestionably the grand instrument in obtaining this victory, was next entrusted with a strong armament fitted out for the reduction of some of the islands which had taken part with the Persians. He sailed to Paros, and laid siege to its capital, but either a false alarm of the approach of the Persian fleet, or an unsuccessful attempt to gain the place, in which he was wounded, caused him to return without effecting his purpose. The disappointment of the Athenians was so great, that Miltiades was accused of treason before the assembly of the people, who, forgetting his past services, by which they had been delivered from a foreign yoke, condemned him to death. Upon, however, the payment of a heavy fine, he was exempted from capital punishment, but was thrown into prison, where, to the everlasting disgrace of his countrymen, he died of a broken heart, in the year after the battle of Marathon. Corn. Nepos. Univer. Hist.

MILTON, John, in *Biography*, the father of our great poet, though a scrivener (or banker) by profession, was a voluminous composer, and equal in science, if not genius, to the best musicians of his age; in conjunction, and on a level with whom, his name and works appeared in numerous musical publications of the time, particularly in those of old Wilbye; in the "Triumphs of Oriana," published by Morley; in Ravencroft's "Psalms;" in the "Lamentations," published by sir William Leighton; and in MS. collections, still in the possession of the curious The late Mr. T. Warton, in his notes on the Minora of Milton, tells us, from the MS. Life of the Poet, by Aubrey, the antiquary, in the Mus. Ashm. Oxon. that "Milton's father, though a scrivener, was not apprenticed to that trade: having been bred a scholar, and of Christ-church, Oxford; and that he took to trade in consequence of being disinherited." Mr. Warton therefore observes, that Milton, in his Latin epistle to his father, addresses him in a language which he understood. Aubrey adds, "that the elder Milton died very old in 1647, and was interred from his house in Barbican, in St. Giles's church, Cripplegate; where the great poet was afterwards buried, near his father, in 1674."

His son celebrates his musical abilities in an admirable Latin poem, "Ad patrem," where, alluding to his father's musical science, he says, that Apollo had divided his favours in the sister arts between them; giving music to the father, and poetry to the son.

"Nec tu perge, precor, sacras contemnere musas,
Nec vanas inopesque puta, quarum ipse peritus
Munere, mille sonos numeros componis ad aptos,
Millibus et vocem modulis variare canoram
Doctus, Arionii merito sis nominis hæres.
Nunc tibi quid mirum, si me genuisse poetam
Contigerit, charo si tam prope sanguine juncti
Cognatas artes, studiumque affine sequamur?
Ipse volens Phœbus se dispertire duobus,
Altera dona mihi, dedit altera dona parenti,
Dividuumque Deum genitorque puerque tenemus."
Ver. 56. usque 66.

His effusions of gratitude for the education he had received from his parent's bounty, and his apology for cultivating poetry, of which he gives a charming eulogium, seem to contain ideas as beautiful and sublime, as any in his Paradise Lost.

Milton, John, the most illustrious of English poets, was descended from an ancient family settled at Milton, in Oxfordshire. His father, who had been brought up in the Roman Catholic religion, and by embracing the Protestant faith had been disinherited, came to London and followed the profession of a scrivener, and marrying a woman, exemplary for her numerous virtues and extensive charities, had two sons and a daughter; *viz.* John, the subject of this article, Christopher, and Anne. Of the two latter, Christopher, applying himself to the study of the law, became a bencher of the Inner Temple, and at an advanced period of his life was knighted, and raised by James II., first to be a baron of the exchequer, and afterwards one of the judges of the court of Common Pleas. During the civil war he followed the royal standard, and effected his composition with the victors by the prevailing interest of his brother. In his old age he retired from the fatigues of business, and closed, in the country, a life of study and devotion. His sister, Anne, married Mr. Edward Philips, a native of Shrewsbury, who, coming to London, obtained the lucrative place of secondary in the crown office in chancery: by him she had several children, of whom Edward and John only survived to maturity; the former became the biographer, after having, with his brother, been the pupil of his uncle, our author. By a second husband, Mr. Agar, she had two daughters, of whom Mary died young, and of the other, Anne, nothing more is known, than that she was living in the year 1694.

John Milton, the subject of the present article, was born at his father's house, in Bread-street, London, on the 9th of December, 1608. His promise of future excellence was made at a very early period: every incitement to exertion, and every mode of instruction adapted to the disposition and powers of the child, were employed, and no means, probably, were omitted to expand the intellectual Hercules of the nursery into the full dimensions of that mental amplitude for which he was intended. The portrait of him was painted, when he was only ten years old, by the celebrated Cornelius Jansen; hence we may infer that the son, who was made the object of so flattering a distinction by a father, in competent, but by no means in affluent circumstances, could not have been a common child. Of himself, at this period, he gives the following account. "My father destined me, when I was yet a little boy, to the study of elegant literature, and so eagerly did I seize on it, that from my twelfth year, I seldom quitted my studies for my bed till the middle of the night. This proved the first cause of the ruin of my eyes; in addition to the natural weakness of which organs, I was afflicted with frequent pains in my head. When these maladies could not restrain my rage for learning, my father provided that I should be daily instructed in some school abroad, or by domestic tutors at home." "How great," says Dr. Symmons, "are the obligations of Britain and the world to such a father, engaged in the assiduous and well directed cultivation of the mind of such a son." Some part of his early education was committed to the care of Mr. Thomas Young, a puritan minister, and native of the country of Essex, afterwards chaplain to the English merchants at Hamburgh, a man whose merits are gratefully commemorated by his pupil in a Latin elegy. About the age of fifteen he was sent to St. Paul's school, of which Mr. Alexander Gill was then master, and there he began to distinguish himself by his intense application to study, and his poetical talents. Ardent in his love of knowledge, he was regardless of pleasure, and even of health, when they came into competition with the prevailing paſſion of his ſoul, and we are conſequently not ſurprized by the extraordinary and brilliant reſult which ſoon flaſhed upon the world. It is conjectured that it was at this early period he imbibed the ſpirit of devotion which actuated his boſom to his lateſt moments. For this he was probably indebted to his father, who would naturally be ſolicitous to ſtamp upon the tender boſom of his ſon, that conviction and feeling of duty which were impreſſed ſo deeply on his own, and which he had exhibited in his abjuration of thoſe errors in which he had been educated. He intended his ſon for the church, and on that account would be more anxious to incline him to devotional principles and practice. The ſentiments and the warmth thus communicated to the mind of the youth, would unqueſtionably be ſtrengthened by the leſſons and example of his preceptor, Mr. Young, in whom religion was carried to enthuſiaſm. To Milton's devotional turn of mind we are probably indebted, not merely for the ſubject, but for a great part of the ſublimity of the Paradiſe Loſt. On the 12th of February, 1624-5, he was entered a penſioner at Chriſt's college, Cambridge, under the tuition of Mr. W. Chappel. Of his courſe of ſtudies in the univerſity little is known, but he gave proof of the extraordinary ſkill he had acquired in writing Latin verſe, by ſeveral exerciſes preſerved among his works, and which are of a purer claſſical taſte than any preceding compoſitions of the kind by Engliſh ſcholars. It appears that ſome part of his conduct brought upon him academical puniſhment; but whatever were the cauſe, he felt no ſhame on account of it, but refers ſpontaneouſly to the circumſtance in the following lines:

> "Nec duri libet uſque minas perferre magiſtri
> Cæteraque ingenio non ſubeunda meo.
> Si ſit hoc exilium patrios adiiſſe penates
> Et vacuum curis otia grata ſequi."

Which have been tranſlated by his biographer.

> "And ill my ſoul a maſter's threats can bear,
> With all the fretting of the pedant's war.
> If this be baniſhment—all cares aloof—
> To live my own beneath a father's roof—
> Still let an idle world condemn or not,
> Mine be a truant's name,—an exile's lot."

From theſe lines, the enemies of Milton have inferred that he was ſubjected to corporal puniſhment, and that he was diſmiſſed from his college for irregularity of conduct. Dr. Symmons has, with a proper degree of indignation, vindicated completely the character of Milton from theſe vile aſperſions. Our limits will not permit us to follow him through the ſteps of the arguments, but they appear perfectly ſatisfactory. The doctor, ſpeaking of the calumnies ſpread on this ſubject, ſays, "In oppoſition to this pretended evidence, ſtand the records of our author's univerſity, and the force of his own poſitive declarations. By the former of theſe, which prove that he took his bachelor's degree as ſoon as it could be taken, it is made highly probable, if not abſolutely certain, that he loſt no term; and by the latter we are aſſured that he was not only exempted from puniſhment during his continuance at Cambridge, but in that ſeat of learning was an object of affection and reſpect."—And again, "With reſpect to Milton, we may be confident that no immorality could be the cauſe of his puniſhment. Religion, as we know, took early poſſeſſion of his boſom, and he who, with weak eyes and an aching head, could conſecrate one-half of the night to ſtudy, cannot be ſuſpected of ſtealing the other half from repoſe, for the purpoſe of confounding it with exceſs, or of polluting it with debauch. A mind, indeed, like his, exulting in the exerciſe of its higher powers, and intent on the purſuit of knowledge, could not, without a violation of its nature, ſubmit to licentious indulgencies. The cultivation of intellect not only diveſts the attention from ſenſual pleaſure, but inſpires a pride which ſubdues its faſcination: and while the ſpectacle of the world exhibits innumerable inſtances of men of genius hurrying into exceſſive gratification, it ſcarcely preſents us with one, under the influence of the ſame unfortunate error, among the aſſiduous votaries of knowledge."

Milton probably became obnoxious to the governors of his college by the bold avowal of his puritan opinions, which he had imbibed from his tutor Young, or by his diſlike to the diſcipline of the eſtabliſhed religion, or to the plan of education purſued in the univerſity; hence he might loſe the favour of his ſuperiors in the college, and be expoſed to their cenſures without incurring the ſlighteſt loſs of character, or ſuſtaining the moſt trifling diminution of general eſteem.

He took the degrees of bachelor and maſter of arts, the latter in 1632, when he left the univerſity. In the ſeven years of his academical life, his vigorous and ardent genius broke out in frequent flaſhes, and evidently diſcloſed the future author of "Comus" and "Paradiſe Loſt." He was a poet when he was only ten years old, and his tranſlation of the 136th pſalm evinces his progreſs in poetic expreſſion at the early age of fifteen. He renounced his original purpoſe of entering the church, for which he aſſigns as a reaſon, "that coming to ſome maturity of years, he had perceived what tyranny had pervaded it, and that he who would take orders, muſt ſubſcribe ſlave, and take an oath withal, which, unleſs he took with a conſcience that could retch, he muſt either ſtrain, perforce, or ſplit his faith; I thought it better to prefer a blameleſs ſilence before the office of ſpeaking, bought and begun with ſervitude and forſwearing." This denotes a mind reſolved to think and act for itſelf, and it cannot be doubted that Milton was already marked with that firm unyielding temper, which, in ſome degree, is a neceſſary concomitant of a ſuperior mind. He now returned to his father, who had retired from buſineſs, to a reſidence at Horton, in Buckinghamſhire, and there paſſed five years in a courſe of claſſical ſtudy, and in the compoſition of ſome of his fineſt miſcellaneous poems. This was the period of his Allegro and Penſeroſo, his Comus and Lycidas. "L'Allegro and Il Penſeroſo," ſays Dr. Symmons, "were certainly written at Horton, and probably at no long period before the Lycidas, which was the laſt of our author's works while he reſided with his father. They were compoſed in the happieſt humour of the poet's mind, when his fancy was all ſun-ſhine, and

> ——— no cloud, or, to obſtruct her view,
> Star interpoſed.

We may contemplate them not as the effects or qualities, but as the very ſubſtance of poetry, as its "hidden ſoul untied, and brought forward to our ſight." In comparing the merits of theſe pieces, Dr. S. gives the preference to Il Penſeroſo. "The portrait of contemplation," ſays he, "the addreſs to Philomel; the image of the moon wandering through heaven's pathleſs way; the ſlow ſwinging of the curfew over ſome wide-watered ſhore; the flaming of the night lamp in ſome lonely tower; the unſphering of the ſpirit of Plato to diſcloſe the reſidence of the unbodied ſoul; the arched walks of twilight groves; the myſterious dream by the murmuring waters; the ſweet muſic of the friendly ſpirit of the wood; the pale ſtudious cloiſter; the religious light thrown through the ſtoried windows; the pealing organ, and finally the peaceful hermitage—

form together such a mass of poetic imagery as was never before crowded into an equal space: the impression made by it on the imagination is to be felt and not explained." The pale and studious cloister having been objected to, in one of Mr. Wharton's criticisms, Dr. Symmons remarks, that the word *pale*, as an epithet to cloister, is most happily poetic, and as holding a large and animated picture to the imagination. It shews the ghostly light of the place, the sickly cheek of timorous superstition, and the wan and faded countenance of studious and contemplative melancholy.
